Tonics, in general, are freely employed; and, of these, the Peruvian bark is the principal remedy from the vegetable kingdom; yet alone it is seldom trusted, and would probably seldom succeed. The metals, we have said, are very generally tonic, differing only in the degree of inflammatory stimulus, most conspicuous in iron. All have, however, been employed, viz. silver (argentum nitratum); iron (flores martiales, ferrum vitriolatum, rubigo ferri, squamæ ferri, and chalybs preparatum); copper (cuprum vitriolatum and ammoniacum); zinc (zincum vitriolatum, ustum); tin (limatura vel pulvis stanni); arsenic (kali arsenicatum). Each has been used with success; but the silver, the copper, and zinc, have been preferred. These are more effectual when combined; but as we cannot suspect any chemical union, the increased power is probably owing to their being borne by the stomach in increased quantities. (See COMBINATION OF MEDICINES). As a tonic, the cold bath is also an excellent remedy.

The medicines which obviate irritation are the sedatives and antispasmodics. Of these the chief is opium, and the valerian: camphor is similar in its powers; and the leaves of the orange tree, the extractum hyoscyami, the peony root, flowers of the cardamine pratensis, are medicines of the same class. We have found little benefit from any except the valerian and camphor. The flowers of the cardamine have failed in every instance; the leaves of the orange tree have produced only a temporary and inconsiderable benefit. The union, however, of these with the tonics has been particularly serviceable; and their effects seem to support the opinion we have attempted to establish. The bark and valerian united have afforded relief, which neither separately could procure; and the camphor, with the zinc, been highly and deservedly commended. Opium has been combined with all the metallic preparations with advantage. If, according to this idea, such combinations are pursued, much benefit will probably result.

The tribe of antispasmodics has been employed; but not often successful. The ether, rectified animal oil of Dippel, oleum vini, musk, castor, and asafoetida, are the principal remedies of this class; but they are seldom trusted alone; and of their separate or comparative merits it is not easy to speak. We have placed them nearly in the order of their power.

Of anthelmintics we have not spoken with sufficient distinctness. Worms are not an uncommon source of irritation in the tender habits of children; and epileptic paroxysms should always, in such cases, be attacked with this remedy, unless they arise from fright, or some more obvious cause. We have nothing to add at present to what we have remarked in the article ANTHELMINTICS, q. v.

See Hippocrates, Celsus, Cœlius Aurelianus, Aretæus, Hoffman, Boerhaave; and among the best authors on this subject, Threlfal's and Lyson's Essays on Epilepsy; Cullen's First Lines, vol. iii. edit. 4.

EPIME'LIS, (from *επι*, and *μηλον*, an apple). See AMAMELIS.

EPIMO'RIOS, (from *επι*, and *μειρω*, to divide). In Galen it is an epithet of the difference of pulse with respect to the inequality of their time in beating.

EPIMULIS, (from *επι*, and *μυλη*, a knee). See PATELLA.

EPINENEUCOS, (from *επι*, and *νευω*, to nod or incline,) an epithet of a pulse which beats unequally in different parts of the artery; also called *perineneucos*. Galen thinks it common in hectic.

EPINE'PHELOS, (from *επι*, and *νεφελη*, a cloud). CLOUDY. An epithet applied to the enæorema in the urine, which appears like a cloud.

EPINO'TION, (from *επι*, and *νωλος*, the back). The SHOULDER BLADE. See SCAPULA.

EPINY'CTIS, (from *επι*, and *νυξ*, night). A pustule which arises in the night resembling a furunculus; according to Sauvages, these are pustules of a blackish-red colour, crowding together, three or four lines in diameter, affecting chiefly the legs, and very frequently painful, chiefly in the night. He enumerates two species:

EPINY'CTIS VULGARIS and PRURIGINOSA. Celsus considers it as malignant, and describes it as of a whitish or somewhat livid colour, with a violent inflammation around it; affecting the hands, arms, and thighs. The ancients rank it with the terminthus, which is rather less; and it is sometimes described as of a dusky red, occasionally of a livid and pale colour, with great inflammation and pain. In a few days it is said to burst, and separate in a slough. When opened, there is an efflux of sanies; a deep ulcer follows, and the pain is more violent than in proportion to its magnitude, for it is scarcely as large as a bean; according to Paulus and Ætius, chiefly troublesome in the night. Celsus recommends that in this, and all other kinds of pustules, the patient walk much, abstain from all acrid food, and be very sparing in his diet. Sauvages recommends bleeding, a cooling diet, antiphlogistic, cathartic, emollient gruels, with the application of cataplasms of mallow flowers, and lintseed.

E'PIOS. MILD, GENTLE. An epithet which Hippocrates bestows on mild epidemic fevers.

EPIPA'CTIS, (from *επιπακτω*, to coagulate; because it coagulates milk). Dioscorides mentions this plant, and Boerhaave thinks it the helleborine latifolia montana of C. Bauhina. *Serapias helleborine* Lin. Sp. Pl. 1344.

EPIPAROXY'SMUS, (from *επι*, and *παροξυσμος*, *paroxysm*), when the patient suffers more exacerbations than usual in a fever.

EPIPA'SMA. See CATAPLASMA.

EPIPA'STON, (from *επι*, and *πασσω*, to sprinkle). See CATAPASMA.

EPIPE'CHYS, (from *επι*, and *πηχυς*, the cubit), the part of the arm above the cubit.

EPIPE'PHYCOS, (from *επι*, and *φωω*, to grow). See ΑΔΝΑΤΑ.

EPIPHENO'MENA, (from *επι*, and *φαινομενον*, a phenomenon or symptom,) adventitious symptoms which do not appear till the disease is formed: the same probably as epiginomena.

EPIPHLE'BOS, (from *επι*, and *φλεψ*, a vein). One whose veins are prominent.

EPIPHLOGI'SMA, (from *επι*, and *φλογιζω*, to inflame). A violent inflammation, attended with pain, tumour, and redness; or internally a burning heat. The shingles of Hippocrates. See ERYSIPELAS.

EPI'PHORA, (from *επιφερω*, to carry with a force). In a medical sense, it is a violent determination, generally inflammatory, of the fluids to any part of the body; but more particularly the flow of tears from the eyes, in consequence of obstructed puncta lachrymalia, imperious nasal duct, or an inflammation of the eyes.

The epiphora, or watery eye, called *rhoeas*, *lippitudo*, *oculus lachrymans*, and MOON EYE, is sometimes confounded with the fistula lachrymalis, for in both the tears run down the cheeks; but in the latter, pus is mixed with the tears. The obstruction in the puncta lachrymalia and nasal duct is sometimes owing to a tumour, as the encanthis in the great angle of the eye; to any accident, as a wound, or burn; to the destruction of the nasal duct; a polypus of the nose; a fistula lachrymalis; an inversion of the eye lid (see ENTROPION); an erosion or other defect of the caruncula lachrymalis.

Dr. Cullen places this disease in the class *locales*, and order *apoceneses*, and defines it a flux of the lachrymal humour. Only one species, the epiphora frigida, can, he thinks, be esteemed idiopathic; and of this there are twelve varieties.

When the cause is a tumour in the angle of the eye, a polypus in the nose, a distortion in the eye lids, and a fistula lachrymalis, it must be removed. When from a conglutination of the puncta lachrymalia, we are to examine whether their ducts are totally obstructed or their mouths only covered; for if after a burn, or from a cicatrix after a wound, a cure is hardly to be expected: but if only a cuticle covers the duct, a perforation may be made with a needle; then a hog's bristle, or silver wire oiled, be passed through, and continued till the part is healed. If from a total want of the caruncula lachrymalis, a cure cannot be effected, because that gland cannot be restored. Mr. Ware thinks it may be occasioned either by a more copious secretion of tears than the puncta lachrymalia are capable of absorbing; or, which is more commonly the cause, by an obstruction in the lachrymal canal. It is the opinion of some anatomists, not only that part of the tears transude through the pores of the conjunctiva and cornea, but that their quantity is increased, and their acrimony abated, by the secretions of the caruncula lachrymalis, and the glandulæ Meibomii. A morbid epiphora is consequently produced by an inflammation in the membranes of the eye, and to be cured by the remedies of inflammation. No such transudation, however, appears to take place. When it originates from an obstruction in the ducts, leading from the puncta lachrymalia into the lachrymal sac, which rarely occurs, the tears fall over the cheeks, and the sac is constantly empty. Pressure therefore on the sac can produce no regurgitation, either of the tears or mucus, into the eye. A probe, of a suitable size, must in that case be introduced through the puncta of the obstructed ducts into the sac; and the operation repeated daily, till the obstruction is removed. The part in which the obstruction most commonly lies is in the sac itself; then the tears, on pressing the sac, mixed sometimes with mucus, flow back into the eye, through the puncture. The causes producing this obstruction to the passage of the tears, are either a thickening of the membrane lining the sac, from previous inflammation;

inspissated mucus lodged in the inferior portion of the cavity, from the same cause; or a spasmodic action of that part called the *sphincter of the sac*.—These three causes sometimes exist together, and mutually increase each other's effect.

Of the various remedies which have been proposed for the cure, Mr. Ware approves most of Monsieur Avel's, recommended first in the year 1712; which consisted in first passing a probe, and afterwards injecting a fluid through the puncta lachrymalia, in order to clear the matter which obstructed the lachrymal passage. Mr. Ware adopted this plan, which in several cases was attended with success. He had a small silver syringe, with pipes fitted to it of various sizes, much shorter than that represented in plate 37, vol. iii. of Bell's Surgery: they were a little arched towards the point, for the convenience of being introduced into the punctum lachrymale with more ease; of these he used the largest that could be introduced without pain, and through it he injected warm water. In introducing the pipe, he found it convenient to stand either behind the patient, or on the side opposite to that of the diseased eye, and always high enough to give him a full command of the patient's head. The syringe being held in the right hand, the eyelid was drawn downward, and a little outward, with the fore finger of the left hand. This brought the inferior punctum fully within the sight of the operator, and placed it in a position very convenient for admitting the point of the pipe. When the pipe was introduced, the finger was removed from the lower lid, and applied as accurately as possible over the superior punctum, to prevent the liquor from escaping through it; and with this finger the lachrymal sac was occasionally compressed, to assist the determination of the liquor downwards to the nose. See Ware on the Epiphora, or Watery Eye; Heister's Surgery; White's Surgery, p. 233; and Dr. Wallis's Nosologia Oculorum.

EPIPHYLLOSPE'RMUS, (from *επι, upon, φυλλον, a leaf, and σπερμα, seed*). Plants whose seeds grow on the back of their leaves.

EPI'PHYSIS, (from *επιφω, to grow to or upon*). *Additamentum*, APPENDIX, is a small bone annexed to the larger by means of an intervening cartilage, only observable in growing subjects, for in adults the epiphysis cannot be distinguished from the bone. Epiphyses are of a larger diameter than the bone they belong to, and serve to render the articulation more firm: the muscles also inserted into them act with greater force, as their axis are further removed from the centre of motion. They are sometimes separated from the head of the bone, and mistaken for a luxation, or a fracture. See SYMPHYSIS.

EPIPLA'SMA, (from *επι, and πλασσω, to spread*). (See CATAPLASMA.) A name for an application of wheat meal, boiled in hydrelæum, to wounds.

EPIPLOCE'LE, (from *επιπλον, the omentum, and κλη, a rupture,*) *hernia omentalis*. A RUPTURE OF THE OMENTUM; or a protrusion of the omentum through apertures in the integuments of the belly. Sometimes, according to Mr. Sharpe, so large a quantity of the omentum hath fallen into the scrotum, that its weight drawing the stomach and bowels downwards hath excited vomiting, inflammation, and symptoms similar to those of the bubonocle. When this hap-

pens, he thinks it necessary to operate as in the bubonocle. The rings of the muscles must be dilated; or the whole cannot be returned. But except inflammation has commenced, this method is not to be attempted.

EPIPLOI'CÆ APPENDI'CULÆ, (from *επιπλον, the omentum*). The peritoneal coat of the intestines sends out some processes like little epiploons, to which Winslow gives this name.

EPIPLOI'CA ARTE'RIA. See SPLENICA ARTERIA.

EPIPLOI'CA DE'XTRA VE'NA is a branch from the trunk of the meseraica major, which goes to the omentum.

EPIPLOI'CA SINI'STRA VE'NA arises from the splenica at the small extremity of the pancreas, and is ramified on the omentum so far as the colon, where it communicates with the hæmorrhoidalis interna.

EPIPLOI'TIS, (from *επιπλον, omentum*). See PERITONITIS OMENTALIS, and PUERPERILIS FEBRIS.

EPIPLOCOMI'STES, (from *επιπλον, the carry, and κομιζω, to carry*). Those who have the omentum in a morbid state; so that it appears, on a comparative view, larger than that of brutes—a circumstance which rarely occurs. It is also applied to those who labour under a rupture of the omentum; but probably it is only a term of raillery.

EPIPLOO'MPHALON, (from *επιπλον, the omentum, and ομφαλος, the navel*). See HERNIA UMBILICALIS.

EPI'PLOON, (from *επιπλω, to run over,*) because it seems to float upon the intestines. See OMENTUM.

EPIPOSCHEOCE'LE, (from *επιπλον, οσχρον, the scrotum, and κλη, a tumour or rupture*). See HERNIA SCROTALIS.

EPIPOLÆ'US, (from *επιπολαζω, to be light*). SLIGHT, GENTLE. Hippocrates applies it to disorders that are not dangerous.

EPIPOLA'SIS, (from *επιπεπολαζω, to swim on the top,*) a REDUNDANCE and FLUCTUATION. In chemistry when what is sublimed ascends only to the surface and there settles, this term is applied.

EPIPORO'MA, (from *επιπαρω, to harden*). An indurated tumour on the joints. See TOPHUS.

EPISARCI'DIUM, (from *επι, and σαρξ, flesh*). See ANASARCA.

EPISCHE'SIS, (from *επισχω, to retain*). See EPISTASIS.

EPI'SCHION, (from *επι, and ισχιον, ischium*). See OSSA PUBIS.

EPISCOPA'LES VALV'ULÆ. Valves resembling a mitre, (from *episcopus*). See COR.

EPISE'ION. See PUBIS OSSA.

EPISEMA'SIA, (from *επι, and σημαιω, to signify*). See ANNOTATIO.

EPISPA'SMOS, (from *επι, and σπασμος*). In Hippocrates it generally means inspiration; but has been supposed to imply a more quick inspiration than usual.

EPISPA'SMOS, (from *επισπλω, to draw*). Medicines which draw the fluids more copiously into the parts to which they are applied, and therefore, strictly, a term of the same meaning as atrahentia; but as the effect of the epispastics is commonly that of exciting blisters, the term is often employed for that of vesicatoria and vesicantia. What the ancients called *epispasticæ* were such external applications as only reddened the skin,

and according to the different degree of effect, received different names; the slightest were called *phænigmoi*, the next *sinapismi*, the more active *vesicatorii*, and the strongest *caustici*. The London college hath changed the name of the blistering plaster from vesicatorium to emplastrum cantharidis. See CATAPLASMA, BLISTERS, and CANTHARIDES.

EPISPA'STICUM MEDICAMENTUM. A dry powder sprinkled on malignant ulcers, to promote a separation.

EPISPHERIA, (from *σφαῖρα*, a sphere). The windings of the exterior substance of the brain; sometimes the circular vessels on its surface.

EPISTAPHYLI'NI, (from *επι*, and *σταφυλινος* a *farsnip*;) from their resemblance to a parsnip. See STAPHYLINI.

EPI'STASIS, (from *επι*, and *στημι*, to stay,) *episthesis*. A suppression of proper excretions; or rather the superfluities of urine, called *insidentia*, opposed to the *upostasis*, *subsidentia*, or sediment in urine. Epistasis is applied in Hippocrates to the beginning and increase of the fit.

EPISTA'XIS, (from *επισταζω*, *instillo*). Hæmorrhage from the nose. See HÆMORRHAGIA.

EPISTO'MION, (from *επι*, and *στομιον*, a mouth). A stopper for a bottle, and a vent-hole of a register furnace.

EPISTROPHÆ'US, (from *επι*, and *στρεφω*, to turn). Epistrophe and epistrophis. The first vertebra of the neck: the same term is applied, though improperly, to the second.

EPITEDEU'MA, (from *επιτηδεω*, to appropriate). The way of living each person adopts. Cælius Aurelianus calls it *vita affectiones*; and Celsus, *vita proposita*.

EPITHE'LIUM, (from *επι*, and *τιθημι*, to cover). See CUTICULA, and PROLARIUM.

EPITHE'MA, (from *επι*, *τιθημι*, and *τιθημι*, to lay upon or apply). A LID or COVER; but used to signify a topical medicine. Epithems are, 1. Liquid; and, when applied warm, called *fomentations* or *embrocations*; 2. Dry or solid; viz. medicated powders folded in cloths, called *sacculus*, and *saccus*; when applied to the head, *cucupha*, and *cucullus*; to the forehead, *frontale*; to the breast or stomach, *scutum* and *pulvinar*; when used as a pillow, *lectulus*; 3. Those of the soft kind, as sinapisms, and poultices. Turner confines the name of *epithem* to liquids in which rags are dipped, to be applied to the parts affected. See Gaubius de Formulæ Medicamentorum.

EPITHE'SIS, (from *επι*, and *τιθημι*, to lay upon). In surgery, it is the straightening of crooked limbs by means of instruments.

EPITHY'MBRUM, (from *επι*, and *θυμβρα*, savory). A species of moss growing on the thymbra, or winter savory.

EPITHY'MUM, (from *επι*, and *θυμον*, thyme). See CUSCUTA.

EPOCHETEU'SIS, (from *εποχαινω*, to drain). A derivation of the juices to other parts.

EPO'MIS, i. e. ACROMION, (from *επι*, and *ωμος*, shoulder). See SCAPULA.

EPO'MPHALUM, (from *επι*, and *ομφαλος*, the navel). Any application to the navel.

EPO'DE, and **EPO'DOS**, (from *επι*, and *ωδη*, a

song, the absurd attempt of curing distempers by incantations.

EPO'SCHION, (from *επι*, and *οσχεον*, a branch). The tendril of a plant.

EPOMPHA'LION, (from *επι*, and *ομφαλος*, the navel,) a medicine supposed to purge when applied to the navel.

EPOSILI'NGA. SCALES OF IRON.

EPSOME'NSIS A'QUA. EPSOM WATER. From this water the bitter purging salt was first procured. Epsom water, which rises near Epsom, in Surrey, differs, at different times, in its solid contents: for, from a gallon Dr. Lister obtained one ounce and a half; Dr. Ruty, one ounce, and in some seasons half the quantity; Dr. Lucas, only five drachms and one scruple. Of this solid matter Dr. Allen alleged that one eighth was an earth, or insoluble matter: but Dr. Ruty found a much less proportion of it; and to him it appeared of a calcareous nature. The salt is mostly a vitriolated magnesia, and probably contains some earth; for Dr. Ruty affirms, that it requires at least twenty-four times its own weight of water entirely to dissolve this salt, though the factitious Epsom salt dissolves readily in little more than an equal weight of water.

EPSOME'NSIS SAL. See CATHARTICUS SAL.

EPU'LIS, (from *επι*, *υιον*, and *ουλα*, the gums). Vogel describes it, "a tubercle on the gums without inflammation."—Of these there are two species; one without pain, the other troublesome, and often degenerating into a cancer; some have a broad basis, and others a slender neck, by which they are united to the gums.

The best method of cure is totally to extirpate them. When they have a small neck, or root, they may be separated by a thread; but when the basis is broad, it may be destroyed with the aqua kali, or a solution of sal ammoniac. If these mild corrosives fail, it is better to use the knife than to employ the stronger ones.

After the tumour is extirpated, the mouth should be washed with red wine, or oxybate with alum; and when the blood ceases to flow, the honey of roses may be applied. See Turner's Surgery, vol. i. p. 210. Heister's Surgery.

EPULO'TICA, (from *επι*, and *ουλη*, a cicatrix; *επουλωω*, is to cicatrise). EPULOTIC. *Cicatrifiantia*; *desiccativa*; *apulotica*; topical medicines which absorb moisture, repress fungous flesh, and dispose wounds or ulcers to heal. Dry lint, a gentle compress, and the cerate, with lapis calaminaris, are the general applications. Dr. Cullen thinks it is extremely doubtful if any medicine exists which can induce new skin on a wound: the propriety of the term, therefore, may be justly questioned.

E'QUI CLI'BANUS. In chemistry it is the heat of horse dung.

EQUI'NA FRA'SA. See FABA MINOR.

EQUISETUM, (from *equus*, a horse, and *seta*, a hair). *Cauda equina*, HORSE TAIL. *Hispuris vulgaris* Lin. Sp. Pl. 6. It has been recommended as an astringent in diarrhoeas and hæmorrhages; but is now little used.

E'QUI VENTER. See VENTER.

EQUITA'TIO, (from *equito*, to ride). RIDING. When the bowels are empty, they are powerfully strengthened by this species of exercise. Its use arises from the repeated gentle agitation given to these parts,

calculated to remove visceral obstructions, promote the circulation of the blood, determine the fluids to the surface of the body, and increase perspiration. Dr. Huxham had so high an opinion of this remedy, that he says, where medicine has failed, in some chronic diseases, riding only has performed a cure: when a patient can therefore sit on horseback, he recommends the daily use of this exercise. See *ÆORA*.

E'RAWAY. See CATAPUTIA.

EREBI'NTHUS. See CICER.

ERECTIU'SCULUS, (a dim. of *erectus*). In botany, it means erected, or lifted up a little.

ERE'CTOR CLITO'RIDIS, (from *erigo*, to lift up). See CLITORIDIS MUSCULUS.

ERECTO'RES PENIS. These muscles, arising from the inside of the tuberosity of the ischium, are lost in the crura, where they unite. They are also called *directores penis*; and Spigelius calls them *collaterales penis*, from their collateral order of fibres.

ERE'GMOS, (from *ήρησμις*, to break). It is any leguminous fruit decorticated and broken into pieces. Fœsius thinks it is bean meal.

ERETHI'SMOS, (from *ερεθίζω*, to excite, irritate). In general, medicinally used, it signifies every thing irritating, comprehending whatever weakens the vires vitæ, and thus destroys the vital heat; or impedes critical efforts, from hence styled *σημεία ερεθιστικά*, *signa irritantia*. In particular, it signifies an irritation of the belly, from thin acrimonious humours, and their discharge in liquid stools. Some modern authors give this appellation to a fatal disease of the apoplectic kind, which sometimes occurs during a mercurial course.

ERE'TRIA TE'RRÆ, (from *Eretria*, the place from whence it was brought). ERETRIAN EARTH, styled *canabil*. It is a peculiar alkaline bole; once much used as an astringent and sudorific. Dioscorides and Galen describe two kinds, white and grey: the latter was in the highest estimation. The ancient esteemed it an useful medicine, and were very careful in their mode of preparing it, by frequent washing. Though unknown to the present practice, some think it may, from its alkaline quality, be still useful. It is dug up in the Negropont, near ancient Eretria, where it might be readily procured.

EREÚ'GMOS, and EREUXIS, (from *ερευω*, to eructate). AN ERUCTION.

EREÚ'MENA U'RA. Urine that assumes a cloudy consistence in the middle.

ERGA'SIMA. See MYRRHA.

ERGASTE'RIMUM, (from *εργον*, a work). A LABORATORY. In particular, it is that part of a furnace in which the cupel, alembic, or retort, containing the matter to be acted on, is placed.

E'RGOT. So the French call a disease, which resembles one in England, caused by eating bad corn. It consists of extreme debility, with mortification of the extremities, partly from the unalimentary nature of the substance; but more probably from the effect of some animalcule, for which the injured grain (generally rye) affords a nidus. The name is derived from the resemblance of the diseased corn to a cock's spur.

ERI'CA, (from *ερεϊνω*, to break; so called because it is broken to make besoms of). ERICE, COMMON HEATH, HEATHER, LING. The flower is of a curious structure,

and a decoction of the plant is recommended as a solvent for the stone; five ounces of it are to be drunk every night and morning. See Raii Hist. It is the *erica vulgaris* Lin. Sp. Pl. 501.

ERICE'RUM. The name of several collyria in *Ætius*, so called from *erica*, *heath*, which is an ingredient.

ERI'GERUM, (from *ήρ*, the spring, and *γερων*, old; because in spring it has a white blossom, like the hair of an old man). *Simpson*, and *groundsel*, called also, by *Myrepsus*, *cortalon*. It is a low plant, and too generally known to require a description. The species used in medicine, the *senecio vulgaris* Lin. Sp. Pl. 1216, is an annual plant; but may be found at all times of the year. The expressed juice of the leaves, or an infusion of them, is a powerful emetic and cathartic. A tea cupful of the juice will operate with maniacs as an emetic when other means fail, and thus slight attacks of the disorder may be removed. See Lewis's *Materia Medica*; and for its singular power externally applied, *Edinburgh Medical Essays*, vol. ii. art. 5.

ERI'NEAS. See FICUS SATIVA.

E'RIX. See JECUR.

ERIZA'MBA. See ASPHODELUS LUTEUS.

ERODE'NTIA, (from *erodo*, to eat away). See ESCHAROTICA.

ERODI'NIUM. See PROGNOSIS.

ERO'SUS, (from *erodo*, to eat away). In botany it means notched at the edges, as if gnawed or eaten.

ERO'TION, (from *ερωω*, to love; because bees are fond of it). See MELISSA.

EROTOMA'NIA, (from *ερωω*, love, and *μανια*, madness). That sort of melancholy arising from disappointed love, or anxiety from delay. See MELANCHOLIA.

ERO'TYLUS, (from *ερωω*, love). A species of fungus resembling *erodium*. See CORALLOIDES FUNGUS.

ERRA'NA, ERRA'TICA, (from *erro*, to deviate). ERRATIC FEVERS, IRREGULAR TERTIANS OR QUARTANS. See INTERMITTENS.

ERRHI'NA, (from *ήρ*, the nose). *Sternutatoria*. ERRHINES, called *nasal*, *caput furgia*, which last is a barbarous term, implying those remedies which purge the head. These are either *errhines*, or *masticatories*: the former is the term given by Galen to *sternutatories*; substances which, if snuffed up the nose, promote a discharge of mucus from that organ. At present the milder sorts are distinguished by the name of *errhines*, and the stronger by that of *sternutatories*, because they excite a sneezing. Besides the general shock that sneezing gives to the whole body, it tends to remove remote obstruction; so as to be useful in lethargies, epilepsies, palsies, apoplexies, head aches, vertigos, catarrhs, gutta serena, &c. The action of sneezing seems to be more extensively useful by its general shock than that of vomiting; but it should be observed, that if there is any kind of plethora in the habit, *sternutatories* are dangerous. There seems little distinction in the different articles which compose this class, except in their violence. The betony, the sweet marjoram, the orris root, and rosemary tops, are of the milder kind: the *asarum*, *euphorbium*, the tobacco, the white hellebore, and the turbith mineral, of the latter. The more acrid are chiefly evacuants. The use of *errhines* is now very limited, and principally confined to inflammatory obstruc-

tions in the nose, and to gutta serena. The agitation they produce does not extend beyond the head. See Cullen's *Materia Medica*.

ERRI'PSIS, (from *ἔρπω*, to precipitate). When spoken with respect to the body, it signifies a loss of strength.

E'RROR LO'CI, (from *erro*, to deviate). Boerhaave introduced this term, from the opinion that the vessels were of different sizes for the circulation of blood, serum, and lymph; and that when the larger sized globules were forced into the lesser vessels by an error of place, they were obstructed. This opinion is, however, no longer adopted, as it originated from microscopical observations, in which the conclusions were too hastily drawn.

ERU'CA, (from *erugo*, to make smooth; from the smoothness of its leaves). ROCKET; *euzomon*. It resembles mustard in appearance, but is distinguished by the smoothness of the leaves, and its disagreeable smell. The seeds have a pungent taste, somewhat like that of mustard, but weaker. The sort used in medicine is the *brassica eruca* Lin. Sp. Pl. 923. It is also a term for mustard. See SINAPI.

ERU'CA SATI'VA, called also *eruca latifolia alba*, *eruca major sativa*. GARDEN ROCKET; *brassica eruca* Lin. Sp. Pl. 923. The roots have a hot biting taste, and the seeds have the same qualities. The herb is eaten as a salad, and is somewhat warm and diuretic; but is not in use as a medicine.

ERU'CA SYLVE'STRIS, called also *eruca sylvestris major*, and *eruca tenuifolia*, *brassica erucastrum* Lin. Sp. Pl. 923. WILD ROCKET.

ERU'CA SI'LIIQA CAULI OPPRESSA. HEDGE MUSTARD. See ERYSIMUM.

ERUTHE'MATA, (from *ερυθμα*, to make red). RED FIERY TUMOURS which arise from inflammation, as in erysipelas.

E'RVA DE SA'NCTA MARI'A. See DRACONTIUM.

ERVILIA, (dim. from *ervum*, vetch). See OEHRUS.

E'RVUM, (quasi *arvum*, a field; because it grows wild in the fields,) *orobus*, *crobychis peregrina*. The BITTER VETCH; *ervum ervilia* Lin. This plant grows two feet in height: its leaves and flowers are like those of the tare in their shape, but are less, and of a white colour; they are succeeded by pods which contain two or three large, round, whitish seeds. It is a native of France, Italy, and the warmer parts of Europe. The seeds have a farinaceous, disagreeable, bitter taste; are supposed nephritic, powerfully diuretic, and, if mixed with honey, expectorant.

E'RVUM LENS. See LENS.

ERYNGIUM, (from *ερυγγανα*, to eructate; because it causes eructations). ERYNGO. *Eringus*, *eryngium maritimum*, *inguinalis*, *atherea herba*, *aster atticus*, *hyophthalmos*, *crocodilion*, *iringus*, and SEA HOLLY, *eryngium campestre* Lin. Gen. Pl. 337; supposed to be the *ερυγγιον* of Dioscorides, who with other ancient writers, speak highly of its efficacy.

The *eryngium maritimum* Lin. Sp. Pl. 337, does not differ in quality or power. It is a bluish branched plant, with mallow-like, thick, prickly leaves, angular or jagged about the edges; the flowers are white; the roots slender and long, brown on the outside, and

white within. It is perennial, growing plentifully on some of our sandy and gravelly shores; and flowers in July.

The root has an agreeable sweet taste, which on chewing is followed by a light aromatic pungency. Freely used, it is aperient, diuretic, and antiscorbutic. It has been extolled as an aphrodisiac; but it is now very seldom used except as a comfekt.

The candied roots, bought at the confectioners, are ingredients in artificial asses' milk, which is thus made:

Take of candied eryngo root one ounce; pearl barley, half an ounce; liquorice root, three drachms; boil them in two pints of water to one pint, to which add a pint of new milk from the cow; boil them gently together, and strain the decoction. Half a pint should be drunk three times a day.

ERYNGIUM FÆTIDUM, Lin. Sp. Pl. 336, is highly esteemed in America as an antihysterical medicine; and in large doses is said to act powerfully as a cathartic and a diuretic. It is chiefly employed in the hysteria and dropsy.

ERY'SIMUM, (from *ερωω*, to draw; from its power of drawing blisters). *Iris*, *camelina*, *chamæpilion*, *verbena femina*, *eruca siliqua caulis oppressa*. HEDGE MUSTARD. *Erysimum officinale* Lin. Sp. Pl. 922.

It is a hairy plant, with oblong narrow leaves, tough branched stalks; bearing numerous small yellow flowers; followed by short roundish pods, full of small reddish brown seeds. It is annual, common in waste places, and flowers in July.

This plant is not in much esteem: it has been employed in the cure of hoarseness like the horse radish (see RAPHANUS RUSTICANUS); and perhaps, as having less acrimony than the other siliquose plants, it may be more frequently used. Cullen's *Materia Medica*. The leaves are herbaceous to the taste; the flowers attenuant, expectorant, and diuretic; the seeds resemble in their qualities those of mustard, but are much weaker: their acrimony is extracted totally by water, and partially by spirit. Water is strongly impregnated with them in distillation. Stahl highly commends the active parts of this plant in scirrhus-cancerous tumours. It is also a name of the sophia.

ERY'SIMUM ALLI'A'RIA. See ALLIARIA.

ERY'SIMUM BARBAREA. See BARBAREA.

ERY'SIMUM LATIFO'LIIUM, also called *sinapi sylvestre*, &c. BROAD LEAVED HEDGE MUSTARD. Its virtues are similar to those of the other kind. Raii Hist.

ERY'SIMUM THEOPHRA'STI. See FAGOPYRUM.

ERYSI'PELAS, (from *ερωω*, to draw, and *πelas*, near; because the neighbouring parts are affected by the eruption; or from *ερυθρος*, red, and *μελας*, black, a dark red). *Antonii sancti ignis*; *ignis sacer*; *brunus*; *herpes ferus*; *ignis Persicus*; *επιφλογιστη*; *zoster*, *zona*, *macula lata*; the GIRDLE; SHINGLES; in Switzerland, the VIOLET; in this country, the ROSE; by Galen and Celsus, PHYGETHLON; commonly in English, SAINT ANTHONY'S FIRE.

Dr. Cullen places this disease in the class *pyrexia*, and order *exanthemata*; which he defines an inflammatory fever of two or three days, attended commonly with sleepiness, often with delirium. In some parts of

the skin, most frequently on the face, there is an erythematous inflammation. (See PHLOGOSIS ERYTHEMA.) He distinguishes two species:

1. ERSI'PELAS VESICULOSUM; an ERYTHEMA, with a spreading redness occupying a broad space, which in some parts runs into large blisters; comprehending the *e. rosa*; *typhodes*; *pestilens*; *contagiosum*; and *febris erysipelatosæ* of Sydenham.

2. ERSI'PELAS PHLYCTENODES; an ERYTHEMA, consisting of many pimples occupying particular parts of the trunk of the body, and running quickly into phlyctenæ, or small blisters. This comprehends the *e. zoster*; *e. zona*; SHINGLES; *zona ignea* of Hoffman; *herpes zoster*. When symptomatic it is the *e. ex veneno*. The term erysipelas has been applied by medical writers to the erythematous inflammation, as well as the erysipelatosæ fever; but Sauvages properly uses the term vitium cutaneum, because, where only a symptomatic fever attends, he calls it *erythema*; and *erysipelas* when exanthematic fever precedes.

This disorder may affect any part of the body; but the face is most frequently its seat; next the arms, the body, and then the feet. The seat of the true species is in the surface of the skin; Heister says in the scarf-skin and the internal membranes.

It most frequently happens in autumn, or in any season when hot weather is succeeded by cold and wet. The sanguine and plethoric, young people, and pregnant women, are most subject to it: those who have once been affected are very liable to future attacks.

The causes are chiefly sudden cold succeeding a great heat or sweat, obstructed perspiration, and an acrimonious blood. Tissot attributes it to two causes; 1st, An acrid humour, commonly bilious, diffused through the mass of blood; and this was the opinion of Hippocrates and Galen. 2dly, The humours not being duly discharged by perspiration.

The symptoms of this disease are well described by Tissot. It begins with a violent shivering, succeeded by a burning heat, a violent headach, and sickness, that continue till the erysipelas appears, which happens only on the second or third day: the fever and sickness then abate; though frequently a small degree of both remains during the increase of the disease. When the inflammation is in the face, the headach continues until the decline of the eruption; the eye lids swell, and the eyes close. It often passes from one cheek to the other, and extends successively over the forehead, neck, and nape of the neck, when the disease is of unusual duration. Sometimes also, when in a high degree, the fever continues, the brain is oppressed, the patient is delirious, and in great danger. A violent erysipelas in the neck brings on a severe and often fatal angina. When it attacks the leg, the whole limb is swelled, and the heat and irritation from it extend up to the thigh. Whenever the tumour is considerable, the part it seizes is covered with small pustules, filled with a clear watery humour, resembling those which appear after a burn: these afterwards dry and scale off. Sometimes, when erysipelas affects the face, the fluid from the pustules is glutinous, and forms a thick scurf nearly resembling those of sucking children, and they continue on the face many days. When the disease is violent, it continues eight, ten, or twelve days, at the same

height; and is at last terminated by a very plentiful sweat, that may sometimes be predicted by a restlessness, attended with shivering, and a little anxiety of some hours duration. In the progress of the disease, the whole skin, and even the inside of the mouth, are very dry.

An erysipelas rarely comes in this climate to suppuration; when it does, the suppuration is always unkindly, and much disposed to degenerate into an ulcer. But in the colder countries, and even in Scotland, a phlegmonous inflammation, with proper pus, often comes on in different points. Sometimes a malignant species of erysipelas is epidemical, and then it frequently terminates in a gangrene. The eruption often retires suddenly; and the patient is disordered with a propensity to vomit, a sensible anxiety and heat; the erysipelas appears again in a different part, and he feels himself relieved. But if, instead of re-appearing on the surface, the humour is thrown upon the brain, or the breast, he dies within a few hours; and these fatal changes and translations sometimes occur without the least reason for ascribing them either to any error of the patient, or his physician. If the humours have been transferred to the brain, the patient immediately becomes delirious, with a highly flushed visage, and very quick sparkling eyes; soon after he becomes delirious, and dies lethargic. When the head, however, is affected, it is not always that the external inflammation recedes: more frequently the violence of the determination is such that the internal as well as the external carotids take their share, and the brain as well as the skin suffers. The lungs are more seldom attacked, and generally from a recession of the external inflammation. The anxiety and heat are then violent. There are some constitutions subject to a very frequent, and, as it were, an habitual erysipelas: if it often affects the face, it is generally repeated on the same side, and that eye is at length considerably weakened.

Sydenham reckons the ESSERA (which see) among species of erysipelas.

Erysipelas should be distinguished from the plague, and from inflammations of different kinds that appear on the skin.

When erysipelas approaches suddenly, but with little disturbance, and attacks a person with a good habit; and when no important parts are affected, there is little danger. Sometimes a convulsive disease, as an asthma, or colic, hath been relieved by the approach of erysipelas externally. Danger is very considerable when this disorder is deeply seated, fixed on the brain or lungs, and the habit of body weak; in some debilitated constitutions this disorder leaves a swelling in the foot or ankle, both troublesome and difficult to remove. By bad management it is easily and soon rendered fatal; and frequent returns denote a disordered liver or gall bladder: when seated in the face, and drowsiness attends it, there is danger of a phrenitis, or of a lethargy: when it seizes the breast, particularly of women in child bed, or who give suck, an abscess is often the consequence: if the nostrils and mouth are dry, and the patient is drowsy, an inflammation of the brain of a similar kind is to be suspected. It is generally fatal within the seventh day; and to those who are often seized with this disease it at last proves fatal.

The causes of erysipelas are the same with those of all febrile cutaneous complaints, an acrimonious discharge, stopped by the cuticle, and exciting inflammation on the skin. The matter is, however, in a larger quantity, and seemingly more fluid than the virus of any other exanthema. It flows with considerable rapidity, very copiously between the cuticle and cutis, elevating the former, and occasionally arising in pustules. At the same time, it is not naturally of a kind to excite active inflammation; but is rather the effect of diminished power of the vessels, for it is a disease to which persons who have lived long in a warm climate are peculiarly subject. It is owing to the effusion of a fluid similar to that thrown out when the tone of the vessels has been destroyed by violent previous excitements, as in burns, from continued cold, as in chilblains, or from the application of sedative poisons. It sometimes, indeed, in cold regions and inflammatory constitutions, suppurates properly; but more often produces a foul ulcer, with tendency to gangrene. We have four times seen it epidemic; and more than once we have had reason to suspect that it was communicated by infection.

It sometimes appears in a more chronic form, and often returns at regular periods in broken constitutions. It does not then appear to be a salutary deposition, though it has not been thought expedient to prevent its recurrence. To support the strength and regulate the state of the perspiration, are the best means of at least avoiding considerable danger from it.

In erysipelas the diet should be mild: roasted apples may be eaten freely; the drink may be whey, barley water, small beer, water gruel, or, if the pulse sinks, small negus may be allowed. The patient should keep out of the bed during some hours in the day; and equal care should be taken to guard against the extremes of heat and cold. In the slighter cases, perspiration may be kept up with frequent draughts of camomile or of elder flower tea, acidulated with the spiritus febrifugus of Clutton, or with other cooling diaphoretics. If the face and head be affected, gentle but repeated purging is useful, and it should be continued until all danger seems to be alleviated. But if the pulse is strong and hard, the patient may be bled, and this evacuation repeated as the fever and his strength indicate. Whenever the head is much affected, numerous and repeated blisters must be applied: we have found four large ones scarcely sufficient to deplete the vessels of the brain. The bowels may be kept soluble by means of cream of tartar, whey, tamarinds, &c. Dr. Freind observes, that when the head is affected, purges are the best remedies, and they undoubtedly are so; but it should be added, that sinapisms may be also applied with singular advantage to the soles of the feet.

When the external inflammation recedes, the disease must be treated as an internal inflammation of the part affected, not of the active kind; for when the pulse is low, cordials and the warmer perspiratives are necessary; and wine often an essential remedy.

From the nature of this disease, and from the peculiarities in the skins of different persons, much caution is required in the application of external remedies. When the scarf skin is raised in blisters, and the serum begins to transude, absorbing powders, such as chalk finely

powdered, or fine flour, may be sprinkled slightly over the inflamed part. In every period of the disease some fluid exudes, and these applications are useful. Watery fluids are injurious, and saturnine applications, unless used with prudence and caution, dangerous; yet Goulard's solution has been sometimes, it is said, employed with advantage.

The symptoms of a suppuration will sometimes come on, but this process should be by no means encouraged. The abscess will be deep, foul, and difficult to heal.

If a gangrene is threatened, besides the inward use of camphor and the bark, spirituous and astringent applications should be employed externally, such as mixtures of lime water with camphorated spirit, or camphorated spirit mixed with tincture of myrrh, or an infusion of the bark.

Erysipelas is sometimes of the nervous or low kind; appearing with a puffy redness in the skin instead of a swelling; the pain is more acute, but the throbbing of the vessels less; no circumscribed tumours appear, but the parts are more inflamed: at the decline of the disease, the redness of skin becomes of a purple hue; it is very liable to terminate in a mortification; the habit from the first, and throughout, is very irritable, and the strength depressed. It is generally accompanied with neuralgia, itching, inflammation of the skin, painful ulcerations, and small lucid pustules.

In some strong habits, both a phlegmonous and the low erysipelatous inflammation attend together; in which case, a moderate evacuation of blood may be allowed, but should be cautiously attempted. If the patient labours under great depression of strength, irritability, &c. we must support his strength with wine, and the warmest cordials; when blisters arise, the bark may be freely given, from \mathfrak{z} vi. to \mathfrak{z} i. or more if the stomach will bear it, in twenty-four hours. When the eruption is apparently complete and the pustules ripened, snip the blisters, and absorb the fluid with soft rag; then apply the unguent. spermatis ceti, or ung. lapidis calaminaris. See Sydenham; Heister's Institutions of Surgery, p. i. lib. iv. c. vi. p. 290; Cullen's First Lines, edit. 4. vol. ii.; Kirkland's Medical Surgery, vol. i. p. 329, 404; Pearson's Principles of Surgery, vol. i. p. 173; and White's Surgery, p. 12.

ERYSIPELAS BULLA'TUM, and INFLAMMATO'RIMUM. See OEDEMA ERYSIPELATOIDES.

ERYSIPELAS CU'RANS A'RBOR. See MALLEAMOTHE.

ERYSIPELAS INFANT'ILIS. Erysipelas of infants was first noticed by Dr. Underwood, who calls it *anomalous inflammation*; though he speaks of infants being liable to erysipelatous inflammation.

It never appears after the month, but most frequently shows itself a few days after birth; and children are sometimes born with it: in a few instances it is preceded by jaundice or a locked jaw. It attacks suddenly the most robust as well as delicate children, and its progress is rapid; the skin turns of a purplish hue, and soon becomes very hard.

The milder species appears often on the fingers and hands, or the feet and ankles, and sometimes upon or near the joints, suppurating quickly. The more violent kind is almost always seated about the pubes, extending upwards on the belly, and down the thighs and legs;

though it sometimes begins in the neck. The swelling is moderate; but after becoming hard, the parts turn purple, and very often sphacelate; especially in boys, when it falls on the scrotum. The penis then swells, and the prepuce appears emphysematous as in children when a stone sticks in the urethra.

Osiander seems to connect it with the epidemic constitution; and remarks, that when it appeared, puerperal fevers of a bilious or rheumatic kind were common. The danger is less in proportion to the extent of the inflammation.

Various means have been used with little success; though for a time benefit was apparently received from saturnine fomentations and poultices, applied on the very first appearance of the inflammation: but it soon spread, and a gangrene came on. When matter is formed, the tender infant soon sinks under the discharge. The bark, with a small portion of the confectio aromatica, sometimes succeeds. Dr. Garthshore has recommended the application of linen compresses wrung out of camphorated spirit of wine, in the place of the vegeto-mineral water, which has proved successful in some instances; though the greatest number of infants, attacked with this disorder, still sink under its violence, and many of them in a very few days.

Professor Hufeland recommends evacuating the alimentary canal and stomach, giving afterwards diaphoretics and antispasmodics, particularly valerian and the calx of zinc. Bark and camphor he only advises when mortification threatens; and saturnine applications are, he thinks, dangerous. See Underwood on the Diseases of Children; Bromfield in the Medical Commentaries; Osiander's Essays on Physic and Midwifery; Hufeland's Observations on the Erysipelas of new born Children; and Gertanner's Memoir.

ERYSIPELAS PULMONIS LO'MMII. See INFLAMMATIO CORDIS.

ERYSIPELATOIDES, from *erysipelas*, and *ειδος*, (*likeness*;) a tumor resembling the erysipelas, or a spurious erysipelas. See ŒDEMA ERYSIPELATOIDES.

ERYSISCEPTRUM, (from *ερυθρος*, *red*, and *σκηπτρον*, *sceptrum*;) from its colour and resemblance to a sceptre). See ASPALATHUS.

ERYTHE'MA, (from *ερυθος*, *red*). See INFLAMMATIO.

ERYTHE'MA A FRI'GORE. See PERNIO.

ERYTHE'MA AMBU'STIO; the inflammation caused by burns or scalds. See COMBUSTURA.

ERYTHE'MA GANGRENO'SUM. See CARBUNCULUS.

ERYTHRION, (from *ερυθρος*, *red*). The name of an amalgama in P. Egineta.

ERYTHRO'DANUM, (the same, from the colour of its juice). See RUBIA TINCTORUM.

ERITHROEIDES, (the same, and *ειδος*, *form*;) from its red colour). See TESTES.

ERYTHRO'XYLON, (the same, and *ξυλον*, *wood*). See CAMPECHIENSE LIGNUM.

E'SAPHE, (from *εσαφαω*, *to feel with the fingers*). The touch or feeling the mouth of the womb, to ascertain its state.

ESCAPA'TLI. A species of senna.

E'SCHARA, vel E'SCURA. An ESCHAR or CRUST. In surgery it is a hard crust, or a scab upon the flesh, formed by the application of a red-hot iron, a caustic, or some sharp humour. Also a slough, formed on a

wound or ulcer, and is a symptom of mortification. Likewise the name of a sub-marine plant which resembles a net or cobweb, called *frondiphora*; *porus reticulatus*; the habitation of a polypus, dilated in membranous expansions, porous internally, and each surface furnished with pores disposed in a quincunx. Linnæus has united it with the millepores, and with reason, for the animals appear to be similar. Ellis has confounded the escharæ by uniting with them the flustra. Their virtues are similar to those of coral, but it is not known in practice.

ESCHAROPE'PA. In Hippocrates it is a term for roasted barley meal.

ESCHARO'TICA, (from *εσχαραω*, *to bring on crusts by burning*, ultimately from *χαιω*, *uro*). ESCHAROTICS, called also *erodentia*, *caustica*, *cauteria*. Substances which dissolve the solid matter of the human body, or attract its moisture. They are used where either a portion of the solid matter is to be taken away, or its texture to be so destroyed that it may fall off, or be easily separated from the other parts.

CAU'STICA, (from *καω*, *uro*, *to burn*;) *caustics*, and *escharotics* differ only in degree, for both destroy the part to which they are applied. Van Helmont first asserted their inefficacy on dead bodies: and Dr. Petit of Paris confirmed it. These kind of applications deprive the part of life, either by their attraction for moisture, which destroys the organization, or by excess of excitement. The dead portion is then separated by the vital power; and what surgeons call the *slough*, or *eschar*, is separated.

Caustics, or cauteries—for they do not differ—are distinguished into actual and potential. The actual is real fire, or a red-hot iron; but these, on account of the terror and pain they occasion, are laid aside. The potential are those which act in the manner already explained. The chief of these are what were called *causticum lunare*; *commune fortius*, or *lapis infernalis*; *antimoniale*: now named *argentum nitratum*; *calx è kali puro*; *antimonium muriatum*.

Their use, besides that of destroying excrescences, or morbid parts, is to open large abscesses where there is danger of cutting some adjacent vessel, or when the knife terrifies the patient. In this case the common milder caustic is generally sufficient, and may be thus applied: lay a piece of sticking plaster on the soft part of the abscess, having previously cut a hole in it, nearly as big as the eschar is to be made; on the hole of the plaster lay the caustic, which must be secured by another piece of sticking plaster. When the skin is not inflamed, the caustic very often occasions little or no pain; and when the eschar separates, or is so loose as to be easily removed, the purulent matter is discharged. When issues are made by caustics, or bones laid bare by them, the eschar must be cut out immediately, or very soon, lest new flesh should fill up the part which is opened. To lay a bone bare, or to make an issue, let the caustic continue on the part about four hours; to destroy a large gland, six; but to open an abscess it may remain two or three hours, according to the thickness of the skin; though generally, when the effect of the caustic is completed, the part on which it is applied ceases to be uneasy.

When a large fungus is to be destroyed by a caustic, the method described by Dr. Barry in the Edinburgh

Medical Essays seems most eligible. The lapis infernalis was applied to a tumour on the coats of the testis; after the separation of the eschar, the lapis infernalis and oleum vitrioli were alternately rubbed on the part; the one instantly removing the pain occasioned by the other: at each dressing, this alternate application was repeated, till the intended effect was produced: the moisture was then absorbed by an armed probe, and a digestive applied. This method prevents the continuance of pain, and is not productive of any degree of inflammation; it is also recommended for the removal of scirrhus, or any other tumour that admits of a caustic; but it very often fails.

Mr. John Hunter recommends a mixture of opium with caustics, in order to lessen the pain which they occasion: this plan generally succeeds, though a much longer time is necessary. See CAUSTICUM OPIATUM.

A great inconvenience in the application of caustics is their spreading, when applied, beyond their limits. The solid form of the argentum nitratum is in this way very convenient. Applications which destroy tender fungous flesh are of this kind, as the vitriolated copper, the red oxides of mercury, and alum, so far calcined as to separate its water and concentrate its acid. All the mineral acids are caustics; but seldom used on account of their great fluidity. See White's Surgery, p. 188.

E'SCARPE. See FASCIA.

E'SCHEL; an imperfect zaffer. See COBALTUM.

ESCULENT, (from *εσχω*, *eatable*,) an epithet applied to plants and roots.

E'SCULUS, (from *εσχω*, *to eat*; because its acorn is eatable). A species of oak. *Quercus esculus* Lin. Sp. Pl. 1414.

E'SDRE ANTI'DOTUS. An antidote described by P. Ægineta.

E'SEBON. See MARINUM SAL.

ESO'CHE, (from *εσω*, *within*, and *εχω*, *to have*). A tubercle within the anus.

ESOX LUCIUS. The PIKE. From the liver of this fish an acrid oil spontaneously separates; used in Germany to take spots from the transparent cornea, or as a stimulating application in rheumatism.

E'SPHILASIS, (from *εσφλασμα*, *to recede inwards*). A recession of a part inwards from some violent outward impression.

ESSA'TUM, (from *esse*, *to be*). The power or principle which is inseparable from any substance.

ESSA'TUM POTENTIA'LE. The medicinal power or virtue which resides in vegetables and minerals.

ESSA'TUM VI'NUM. Spirit of wine impregnated with the medicinal virtues of vegetables.

ESSE'NTIA, (from *esse*, *to be*). ESSENCE. From philosophy this word has been transferred to chemistry, where it seems strictly to import the distinguishing part of vegetables or minerals. In the former it consists generally of the essential oil; but no peculiar principle in the latter merits this title.

ESSE'NTIA ABIE'TIS. See ABIES.

ESSE'NTIA NERO'LI. See AURANTIUM.

ESSENTIA'LE SAL. See DIURETICUS SAL.

ESSENTIA'LIS, (from *esse*, *to be*). ESSENTIAL. It is an epithet for salts procured from vegetable juices, by crystallization. For the process, see ACEROSA. When the viscous juices of vegetables are

used in this process, the salt cannot be obtained without a previous fermentation to dissolve their tenacity. Juices that contain an oil or a balsam will not easily yield their salt, for oils and balsams prevent its crystallization. These salts are not alkaline; but become such by burning.

The oils peculiar to different vegetables are also called *essential*; and are generally the volatile, containing the peculiar smell and taste of the plant.

Some fevers are called *essential* or *idiopathic*, to distinguish them from the symptomatic.

ESSENTIA'LIS SAL. ESSENTIAL SALT. This name is given to all concrete saline substances, which preserve the principal qualities of the vegetable and animal bodies from which they were obtained. The usual method of preparing is by evaporating, to nearly the consistency of a syrup, the liquors containing them. The crystals which shoot from these liquors may be depurated by dissolving them in water, filtering, evaporating, and crystallizing.

Very often the salts thus obtained from animal and vegetable matters are only vitriolated tartar, vitriolated natron, nitre, common salt, and similar neutral salts, which only merit the name of essential salts when intimately combined with the peculiar oil of the plant.

E'SSERA, (from the Arabic *sorah*). The CHRONIC NETTLE RASH. It is called *essere*, *sora*, and *sara*, by the Arabians; by Sydenham, a BASTARD or SCORBUTIC ERYSIPELAS, with or without ulcerations; the NETTLE SPRING, from its resemblance to the eruptions excited by the stinging of nettles. This appears to be a disease which Pliny calls *zoster*, and some others *zona*. Dr. Cullen observes, that the nettle rash of the English is considered as the urticaria; but the disease described by Dr. Heberden in the London Medical Transactions, which Cullen hath often seen, is totally different from the urticaria of nosologists, as it is chronic without fever, and may be associated with the impetiginous. The chief distinction consists in the hardness felt in the skin.

The essera is a species of tumour not mentioned by the Greeks nor Latins. It is truly a chronic disorder, and is seated in the cutis. Some persons are affected with it only when the weather is frosty, others chiefly in the hottest months. Persons of all ages and of both sexes are subject to it. Sennertus attributes the disease to the serum; Dr. Heberden to an acrimony not unlike the fish poison, as the diseases are nearly the same.

This disorder appears in the skin in the form of small white hard tubercles, generally with a dark irritable point; sometimes these are broad and long, such as appear after being lashed with a whip; an intolerable itching attends; and generally the skin is inflamed in the spaces between the eruptions. The elevations appear suddenly: they seldom continue long; but disappear and appear again in another part. When many of the tubercles appear together, the part seems swelled. In some instances this disorder totally disappears in a few days, in others it hath continued some months, and even years, disappearing at times, but returning after very short intervals. For the most part the itching is the only inconvenience; and this indeed is sometimes so great as to deprive the patient of sleep; but sickness, headach, or other troublesome symptoms

sometimes come on during the presence of the eruptions; at others on their suddenly sinking in. We have found headach, &c. supervene on bathing them with cold water, when they were very numerous and highly inflamed. They have been attributed to the bites of insects; and we think we have found, that those who wear boots are less subject to them in the legs.

Serapion says, there are two species of *essera*; but his distinctions do not seem well grounded.

The *essera* should be distinguished from that species of itch which appears in the form of dry pimples at the first; but these soon after have a thin serum lodged on their apex, like a small vesicle. Some authors confound the *essera* with the *epinyctides*; but the latter have also a thin humour which oozes from them. No danger attends this complaint.

The only indication is to allay the itching; but this object is with difficulty attained. Rubbing them with parsley juice has been said to take off this chief inconvenience; but the saliva is still more effectually employed in the same way. When it has been of some continuance, diuretics have been of service; interposing purgatives of the saline kind, to succeed a dose of calomel given at bedtime. See Sennertus, Sydenham, and Dr. W. Heberden's Remarks on the Nettle Rash, in the second volume of the London Medical Transactions.

ESTHIO'MENOS, (from *εσθια*, to eat). **EATING, CORRODING.** An inflammation in the skin, attended with a sharp humour, more properly the herpes exedens; or indeed any inveterate ulcer.

E'SULA, vel **E'ZULA**. **SPURGE.** There are many species of plants which bear this name, some of which rank under the article **TITHYMALUS**.

ES'ULA I'NDICA, *tithymalus orientalis arborescens, triquetrus, spinosus, and talukghaha*. The plant that produces the bogia gum differs not from this species of *esula*: but, as Sydenham observes, there are two species of gamboge; one collected from a plant called *cambo-dia*, and the best sort from the *codampulli*. *Euphorbia antiquorum* Lin. Sp. Pl. 646, though the latter plant is found not to furnish it.

The spurges generally agree in their containing a milky juice, which is violently emetic and cathartic; and, if applied to the skin, corrosive.

E'SULA MA'JOR, *tithymalus palustris fruticosus, tithymalus magnus multicaulis*, **GREAT MARSH SPURGE**, and **GERMAN SPURGE**; also the **GARDEN SPURGE**. *Euphorbia palustris* Lin. Sp. Pl. 662.

E'SULA MARI'NA. See **TITHYMALUS MARITIMUS**.

E'SULA MI'NOR, also called *pityusa, tithymalus foliis pini tithymala cypharissæ similis*, and **PINE SPURGE**, or the **COUNTRYMAN'S RHUBARB**. *Euphorbia cypharissæ* Lin. Sp. Pl. 661.

E'SULA SOLISE'QUA. The **SUN SPURGE**. See **TITHYMALUS HELIOSCOPUS**.

ETE'SIÆ, (from *ετος*, annus). North-eastern annual winds. Pliny observes, that the etesian winds set in two days after the dog star rises, and continue forty days. Prosper Alpinus informs us, that the etesian winds blow in Egypt when the sun enters Cancer, and continue almost the whole of June, July, and August; and that at the rising of these winds the Nile rises, and the pestilence ceases. The south wind brings the pestilence; and this wind they call *Campsin*, from Camp-

sis, a general, who, with his whole army, was suffocated in the sand which was driven upon them by this wind. It is a kind of sirocco, or rather a blast of hydrogenous gas, and not the sand which destroyed the general and his army. It is the simoon of the desert.

E'THIEL. It imports both fire and blackness. In the old alchemy, the words *ethel, terra alba, sulphur album, fumus albus, almagra, auripigmentum*, and *magnesia*, all mean the same thing.

E'THER. See **ÆTHER**.

E'THICA. See **HECTICA**.

ETHMOI'DES, *os*, (from *εθμος*, a sieve, and *ειδος*, a form). *Cribriforme, cribrosum, and coliforme os; foraminulentum; spongiosum os*. This bone is placed between the two orbits of the eyes, where a notch is left for its insertion. The cribriform lamella is the internal plain, thin, horizontal plate, which hath a middle eminence called *crista galli*, to which the beginning of the falciform process is attached: round the *crista galli*, except at the hind part, this lamella is pierced obliquely by many small foramina, through which the filaments of the olfactory nerves pass. From the middle of the cribriform lamella, the nasal lamella rises extremely thin, but at its anterior extremity it becomes thicker. At a little distance from each side of this lamella, a cellular bony substance is observable: the figure of the cells is uncertain; they communicate with the frontal sinuses, and with the cavity of the nose, and are the external lateral portion of the ethmoid bone: their outward posterior surface is smooth, called *os planum*; and it makes a part of the orbit. The *ossa spongiosa*, or *turbinata superiora*, are situated at the inferior parts of the cellules; their figure is oblong, and they are sharp at their extremities.

The cribriform lamella is the body, as it were, of the ethmoid bone; and it is so thin, that it may easily be penetrated by a probe: when hurt, the accident is usually fatal.

E'TRON, (from *εδω*, to eat; as containing the receptacle of the food). See **HYPOGASTRIUM**.

ETYTHO'XYLUM BRASILIA'NUM. See **BRASILIUM LIGNUM**.

EUANASPHA'LTOS, (from *ευ*, ease, and *αναφαλλα*, to recover strength). One who soon recovers.

EUA'NTHEMON, (from *ευ*, well, and *ανθεμος*, a flower,) from the beauty of its flower. See **CHAMÆMELUM**.

EUA'PHION, (from *ευ*, ease, and *αφν*, the touch). A medicine for the hæmorrhoids; named from its gentleness. Galen.

EUCARI'STOS. An epithet for an antidote in N. Myrepsus.

EUCHRO'ON. A plaster mentioned by Scribonius Largus.

EUCO'ILIA, (from *ευ*, bene, and *κοιλια*, the bowels; because they gently open the belly). See **CERASUS**.

EUDIOMETER. An instrument employed to ascertain the proportion of oxygen in any given quantity of atmospheric air. We had designed to give a particular account of the various contrivances for this purpose; but they have been found so little applicable to the purposes of medicine, that the detail would not be interesting in a work of this kind. Air obtained from

crowded rooms, from apartments where patients affected with the worst fevers have breathed, from the highest mountains, or the lowest valleys, scarcely differs. The principle on which this instrument acts is introducing a substance to common air, which has a powerful attraction for its oxygen.

EUELPIDI'UM. A liquid collyrium. See DIASMYRNON.

EUELPI'STI. A plaster described by Scribonius Largus.

EUE'MBOLOS, (from *ευ*, *well*, *εν*, *in*, and *βαλλω*, *to cast*). A practitioner expert at setting of bones.

EUE'METI, (from *ευ*, and *εμεω*, *to vomit*). Those who vomit with ease.

EUE'RES, (from *ευ*, and *ερελμος*, *an oar*). Easy to be rowed. But Hippocrates uses naval terms, and applies them to instruments: in his works it sometimes signifies *ready or handy*.

EUE'XIA, (from *ευ*, and *εξις*, *a habit*). A good habit of body.

EUGE'OS, (from *ευ*, and *γη*, *the earth*). See UTERUS, and HYMEN.

EU'LE, (from *ευλαζω*, *to putrefy*). A worm; properly one bred in ulcers.

EU'LOGIUM. In Forestus, from Rhases, it signifies the small pox, or measles.

EUNU'CHION. IMPOTENT. (See LACTUCA.) Venus, it is said, lay upon a bed of lettuces after the death of Adonis, to restrain her venereal inclinations.

EU'NYMO AFFI'NIS OCCIDENTA'LIS. See GUAIACUM.

EU'NYMUS, (from *ευ*, and *νομα*, *nomen*; *i. e.* having a good name,) *tetragonia*, *fusanus*, *fusaria*, PRICKWOOD, and the SPINDLE OF DISTAFF TREE; *euonymus Euroficius* Lin. Sp. Pl. 286. In France and Germany the wood is made into spindles. The fruit is emetic and cathartic; and if powdered, and sprinkled in the hair, it is said to kill lice. Raii Historia. See SIMAROUBA.

EUPATO'RIMUM, (from *ηπαρ*, *the liver*, because it is useful in disorders of that organ,) *hepatorium cannabinum*, WATER HEMP, WATER, DUTCH, and COMMON HEMP AGRIMONY. (See AGRIMONIA.) *Eupatorium cannabinum* Lin. Sp. Pl. 1173. It is a plant much used in Holland; found on the sides of ditches and rivers; acrid and bitter to the taste; but the leaves strengthening and aperient. Boerhaave informs us, that the turf diggers use them against foul ulcers, the scurvy, and swelling of the feet, to which they are very subject. The root is a cathartic and emetic; employed in cachexies and dropsies. Two ounces of the fresh juice, or a drachm of the extract, is a proper dose. Raii Hist. Also the name for a species of baccharis.

EUPATO'RIMUM A'RABUM. See BIDENS.

EUPATO'RIMUM GRÆCO'RUM; EUPATO'RIMUM VE'RUM et VE'TERUM. See AGRIMONIA.

EUPATO'RIMUM ME'SUE. See AGERATUM.

EUPE'PSIA, (from *ευ*, and *πεπτω*, *to digest*). GOOD DIGESTION.

EUPE'TALON, (from *ευ*, and *πελαλον*, *a leaf*, so named from the beauty of its leaves). See LAUREOLA MAS.

EUPHO'R'BIA PALU'STRIS. See TITHYMALUS.

EUPHO'R'BIA. So named by Juba, in honour of

Euphorbus his physician; *schadida-calli*, *tithymalus*, *aizoides fruticosus*, &c. The EUPHORBIIUM PLANT. BURN, THORNY PLANT, SPURGE. *Euphorbia officinarum* Lin. Sp. Pl. 647. It is a prickly lactescent shrub; from which the gummy, resinous, concrete juice, called *gum euphorbium*, exudes. It is brought from Barbary in drops, or tears, of an irregular form, some of which, when broken, contain little twigs, and other vegetable substances. The tears are brittle; of a gold colour outwardly, and white within: they consist of equal parts of resin and gum; but their acrimony resides in the resin.

The spirituous tinctures are very pungent, and when inspissated more so. The watery infusion and extract are bitterish, with a slight, though durable, acrimony. Neither spirit nor water carries over any portion of this gum in distillation.

Euphorbium is too acrid for internal use; but is an ingredient in some stimulating plasters used in palsies and other disorders. The two compositions of this kind are formed in the following manner:

EMPLASTRUM EUPHORBII. R. Picis burgundicæ ℥ iv. euphorbii ℥ ss. terebinthinæ vulgaris q. s. picis burgundicæ liquefactæ adjiciantur euphorbium bene in pulverem redactum, et terebinthinæ portio, adeo ut in spissitudinem propriam abeant. This is a powerful stimulant, well calculated to relieve diseases of the hip joint in their early stage.

EMPLASTRUM EX EUPHORBIO. R. Emplastri lithargyri ℥ ij. ss. euphorbii bene pulverizati ℥ iij. picis burgundicæ ℥ ss. euphorbium cum olei paululo in mortario teratur, postea, alia, prius liquefacta, adjiciantur. This is highly recommended for promoting the suppuration of sluggish ulcers.

Some have used euphorbium as an errhine; but it is too active for this purpose, since in very small quantities it is liable to act with violence; the fine dust which rises in powdering affects the operator's head and throat very powerfully. Cullen's Mat. Medica.

In the 2d vol. of the Medical Museum is an instance of a person, who, through mistake, swallowed some tincture of euphorbium, and was relieved by frequent draughts of water and olive oil, with a small quantity of camphor. The symptoms produced by the euphorbium were a burning pain in the mouth, throat, and stomach, with a violent suffocation.

EUPHO'R'BIA PARVIFLORA, Lin. Sp. Pl. 653. An Indian herb recommended for syphilis.

EUPHO'R'IA, (from *ευ*, and *φωρω*, *to bear*). Bearing a disorder, or the operation of a medicine, easily.

EUPHRA'GIA, EUPHRA'SIA, (from *ευφρων*, *joyful*; because it exhilarates the spirits,) *ocularia*, EYE BRIGHT; *euphrasia officinalis* Lin. Sp. Pl. 841. It is a herb with small, oval, serrated leaves, set in pairs without pedicles: the flowers appear on the top of the stalks; are white outwardly, but inwardly streaked with purple and yellow. It is annual, grows wild in uncultivated grounds, and flowers from July to September.

It is a very mild astringent, and hath been much extolled in disorders of the eyes. Both spirit and water extract its virtues. An infusion, and sometimes the powder in the manner of snuff, are taken in cases of weak sight. The following preparation, called *pulu.*

helidæi, hath been held in great repute. R. Euphrasia ʒij. macis ʒss. m. f. pulv. cap. ʒi. ad ʒij. Euphrasia is an ingredient in the British herb tobacco.

EUPHRA'SIÆ AFFINIS. BRASILIENSIS-SILICOUSÆ. See CAA-ATAVA BRASILIENSIS.

EUPORISTA, and EUPORISTON, (from *ευ*, *easy*, and *πορεω*, *to afford*). Medicines easily prepared.

EURYTHMIA, (from *ευ*, and *ρυθμος*, *order*). It imports dexterity in handling instruments. *Eurythmus* means the proper order of the pulse. See ARYTHMUS.

EUROPEÆ. See VERONICA.

EUSARCHUS, (from *ευ*, and *σαρξ*, *caro*). PLUMP.

EUTHE'SIA, (from *ευ*, and *τιθημι*, *put together*). An innate strong habit of body. Galen.

EUTHYPO'ROS, (from *ευθως*, *straight*, and *ποριζω*, *to pass into*). Extension in a straight line, made with a view to reduce a broken limb.

EUZOMON, (from *ευ*, and *ζωμος*, *broth*; from giving a flavour to broth). See ERUCA.

EVACUANTIA, (from *evacuo*, *to evacuate*). Medicines suited to promote the discharge of fluids either by the secretories, or in more artificial ways, as bleeding or blistering. The former produce their effects by a stimulus, adapted only to the organ by which the discharge is excited; a subject of future consideration. The latter discharge the fluids, or at least their proper portion, indiscriminately. The evacants are errhines, sialagogues, expectorants, emetics, cathartics, diuretics, diaphoretics, and emmenagogues, q. v.

These produce their effects on general principles, which occasion other changes, according to the skill of the administrator, and not by a particular power of selecting diseased humours from the healthy. The good and the bad are mixed in the body, and are evacuated in the same proportions.

EVACUATIO. See EXCRETA, and RETENTA.

EVACUATORII. Diseases attended with increased discharges.

EVAPORATIO, (from *evaporo*, *to evaporate*). EVAPORATION, *anathymiasis*. The conversion of fluids, and sometimes even solids, into gaseous invisible fluid, probably into air. This process has been attributed to a solution of the fluid in air; but evaporation takes place in vacuo: even mercury exhales in the Toricellian vacuum, and ice in the open air. Water by evaporation seems to be decomposed; but the other phenomena have not yet been explained.

In pharmacy, some solid bodies are recovered from their state of solution by evaporation, by means of heat. This process is applicable to all those substances which are less volatile than the menstruum; as, solutions of alkaline salts, and the inodorous parts of vegetables and animals from water; resinous and odorous bodies from spirits of wine. The tincture of mint, for instance, made with spirit of wine, leaves a resin rich with the properties of the herb on the evaporation of the spirit.

EVERRICULUM, (from *everro*, *to sweep away*). An instrument resembling a spoon used to clear the bladder from gravel after lithotomy. Parè.

EVE'RSIO, (from *everto*, *to turn aside*). See ECTROPIUM.

EXACERBANTES. REMITTING FEVERS.

EXACERBATIO, (from *exacerbesco*, *to become violent*). EXORESSENTIA. See PAROXYSMUS.

EXACINATA, (from *exacino*, *to take out the ker-*

nels). Fruits which have their stones taken out. See ACINUS.

EXÆ'MA, (from *εξ*, *ex*, and *αιμα*, *sanguis*; *exanguis*). A privation of blood in a considerable degree. Hence *exæmos* differs from those called *leiphaimoi*.

EXÆ'RESIS, (from *εξ*, *out of*, or *away*, and *αιρω*, *to remove*). It is that part of surgery which consists of removing superfluities.

EXALMA, (from *εξαλλω*, *to leap out*). The starting of the vertebræ from their places. Hippocrates.

EXALTA'TIO, (from *exalto*, *to lift up*). EXALTATION. In chemistry it signifies an operation by which a substance is raised to a greater degree of virtue. Of exaltation there are two kinds: first, *maturation*; which is effected by digestion, fermentation, and projection: secondly, *gradation*. See GRADATIO.

EXAMBLO'MA, or EXAMBLO'SIS, (from *εξαμ-βλισκω*, *to miscarry*). See ABORTUS.

EXANASTOMO'SIS, (from *εξαναστομωω*, *to relax or open*). See ANASTOMOSIS.

EXANG. The abbreviation of *exanguis*. (See EXÆMA.) The bones and cartilages which are nourished with a white fluid are also called *exanguæ*.

EXANIA, (from *ex*, *out of*, and *anus*). The bearing down of the anus. See PROCIDENTIA.

EXANIMATIO, (from *ex*, *without*, and *anima*, *the mind*). LIPOTHYMIA, or DEATH.

EXANTHE'MA, (from *εξανθεω*, *to spring forth like a flower*). RASH. *Effloratio*, *efflorescentia*, and *epanthema*. Red patches on the skin, variously figured, in general confluent, or diffused irregularly over the body, leaving interstices of a natural colour. Portions of the cuticle are often elevated in a rash; but the elevations are not acuminated. The eruption is usually accompanied with a general disorder of the constitution, and terminates in a few days. Fevers attended with these appearances are called *exanthematous*.

Exanthemata form the third order of Dr. Cullen's first class, *pyrexia*; and the propriety of establishing such an association will be obvious on the slightest consideration. It is so truly natural, that the doubt will only be whether it is not more properly a genus. The limits, however, of such an order are not easily fixed. If we look at some of the genera, the small pox and measles for instance, the limits will appear to be cutaneous eruptions from a specific virus, which produce the disease once only in the individual's life. This future immunity, however, is not constant to all the genera; and it is found in diseases not included in the order. Thus erysipelas, probably urticaria, more certainly pestis, recur in the same individual, while pertussis only attacks once in the life. We might refer to what we have said on cutaneous diseases, and endeavour to establish, on the same foundation, all the affections of the ephelion, but that the epidemic catarrh would stand in the way of the conclusion.

In the definition therefore of the exanthemata, the circumstance of the diseases affecting the person only once in their lives must be abandoned, or the erysipelas, and probably some others, must be expunged. In other respects the order is perfectly natural, if we exclude the plague, which, as we shall hereafter point out, connects the exanthemata with the fevers; and such connections as, in the natural method of botany, will be probably found important. In other respects the theory

of the exanthemata has been already explained under the CUTANEI MORBI, and require no further elucidation than they will receive under the article FEBRIS, q. v.

EXANTHEMATA SEROSA. SEROUS ERUPTIONS. See PEMPHIGUS.

EXANTHROPIA, (from *εξ*, and *άνθρωπος*, *having lost the faculties of man*). According to Wedelius, the third degree of melancholy.

EXARMA, (from *εξαιρωμαι*, *to be elevated*). An elevated tumour.

EXAR'SIO, (from *exardeo*, *to burn violently*). A great degree of heat. Increase of temperature, such as happens in hectic fevers.

EXARTHREMA, (from *εξ*, *out of*, and *αρθρον*, *a joint*). See LUXATIO.

EXARTHROS, (from the same). An epithet for a person whose joints are large and prominent, as if out of joint.

EXASPERATIO, (from *exaspero*, *to whet*). EXASPERATION. The increase of a disorder; also a rendering the skin rough.

EXCATHISMA, (from *εξ*, and *καθιζω*, *to sit in*). See SEMICUPIUM.

EXCEDENS, (from *excedo*, *to surpass*). In botany it means exceeding in length, comparatively long.

EXCITABILTY, and EXCITEMENT. The former of these is the capacity of the body to admit of increased action; and the latter the state of increased action. In Brown's system, excitability is the distinction of life, and the excitement of heat and other stimuli alone necessary (if we understand him) to produce life. When these are present, the body lives; when absent, it dies; and life is thus a flame kept up by constantly blowing.

EXCITING CAUSES. Those causes which excite the action of the predisponent ones. In the language of some pathologists they are external causes. See CAUSA.

EXCIPIENS, (from *excipio*, *to receive*). In prescriptions, that is called the excipient which receives the other ingredients, and gives them a proper form; as official electuaries, conserves, fobs, &c.

EXCI'PULUM, (from the same). In chemistry it is a receiver. See AMPULLA.

EXCISIO, (from *excindo*, *to cut off*). See AMPUTATIO.

EXCLUSORIUM, (from *excludo*, *to eject*). A medicine supposed to cause abortion. Fortunately, there are few such; and those little known.

EXCORIATIS, EXCORIATIO, (from *excorio*, *to take off the skin*). EXCORIATION, or ABRASION OF THE SKIN; *ecdora*.

EXCREMENTUM, (from *excerno*, *to separate*). EXCREMENT; or whatever requires to be discharged out of the body.

EXCRESCENTIA, (from *ex*, and *cresco*). AN EXCRESCENCE; *ecphyas*, *ecphysis*. A preternatural protuberance on any part of the body.

EXCRETA et RETENTA, (from *excerno*, *to separate*, and *retineo*, *to retain*). Fluids thrown out of the body, and those that are retained. These formed considerable objects of attention in the hygiene, during the reign of the humoral pathology; and while the importance of duly attending to the excretions, and their proportion to the ingesta and retenta, is still felt, and their regulation considered as equally necessary, the ab-

solute quantity is less regarded. It is now admitted that the system forms its own fluids, and regulates the quantities retained in general, as well as those thrown out. In diseases only it is necessary for art to interfere, and then to remove local accumulations rather than to lessen the absolute quantities.

EXCUTIA VENTRICULI, (from *excutio*, *to rub off*, and *ventriculus*, *the stomach*). A brush made of soft bristles, fixed in a flexible brass wire, with silk or flaxen thread wrapped round it. When used, the patient drinks a quantity of warm water; and the excutia, being dipped in some proper liquor, is passed down into the stomach, where it is moved around. The absurdity of this plan cannot be better exposed than by explaining it.

EXECHEBRO'NCHOS, (from *εξεκα*, *to abound*, and *βρονχος*, *a throat*). A prominent throat. See BRONCHOCELE.

EXECHEGLUTOS, (from *εξεκα*, and *γλουτος*, *the buttocks*). Prominent buttocks.

EXELCO'SIS, (from *ελκος*, *an ulcer*). See EXULCERATIO.

EXERMA, (from *εξεραω*, *to vomit up*). The matter ejected by vomiting.

EXERCITATIO, (from *exercito*, *to exercise*). EXERCISE. (See *ÆORA*.) The exercise of the body for the benefit of health is called gymnastic. (See GYMNASICA). The military exercises, gardening, husbandry, or other employments in the open air, conduce greatly to health; and moderate exercise in the open air, an hour or two before breakfast, improves the appetite and cheers the spirits: glandular obstructions are best prevented and cured by moderate exercise.

On the other hand, when exercise is too freely used, it occasions loss of appetite, loathing of food, costiveness, rigors, and fainting. In this case a moderate use of wine, warm bathing, quiet sleep, and a moist nourishing diet, afford the best relief. See Fordyce's Elements, part i. Mackenzie on Health.

EXERRHESIS, EXERRHO'SIS, EXERRHY'SIS, (from *εξερρωω*, *to flow from*). See ECROE.

EXFOLIATIO, (from *exfolio*, *to cast the leaf*). DESQUAMATIO. EXFOLIATION. The process by which the dead part of the bone separates from the sound. One principal cause of an exfoliation of a bone is an interruption of the continuity of the vessels which nourish it. The coldness of the air, by contracting and drying up the extremities of the small vessels of the bone, also checks the circulation of the nutritious matter through them. Mr. John Hunter observes, "that one part of a bone is never separated from another by the rotting of the dead part, for that which comes away is as sound as it ever was. Exfoliation takes place soonest in bones wherein are the fewest cells, and whose texture is the closest. Before any part of a bone can be thrown off by exfoliation it must be dead. But even then, till the process of exfoliation begins, the bone adheres as strongly as ever, and would remain for years before it could be separated by putrefaction alone. Bones are composed of two substances, viz. a true animal matter, and an earthy one, which are only intermixed with each other. A dead bone acts on the system in the same manner as any other extraneous body. It stimulates the adjacent living parts; in consequence of which, such a process is begun that must terminate

in its being thrown off. The effects of this stimulus are, first, that the living adjacent bone becomes more vascular; a circumstance which always takes place when a part hath more to do than is just sufficient for the support of life. Secondly, that the earth of the living part, when it is in contact with the dead bone, is absorbed; hence the bone becomes softer, and adheres by its animal matter only. Thirdly, that the living animal part is at last absorbed along the surfaces of contact: this part of the process commences long before the last is finished. Both of them begin first at the surface, though in their course they do not every where take place in an equal degree at the same time. Fourthly, in proportion to the waste made by the last part of the process, a fungus arises from the living surface, and fills up the intermediate space, so that there may be no vacuum. These different stages, taken together, constitute ulceration. When any part of a bone is once loose, it will be pushed to the surface in the same manner as most other inanimate bodies would be; and this stage is partly mechanical, partly a continuation of ulceration. A proof of the third stage above mentioned may be derived from those cases where people die while exfoliation is going on. A small groove or worm-eaten canal can then be discovered, which becomes gradually deeper, and follows the irregularities of the living and dead surfaces. After the application of the trepan, a circular piece of bone is frequently thrown off, which is always less than the space from whence it came. This, however, would never be the case, were there not a loss of substance."

When a bone is laid bare by any accident, and an exfoliation is feared, if several perforations are made in the bone, the exfoliation will be prevented: in such cases the wound should be kept clean, and defended from unctuous and watery applications: pledgets of lint are very proper; or they may be dipped in the mixture of the oleum terebinthinæ and tincture myrrhæ. Neither caustics nor the actual cautery, in Mr. Hunter's opinion, hasten exfoliation: they produce death only in part of the bone, which is the first step towards exfoliation. "If caustics ever hasten exfoliation where the bone is already dead, it must be by producing inflammation in the adjacent living bone; this brings about a change in it, and makes it exert a power which it was incapable of before." See CARIES.

EXFOLIATIVUM, (from *exfolio*, to shed a leaf). See DESQUAMATORIUM.

EXIPO'TICOS, (from *εξιπω*, to press out or filter). An epithet for digesting or deterring medicines: in Galen synonymous with attrahents.

EXITU'RA, (from *exeo*, to come from). A RUNNING ABSCESS: applied by Paracelsus to putrid excrements.

E'XITUS A'NI. See PROCIDENTIA ANI.

EXO'CHAS, or EXO'CHE, (from *εξω*, without, and *εχω*, to have). A tubercle on the outside of the anus.

EXOCY'STE, and EXOCY'STIS, (from *εξω*, without, and *κυστις*, the bladder). A prolapsus of the inner membrane of the bladder.

EXO'MPHALOS, (from *εξ*, out, and *ομφαλος*, a navel). Any protuberance of the navel. See HERNIA UMBILICALIS, and HYDROPS UMBILICALIS.

EXONCHO'MA, (from *εξ*, out, and *ογγος*, a tumour). Any large prominent tumour.

EXONEIRO'SIS, (from *εξ*, out, and *ονειρος*, sleep). NOCTURNAL POLLUTION, when in sleep the semen is ejected. This, if rare, may be from redundant vigour; if frequent, from weakness of the seminal vessels, or the indulgence of lascivious thoughts. It is seldom relieved by astringents. Cold-bathing is its chief remedy; but it is generally necessary to lessen the too great action of the spermatic vessels by sedatives. Camphor and nitre sometimes with opium are the most effectual. The latter causes are the most frequent.

EXOPHTHA'LMIA, (from *εξ*, out, and *οφθαλμος*, the eye,) *buphthalmus*, *echiemos*, *melon*; a dislocation of the eye. In this disease the globe, more or less distended, rises from its orbit, either from its own increase of size, or the enlargement of some part below; nor can it be covered by the palpebræ. The cure must depend on the nature of the cause.

EXORESCE'NTIA. See EXACERBATIO.

E'XOS, (from *ex*, without, and *os*, a bone). A LEECH. See HIRUDO.

EXOSTO'SES. See GUMMA.

EXOSTO'SIS, (from *εξ*, out of, and *οστων*, a bone). *Hyperostosis*, a tumour on a bone. Mr. Pott calls it an enlargement of the bone. Its hardness equals, or rather exceeds, that of the bone from which it proceeds. Mons. Petit calls the *spina ventosa* by the name of *exostosis*, but the disorders are very different. Dr. Cullen places this disease in the class *locales*, and order *tumores*, which he defines a hard tumour forming in the bone.

The exostosis is caused by a discharge of a superfluous quantity of ossific matter upon the part where it is seated, or from a separation of the bony lamellæ. The cause of each is an irritation arising from some degree of inflammation, often the effect of syphilitic virus. If from disease, the chief cause must be removed. Whatsoever, however, is called a venereal exostosis, is only an enlargement, or rather a thickening, of the periosteum. It is sometimes very painful, and should be distinguished from the rickets, which affect the ends of the bones chiefly; while an exostosis is rather in the middle of the long bones. The rickets are also sufficiently distinguished by the generally diseased habit. If no general disease exists, the patient may live to advanced age without any considerable inconvenience.

When the nature of the cause is understood, and we have reason to hope for success, the bone should be laid bare, and the diseased part taken away with a chisel. This will succeed if the habit is not much diseased; but if the constitution is also faulty, and the exostosis proceeds from the exuberance of bony matter, amputation is the only method of relief; though generally the case is most safely left to nature.

Sometimes a preternatural hardness of the ligament is called an exostosis; this spurious sort, as well as the venereal nodes, is relieved by mercurials.

Exostosis happening in the middle of hard bones are generally hard in all their parts; but those near the ends, or about the joints, have often only a hard external lamina. When this disorder happens on the bones within the skull, the consequence may be an apoplexy, epilepsy, or a palsy. See Petit's Diseases of the Bones, part ii. chap. xvi. Bell's Surgery, vol. v. p. 541.

EXO'TICUS. EXOTIC, (from *εξω*, without). Any thing brought from foreign countries.

EXPECTORANTIA, (from *expectoro*, to discharge from the breast). **EXPECTORANTS**, *bechita*, and *bechica*. Medicines suited to promote the excretion or rejection of mucus from the bronchial glands. Some expectorants operate by attenuating the mucus; others stimulate the excretories to promote the discharge. We employ expectorants when the mucus is too thin and acrid, when too viscid, or when the excretories are not sufficiently irritable to propel their contents. The former scarcely, perhaps, deserve the title; for they are principally mucilaginous substances; and where the mucus is thin and acrid, inflammation generally exists, not confined to the bronchial glands, but extending to the epiglottis and throat. Mucilages then sheath the inflamed organs, and relief, like the disease, is communicated to the parts below. For this purpose the gums, the mucilaginous seeds, liquorice, honey, extract of malt, starch, sugar, isinglass, glue, &c. are employed. Sometimes they are slightly acid, as the dried fruits of warmer climates, the hips, jelly of currants, sorrel, vinegar softened with the more sweet fruits, as raspberries and sloes. The latter are chiefly employed where there is also a relaxation of the throat and parts adjacent. Oils differently prepared are equally useful, and the coltsfoot, the butterbur, and the groundivy, supposed to possess a slight stimulus, are perhaps chiefly useful as mucilaginous. Independent of inflammation, the mucus is sometimes too thin and acrid, from too great irritability of the vessels of the bronchial glands, and we then employ opiates; the siliquosæ, as mustard, horse radish, and different species of *erysimum*; the *alliaceæ*; *elecampane*, and *orris-root*, the *seneka*, and *colchicum*. When the expectoration is too viscid, or the vessels not sufficiently irritable to assist the excretion, expectorants, strictly so called, are useful. These are the more stimulating medicines just mentioned; to which may be added all the variety of fetid gums, the turpentine, including the balsams, the tobacco, and the squill. Steams of warm water, impregnated with vinegar, aromatic herbs, ether, oil of wine, and carbonic acid, are adapted to the same purpose; and nauseating medicines, as well as emetics, are powerful expectorants; the antimonials and *ipecacuanha*, perhaps, when inflammation exists; but the squill, the *colchicum*, and the *seneka*, in the other cases. The *digitalis* seems only to act as an expectorant when it nauseates.

Dr. Cullen has found it difficult to explain the action of expectorants; but we have as much reason to suppose that the stimulus of some medicines may be conveyed to the lungs, as of others to the kidneys, or the extreme vessels. We evidently find them conveyed to these organs by the smell imparted to the breath, and the difficulty of explaining the action of specific stimuli will always recur. On this subject the difficulty is perhaps less than on some others, since the vessels of the lungs alternate so regularly in their discharges with those of the skin, and, unlike all other glands, are occasionally excited by increased temperature alone. Their action alternates also with the mucous glands of the intestines; for we find in the pneumonia a supervening diarrhoea constantly checks the expectoration.

EXPECTORATIO. **EXPECTORATION**, (from *ex*, and *pectus*; or from *expectoro*, to throw out of the breast). See **EXPECTORANTIA** and **ANACATHARTICA**.

EXPELLENTIA, (from *expello*, to drive out). Me-

dicines supposed to drive out morbid humours from the body.

EXPIRATIO, (from *expiro*, to breathe forth). *Expneumatosi*s, *expneæ*. The expulsion of air from the lungs. See **RESPIRATIO**.

EXPLORATIO, (from *exploro*, to search out). **EXPLORATION**. Probing a wound or ulcer.

EXPLORATRIX. See **CUPELLA**.

EXPLOSION, (from *explodo*, to drive off). **EXPLOSION**; in chemistry, detonation, or fulmination.

EXPRESSIO, (from *exprimo*, to press out). **EXPRESSION** is a mechanical operation by which the juices of many plants are obtained, and sweet oil extracted, from olives, almonds, or lintseed.

This operation is effected by first bruising the substance, and then forcibly squeezing it in the press. The more succulent bodies may be bruised and wrapped in a linen cloth before they are committed to the press; but more viscid subjects require that a little water be previously added.

When an oil is to be obtained from seeds, the cheeks of the press should be gently heated, that the product may be increased: but when oils are to be taken internally, cold expression is the most proper, as heat disposes the oil to become soon rancid. Some of the aromatics yield a pungent oil; but that from mustard seed is insipid, and from poppy seed wholly free from any narcotic power.

EXSERTUS, (from *exsero*, to thrust out). In botany it is applied to the stamen, and means appearing above the corolla.

EXSICCATIO, (from *exsicco*, to dry up). **DRYING**. This pharmaceutic operation is effected by exhaling the moisture from the body, to be dried over a gentle fire, or by absorbing it, as when such subjects are laid on chalk stones for this end. Plants or their leaves should be dried in a free air without sun, and frequently turned. Tender flowers, which may lose their colour or aroma by long exposure to the air, may be dried by a gentle heat.

When great heat is employed, the operation is styled *coction*, *insolation*, or *torrefaction*; the first relates to fluids, the second to fluids and solids, and the third to solids only. Decantation and filtration are subservient to the process of *exsiccation*.

EXSTIPULATUS, (from *ex* priv. and *stipula*, straw or stubble). In botany it means without the haulm, or stubble.

EXSTASIS. See **ECSTASIS**.

EXSUCCATIO, (from *ex*, out of, and *succus*, juice). See **ECCHYMOMA**.

EXTENSOR, (from *extendo*, to stretch out). An **EXTENDER**. This name is given to several muscles.

EXTENSOR CARPI RADIALIS. This muscle takes its origin from the rising line of the *os humeri*, that runs towards the outer condyle, and from the same condyle it runs close to the radius; and passing through a groove where it is bound down, it divides into two tendons: the muscle in this part is sometimes called *bicornis*. One of these tendons is inserted into the basis of the first, and the other into that of the second, metacarpal bone. This muscle is occasionally called the *radius externus*; sometimes *extensor carpi exterior*, and *geminus*; by Winslow *ulnaris externus*.

EXTENSOR CARPI ULNARIS, is sometimes called

extensor carpi interior. It rises from the outer condyle of the os humeri, and then originates from the edge of the ulna; its tendon passes in a groove behind the styloid process of the ulna; it proceeds and is inserted into the inside of the basis of the metacarpal bone of the little finger.

The extensors, whether belonging to the fingers or carpus, arise from the outward extuberance of the os humeri: and their antagonists, the flexors, from the internal protuberance of the same bone, as well as from the upper and external part of the ulna next to the anconæus.

EXTE'NSOR DIGITO'RUM COMMU'NIS is also called *digitorum tensor*. It partly rises from the outer condyle of the os humeri, and partly from the outer edge of the ulna; passes behind the lower extremity of the radius, where there is a groove for its lodgement, and forms four tendons: that for the little finger differs in its passage from the others; the three last communicate, and are inserted into the second bone, and partly into the last of the respective fingers, that is, the third, middle, and fore fingers.

EXTE'NSOR DIGITO'RUM BRE'VIS is also called *pediculus*. It rises from the anterior part of the os calcis, runs across the instep, and divides commonly into four tendons, sometimes only into three, which are inserted into the three toes next to the greater one, or into all the four.

EXTE'NSOR DIGITO'RUM LO'NGUS; *enemodactylæus*; by Dr. Hunter *extensor longus digitorum pedis*. It rises from the upper part of the tibia and fibula, and the interosseous ligament; its tendon passes under the annular ligament, and then divides into five, four of which are inserted into the second and third phalanges of the toes, and the fifth goes to the basis of the metatarsal bone. The last Winslow reckons a distinct muscle, calling it *peronæus brevis*.

EXTE'NSOR I'NDICIS is also called *indicator*, and *extensor indicis proprius*. It rises with the extensor digitorum communis, lies between the ulna and radius, runs close to the interosseous ligament, passes over the back of the hand, and is inserted into the posterior part of the index.

EXTE'NSOR LO'NGUS rises from the inferior costa of the scapula; and the

EXTE'NSOR BRE'VIS rises from the outer spine of the humerus; they then make one tendon with the brachiiæus internus.

EXTE'RNUS MI'NIMI DIGITI, is also called *auricularis*. It rises partly tendinous at the extremity of the external apophysis of the os humeri, and partly fleshy from the superior part of the ulna, and becomes tendinous as it passes under the annular ligament at the carpus, where it is divided into two, and sometimes into three, tendons, which are united into one at its insertion into the superior part of the third bone of the little finger.

EXTE'NSOR PRI'MI INTERNO'DII PO'LLICIS rises high up from the radius, ulna, and interosseous ligament: it turns round the radius, runs across the carpus, and is inserted into the trapezium, and the first bone of the thumb.

EXTE'NSOR SECU'NDI INTERNO'DII PO'LLICIS rises from the radius, and the interosseous ligament describes

the same course as the preceding, and is inserted into the second bone of the thumb.

EXTE'NSOR TE'RTII INTERNO'DII PO'LLICIS rises from the back part of the ulna, near the middle, and from the interosseous ligament; then goes obliquely across the carpus to the third bone of the thumb. Its action not only extends, but also brings the thumb backward, so that the end of the thumb can sometimes be brought to the wrist.

EXTE'NSOR POLLI'CIS LO'NGUS rises from the middle and fore part of the fibula, and the interosseous ligament, and passes over the instep to be inserted into the last bone of the great toe.

EXTE'NSOR PO'LLICIS BRE'VIS is only a slip from the extensors of the toes, inserted into the first bone,

EXTE'NUATIO, (from *extenuo*, to diminish). LEANNESS. This may arise in two ways: one from the increased evacuation of the nutritious particles; the other from cacochymia, or a deprivation of the fluids. Prosper Alpinus observes, in his Presages of Life and Death, that if, after being extenuated by a disease, the body continues lean, though the nutriment be duly received, it denotes a relapse. Again, leanness from a spitting of blood, attended with a slow fever, is highly dangerous; and it is equally a bad sign in an ardent fever for the body not to become speedily lean, or to waste rapidly: the first prognosticates a tedious disease; the latter, death.

In general, leanness is not a disease; and, whatever are the evacuations, or the degree of extenuation, if without fever, and the appetite keeps up, there is little danger. Extenuation alone is not a disease, nor a predisponent cause: the same cannot be said of its opposite, obesity. An acrimony in the fluids rather than increased discharges occasions it; but the source of the greatest emaciation is the effusions of dropsy. The body is never so thoroughly extenuated as in dropsy, though greatly so in hectic, from absorbed purulent matter, and cancer. Some recent remarks, by Dr. Pemberton, in his Practical Treatise on various Diseases of the Abdominal Viscera, are so truly ingenious and comprehensive, that we shall select them in his own words. We cannot compress or give them in language more scientific and elegant.

"A proneness in the body to waste or not, as the same disease shall happen to be situated in this or that part, is in itself a circumstance very remarkable; and as an attention to this proneness may help to lead us through the obscurities which too often attend internal complaints, it is a subject well worthy of further consideration.

"To assist us in this inquiry it may be right to specify a few examples, where the difference of the effect of disease on the bulk is most striking. Let us take the two cases, of a diseased state of the mesenteric glands, and a diseased or scrofulous affection of the breast. In the former we shall find there is a great emaciation; in the latter, none at all.—In an ulceration of the small intestines, great emaciation takes place; in scirrhus of the rectum, none.—In a disease of the gall bladder, which is subservient to the liver, the bulk of the body is rapidly diminished; but in a disease of the urinary bladder, which is subservient to the kidneys, scarcely any diminution of bulk is to be perceived.—In

an abscess of the liver the body becomes much emaciated; but in an abscess of the kidneys the bulk is not diminished.

“If we examine into the functions of those parts, the diseases of which do or do not occasion emaciation, we may perhaps be led to the true cause of this difference of their effect on the bulk. In order, however, to understand more clearly how the functions of these parts bear relation to each other, it may be necessary to premise, that the glands of the body are divided into those which secrete a fluid from the blood for the use of the system, and those which secrete a fluid to be discharged from it. The former may be termed glands of supply; the latter glands of waste.

“The small intestines, in consideration of the great number of absorbents with which they are provided for the repair of the system, may be considered as performing the office of glands of supply.

“The large intestines, on the contrary, may be considered as performing the office of glands of waste; inasmuch as they are furnished very scantily with absorbents; and abundantly with a set of glands which secrete or withdraw from the system a fluid, which serves to lubricate the canal for the passages of the fæces, and which itself, together with these fæces, is destined to be discharged from the system.

“I have often imagined that this mode of considering the subject might, in many cases, assist us in approaching to the seat of a chronic disorder, by deciding where the disorder is *not* situated, and consequently by contracting within narrower limits the difficulties of our researches.

“Thus the symptom exhibited by the patient either in retaining his bulk, or in being emaciated, might serve as a diagnostic, according to my conception, for the purpose of deciding whether the disorder is seated in the glands of supply, or in the glands of waste.

“The glands which secrete a fluid to be employed in the system, as well as the glands of direct supply, may be considered the liver, the pancreas, the mesenteric glands, perhaps the stomach, and the small intestines: and the glands of waste are the kidneys, breasts, exhalant arteries, and the large intestines.

“In an abscess of the liver, and an abscess of the kidneys, both of which glands frequently run into suppuration, without exhibiting any pain in the part affected, it seems impossible to decide in what part of the system the derangement manifested in both these cases by the hectic fever is situated.

“According to the foregoing idea, if emaciation takes place, we might then determine that the disorder must be situated in a gland of supply; and thus we should be led to decide, that the disorder was certainly not in the kidneys, consequently we should be secured from the danger of misapplying our remedies upon a part which was not affected.

“The same hectic attends a chronic disease of the mesenteric glands, and of the small intestines: and here likewise, if emaciation does not take place, we should decide that the disorder was not situated in these parts, or in the liver.

“Now it is surely of considerable importance to determine where the disorder is not found, that our enquiries may be solely directed to those parts in which it is to be found.

“If this position respecting the bulk of the body, under disease, should be admitted as true, will it not afford a probability that the spleen, whose diseases produce great emaciation, is a gland of supply?

“What has been here advanced must be considered as applying to local diseases unattended by pain, as pain will itself sometimes waste the body, though sometimes it will not. Here, too, the wasting from pain seems to vary according to the part from which it proceeds. A stone in the bladder of urine, or in the kidneys, nearly stopping the discharge of urine, and occasioning the greatest pain, will not in the least affect the bulk; but a biliary stone, under similar circumstances, will occasion great and rapid emaciation.”

EXTENUA'TIO TYMPANI AU'RIS. See LAXATOR EXTERNUS.

EXTI'NCTIO, (from *extinguo*, to put out). See COMMUNITIO.

EXTIRPA'TIO, (from *extirpo*, to eradicate). AMPUTATION.

EXTRA'CTIO, (from *extraho*, to draw from). EXTRACTION. The liquors which dissolve bodies in their pure state, separate them from impurities, or rather extraneous bodies with which they are mixed. Extraction is performed by macerating the subject in its appropriated menstruum in the cold; by digesting or circulating it in a moderate warmth; by infusing it in a boiling fluid, and suffering them to stand until they are cold; or by actually boiling it for some time. Heat greatly expedites extraction; but it is injurious to some substances, by occasioning the menstruum to take up their more gross and disagreeable parts: yet others impart but little to a heat below that of boiling water. As heat promotes, so cold prevents, extraction, and occasions a deposition of what heat had enabled the menstruum to take up.

Vegetable juices obtained by expression, exposed to a heat, are gradually inspissated; and the mass is now styled, instead of an extract, an *inspissated juice*. The term extract is still retained, when a watery decoction or infusion is evaporated; but if a spirituous tincture be thus treated, it is called a *resin* or *essential extract*. Dr. A. Duncan proposes to call extracts *extractives*; but the latter is a component part of vegetables of a peculiar nature, and the former any thing separated.

Inspissated juices, when evaporated only to the consistence of honey or oil, are called *rob*, or *sapa*. Spirituous tinctures reduced to a like consistence are called *balsam*. See the New Edinburgh Dispensatory, by Andrew Duncan, jun. M. D.

Extraction, in surgery, is the drawing from or out of the body any thing fixed in it, as a thorn or a bullet in the flesh, a tooth from the jaw, or hairs from the skin.

EXTRA'CTUM, (from the same). An EXTRACT, *ecchyloma*. (See EXTRACTIO.) The name is taken from the substance which affords this extract, as EXTRACTUM CHAMÆMELI, CORTICIS PERUVIANI, &c.

EXTRA'CTUM PURGA'NS. See HEDERA ARBOREA.

EXTRAVASA'TIO, (from *extra*, and *vasa*, out of the vessels). EXTRAVASATION; applied to any part of the fluids of the body out of their proper vessels: thus an ecchymosis, sugillation, or aneurism, may be called *extravasation*. Extravasated blood, if the air has no access, will not putrefy.

An extravasation on the brain produces apalsy of one leg or arm, or both; dizziness; sleepiness; impaired sight; ravings; bleeding at the nose or ears; vomiting; loss of sense, or stupor. See CEREBRI COMPRESSIO, and CONCUSSIO.

Wounds on the head with extravasations are very fallacious, because the extravasation may be between the skull and the dura mater, and under it at the same time; under the pia mater, or in several other parts of the brain: but when these happen, the symptoms immediately portend danger.

Whenever the dura mater, either by depression, fissure or fracture, loses its adhesion, there will be, from its broken blood vessels, an extravasation immediately under the bone. An extravasation is less considerable when a fracture of the skull happens, than when there is a fissure. An extravasation is also more or less dangerous, according to the part of the brain injured. Extravasations from a blow are most commonly found between the skull and the dura mater; in this case a lethargy or other symptom will continue, until the extravasation be removed.

The practice recommended by Mr. Bromfield in fractures and concussions of the brain (see CONCUSSIO) may be useful in some degrees of extravasation; but he adds, that when violent accidents have happened to the head, an issue in the opening, formed by the separation of the additamentum of the temporal bone, is of singular advantage. See his Chirurgical Observations, vol. i.

EXTRAVE'RSIO, (from *extraverto*, to turn out).
EXTRAVERSION. In chemistry it is the discovery of any thing saline, alkaline, or acid, concealed in mixed bodies, the reverse of one species of concentration.

EXTRI'NSECI, (from *extra*, without, *in*, and *secus*, toward). The external parts, particularly the limbs, and the painful disorders which affect them.

EXTUBERA'NTIA, (from *extubero*, to swell out).
Tumours seated under the skin.

EXU'BERES, (from *ex*, without, and *uber*, a dug).
Children who are weaned.

EXULCERA'TIO, (from *exulcero*, to cause ulcers,) *ulcus*, and *exelcosis*; but generally applied to those early erosions which destroy the substance, and form an ulcer, or to an excoriation beginning to suppurate.

EXULCERA'TIO O'SSIS. See CARIES.

EXULCERA'TUS. See APERTUS.

EXUMBILICA'TIO, (from *ex*, out of, and *umbilicus*, the navel). A protuberance of the navel.

EXUNGULA'TIO, (from *exungulo*, to pare the hoofs or nails). EXUNGULATION; the cutting off the ungues, or white part of the petals of roses.

EXU'VIÆ, (from *exuo*, to strip off). See ANGUUM SENECTÆ.

EXYDA'TOO, *εξυδασιου*, in *aquam resolvo*, unde *εξυδασις*. When, instead of blood, a watery humour is generated and collected; whence water readily appears within the skin. Castelli.

EZQUAHDU'ITL. The DRAGON BLOOD TREE.

F.

F A B

F Æ C

F. or **F^c**. are abbreviations of fiat, or fiant, in prescriptions, viz. **f.** or **f^c**. haustus, *let a draught be made*.

FA'BA, quasi *faga*, (from φαγω, *to eat*, it being originally the food of man). The BEAN, *cyamus, phaseolus*. This plant hath a long unicusular pod, full of kidney shaped seeds; the stalks firm; the leaves in pairs, and, as it were, conjugated to a rib which ends in a point.

By the Falisci, a people of Hetruria, the bean was called *haba*; and from thence, perhaps, *faba*. Martinus derives it from φαω, *to feed*. Bean seems to be from the Italian word *baiana*.

FA'BA BENGAL'NSIS, **FA'BA CAMBA'IA**, **FA'BA MALA'BARICA**. See MYROBALANI.

FA'BA CRA'SSA. See CRASSULA.

FA'BA ÆGYPTI'ACA; *cyamos Ægyptiacus, nymphæa Indica, glandifera, Madaraspatana, bem tamara, nelumbo, lien Sinarum, colocasia, ciborum*, and *cibotium*, from the manner of planting it. The PONTIC or ÆGYPTIAN BEAN. *Nymphæa nelumbo* Lin. Sp. Pl. 730, though, by later botanists, it is referred to a new genus, *nelumbium*. It grows on marshy grounds in Ægypt, and some of the neighbouring countries. When the flower falls, a small pod appears, in which the bean is lodged. It is eaten either raw or boiled, and is a tonic and astringent. See Dale.

FA'BA FEBRI'FUGA. See NUX VOMICA.

FA'BA GRE'CA LATIFO'LIA. See GUAJACANA.

FA'BA I'NDICA, and **SA'NCTI IGNA'TII**. See NUX VOMICA SERAPIONIS.

FA'BA INVE'RSA, **CRA'SSA**, and **TELEPHII**. See CRASSULA.

FA'BA MA'JOR, and **CYAMUS LEGUMINO'SA**; *phaseolus major*, TURKEY BEANS, and GARDEN BEANS.

They are a strong flatulent food, nutritious, but indigestible, especially when old. The flowers afford an agreeable fragrance, which they impart to water by distillation. The fresh leaves beat into a poultice with cream are cooling and repellent. The ancients call the flour of beans *faba fresca*, and *lomentum fabæ*; because it is prepared without the skin, in which lies the astringency, generally attributed to the flour. Raii Historia.

FA'BA MINOR, also called *egina fresca*, HORSE BEANS. These differ no other way from the garden species than in being less.

FA'BA PECNU'RIM. Probably from a species of lau-

rel. The fruit is oily, and a warm aromatic. The bean possesses these qualities in a less degree; but has been employed in Sweten in stomach complaints, in colic, and diarrhœa. The infusion prepared in a close vessel is highly aromatic; but the aroma is lost by exposure to air, and by boiling. The smell of the bean resembles sassafras. The taste is aromatic, and it dissolves in the mouth.

FA'BA PURGA'TRIX. See CATAPUTIA MINOR.

FA'BA SUI'LLA. See HYOSCYAMUS NIGER.

FABAGI'NEA, and **FABA'GO**, (from *faba*, a bean.) *Capparis portulaca, pepilos Lutetianorum, telephium*, and *capparis fabago*; *zygophyllum fabago* Lin. Sp. Pl. 551. A bitter plant, which the Syrians use for killing worms.

FABA'RIA (from *faba*, a bean). See CRASSULA.

FABRO'RUM A'QUA, (from *faber*, a smith). Water in which hot iron is quenched.

FACIA'LISNERVUS. The portio dura of the auditory nerve. These nerves are styled the seventh, but by late authors the eighth, pair. They arise from the fourth ventricle of the brain, and passing through the petrous portion of the os temporis, are dispersed on the face.

FA'CIES, (from φαω, *to appear*). THE FACE. It comprehends the fore head, eye brows, eye lids, eyes, nose, mouth, chin, cheeks, and ears. Its bones are those of the upper and lower jaws.

FA'CIES HIPPOCRAT'ICA. THE HIPPOCRATIC or CA-DAVEROUS FACE. The nose is sharp, the eyes hollow, temples sunk, the ears cold and contracted, and their lobes inverted; the skin about the forehead hard, tense, and dry; the countenance pale, greenish, or dark. If it appears within three days after the attack of an acute disease, it is a fatal symptom. See DEATH.

FA'CIES RU'BRA. See GUTTA ROSACEA.

FACU'LTAS, (from *facio*, *to do*). A FACULTY; or the power of performing any action. The animal faculty is the power of exercising sense, motion, and the principal functions of the body. The mental faculties may be reduced to imagination, reasoning, and memory. See ACRIO.

FÆ'CES. See FÆX.

FÆ'CU'LA, (dim. of *fæx*). A component part of vegetables, nearly resembling mucilage, differing only from it by being soluble in cold water: in hot it becomes mucilaginous.

FÆCULA BRYO'NIÆ. The **FÆCULA** OF **BRYONY**. Take of the roots of white bryony any quantity; scrape them, and squeeze out their juice; which, after standing a little while, deposits a sediment, from which the thinner part may be separated by decantation, and the rest dried for use. Other *fæculæ* are extracted in the same way. Sago, potato flour, cassada, and indigo, are *fæculæ*, and by nitric converted into the malic or oxalic acid. In making starch, which is also a *fæcula*, the extractive and glutinous parts are destroyed by fermentation.

FÆX, quasi *fax*, (rom $\pi\rho\tilde{\nu}\tilde{\iota}\varsigma$, from $\pi\rho\tilde{\nu}$, to sink to the bottom,) *chersa*. It is properly the sediment, or lees, or grounds, of any fermented liquor; but in medicine it is generally understood of wine. The alvine excretions are thus called.

FAGA'RA MA'JOR, (from *fagus*, the beech, which it resembles). *Cayutana Luzonis, cubebis. Fagara pterota* Lin. Sp. Pl. 172.

It is a plant found in the Philippine islands. The berries are aromatic, and, according to Avicenna, heating, drying, good for cold weak stomachs, and astringent to the bowels: the outer rind was not used. Jacquin refers to this genus a plant with the trivial name of *octandra*, used as a perfume.

FAGA'RA OCTA'NDRA. See **TACAMAHACA**.

FAGOPY'RUM, et **FAGOTRITICUM**, (from $\phi\alpha\gamma\omicron\varsigma$, the beech, and $\omega\tilde{\iota}\tau\omicron\varsigma$, wheat, because its seed resembles the mast of beech). *Fru mentum Saracenicum, erysimum Theophrasti, tragopyron*, BRANK, BUCK WHEAT. *Polygonum fagopyrum* Lin. Sp. Pl. 522.

Though originally from Africa, it thrives every where; delights in a wet soil; is sown in fields; flowers in July; is less nutritive than barley and rye, but more so than millet or panic. Raii Hist.

FA'GUS, called *oxya; balanda; valanida*. The **BEECH TREE**. *Fagus sylvatica* Lin. Sp. Pl. 1416. Its leaves resemble those of the horn-beam: the fruit is produced at a remote distance from the flower, but on the same tree, and is a callous substance, acuminate, inclosing two triangular seeds or nuts. It grows in woods and in hedges. The mast (i. e. fruit) agrees in its properties with those of the chesnut. The oil expressed from beech nuts is supposed to destroy worms: a child may take two drachms of it night and morning; an adult an ounce. The poor people in Silesia use this oil instead of butter. Raii Hist.

FAIRBURN WATER. Fairburn is in the county of Ross, in Scotland, about two miles from the Castle-Leod well. It is a strong sulphureous water, of the same nature, but not so active: a gallon, on evaporation, yielded, of absorbent, dark coloured, light earth, two grains; of white calcareous earth, fifteen; of Glauber salt, mixed with yellow matter, &c. twenty-four grains; without any selenites. It is used for the same purposes as Castle-Leod waters, but not so much frequented. Monro's Medical and Pharmaceutical Chemistry, vol. ii.

FALCIFORMIS PROCE'SSUS, (from *falx*, a scythe, and *forma, likeness*). See **DURA MATER**.

FALDE'LLA. Contorted lint used for compresses.

FALX. A SCYTHE, (from the Hebrew term *phalah*, to cut). See **DURA MATER**.

FA'MES, (from $\phi\alpha\gamma\omega$, to eat; because it is the stimulus to eat). **HUNGER**; that peculiar sensation of the stomach which excites a desire for food, according

to Willis, arising from acid effluvia, and vapours, affecting the animal spirits in the left orifice of the stomach, and its nerves; and by consent of continuity, the internal coat of the stomach itself and throat; an impression communicated to the brain, by which the animal spirits are in like manner affected. Thus, when the stomach is empty, or when we fast longer than ordinary, it is common to say that the stomach pinches us. But as the liver is not at that time sustained by the stomach and intestines, it descends by its own weight; and, principally by means of its middle ligament, pulls the diaphragm along with it: it is in that place, therefore, that we have this uneasy sensation, and not at the superior orifice of the stomach, as is generally thought. See Haller's Physiology.

Some physiologists have attributed hunger to the stimulus of the gastric juice; yet all these opinions have little foundation. The theory of Willis is purely hypothetical, and the second rests on an erroneous idea of the anatomy of the parts. The third is the most plausible; but we have had reason to think, that this supposed powerful agent is only the remains of former meals. Dr. Cullen, with more reason, attributes hunger to the uneasy contraction of this viscus, when no longer distended. It is evidently a sensation peculiarly nervous, since the greatest desire of food at once vanishes, if any cause of grief or of the other depressing passions should supervene. The first effect of fever, which we shall find to proceed from a sudden debility of the sensorial power, has a similar effect. Van Helmont relates an accident that happened to himself, which will illustrate this opinion. He was going abroad to dinner, when, from accident, he dislocated his ankle. His appetite immediately left him; but was restored when his joint was replaced, though the pain continued for some time with little alteration.

When animals die for want of food, their death is not directly the consequence of hunger, but a putrid fever, which is excited by the blood's losing its bland gelatinous consistence, for want of the usual necessary supplies.

FA'MES CANI'NA. See **BOULIMUS**.

FAMIGERATI'SSIMUM EMPLASTRUM, (from *famigeratus, renowned*, from *fama, fame*, and *gero, to bear*). A plaster used in intermittent fevers, made of aromatic irritating substances, and applied to the wrists. It is thus named for its excellence.

FAR, (from the Hebrew word *var, frumentum*). **GRAIN**. It not only means a particular kind of grain, between wheat and barley, less nourishing than the former, but more so than the latter, according to Vossius; but it means bread corn, grain of any kind. Ætius gives this application to any kind of frumentaceous grain, decorticated, cleansed from the husks, and afterwards bruised and dried.

FARCIMINA'LIS, (from *farcimen, stuffing sausage, or hog's pudding*). See **ALEANTOIS**.

FARCTU'RA, (from *farcio, to stuff*), in pharmacy, the stuffing of any exenterated animal, or excavated fruit, with medicinal ingredients.

FA'RCTUS, (from the same,) crammed, or full: thus in botany *folium farctum* is a leaf full of pith or pulp; in opposition to *tubulosum* and *fistulosum*, tubular, like a pipe. It is applied also to the stem and pericarpium.

FA'RFARA, FARFARE'LLA, (from *farfarus*, the white poplar; so called because its leaves resemble those of that tree). See TUSSILAGO.

FA'RFARUS, (from a river of the Sabines on whose banks it grew plentifully). See POPULUS ALBA.

FA'RINA, (from *far*, corn, from which it is made). MEAL OF FLOUR.

FA'RINA FŒCUNDANS. IMPREGNATING DUST. It is placed on the apices of flowers, and falls on the head of the pistil or female part of the flower, and is thence conveyed to the matrix, in order to impregnate the seed.

FARINA'CEA, (from *farina*, flower). Under this title are included those substances employed as aliment, called *cerealia*, *legumina*, and *nuces oleosæ*, generally distinguished as they contain more or less saccharine and oily matter. Under the title *cerealia* we commonly find the seeds of several gramineous and culmiferous plants employed as food for men, viz. barley, rye, millet, rice, oats, maize, wheat, buckwheat, salep, chestnut, and potato. The *legumina*, or pulses, are the pea, bean, and kidney bean: which last are in this country only employed in their young, green state. The *nuces oleosæ* are the nut, almonds, walnut, pistachio nut; and some products of others, as chocolate. See CERREALIA and ALIMENT. Cullen's Mat. Med.

FARINA'CEUS PA'NIS. See PANIS.

FARINA'RIMUM, (from *farina*, flower). See ALICA.

FA'RINHA FRE'SCA, and RE'LADA. See CASADA.

FARNESIA'NUS FLŒS. See BATTATAS CANADENSIS.

FARRA'GO, corrupted from FAVAGO, q. v.

FA'RREA NU'BES, (from *far*, bran, and *nubes*, a cloud). See FURFUROSI.

FA'SCIA, *ligatio*, *ligatura*, *alligatura*. A BANDAGE, FILLET, ROLLER, OR LIGATURE. Of bandages, in general, we have spoken in the article DELIGATIO; and it now only remains to consider the different forms of bandages applied to particular purposes. The first of these is,

The sling, echarpe. This appellation is given to several sorts of bandages.

The sling with four heads should be four feet in length: the breadth that of six or eight fingers. Its use is to retain the dressing on the wounded head. It must be divided longitudinally, from each end, into two heads, so as to leave about two hands' breadth entire in the middle, and the four ends must be rolled up to where the division ends. Apply the middle of the undivided part upon the dressings; then tying the two posterior heads forward, and having secured their ends, the two anterior ends must be carried backward, and secured behind the head. This is sometimes called Galen's bandage.

The sling with six heads, periscepastrum, is about three feet in length, its breadth about twelve or fourteen inches. It must be divided from each end to within a hand's breadth of the middle, into three parts. Apply the middle undivided part to the vertex, and tie the two anterior tails behind the head, the two middle under the chin, and the two posterior upon the forehead.

The sling for the nose hath four heads, is eight feet long, and two or three inches broad. In the middle it is left entire, but from thence, each way, it is slit to

the ends. In the middle, where it is entire, an opening is made for the apex of the nose, that the bandage may be firm. The middle is applied upon the nose, the two upper heads to the neck, and then to the forehead; the lower ones behind the neck, but a little higher than the first, and to the forehead also.

The sling for the breasts is four feet long, six inches broad, and slit like the sling with four heads; about a foot in the middle being left entire. The middle is to be applied upon the dressings on the affected breast; then the two upper heads must be carried over the opposite shoulder, and the two lower under the arm of the affected side, towards the scapula of the other side: they must there be fastened to the upper ends which are over the shoulder.

The single bridle, capistry, is a single headed roller, fourteen or sixteen feet long, and two or three fingers broad, for securing the jaw when fractured or luxated. It is applied under the chin, and over the head; called by Galen *geneias*.

The double bridle is the same as the single, but rolled up with two heads: the single may, however, always be used instead of it. See CHEVASTRE.

Bandages for the lips, of a proper length and breadth, are formed as the sling with four heads.

Bandages for the eyes or eye lids. See MONOCULUS.

The divider for the neck is twenty-four feet long, two or three fingers' breadth broad, and is rolled into two heads. Its middle is placed on the forehead, and thence passes round the head two or three times. When secured with pins, the rollers are carried under each armpit, and brought back over the shoulders, and cross the neck in the form of an X. It is then passed on to the forehead, &c. until the whole is taken up.

The retentive bandage for the neck. Two distinct ones are usually directed, but one circular roller answers every useful purpose. When two bandages are employed, one is a fillet about two feet in length, laid across the head so as to hang down on the shoulders. Over these ends another fillet, five or six feet in length, and nearly three fingers broad, is rolled circularly round the neck. The ends of the first fillet are then doubled back, and secured to the circular turns by pins.

Divisive bandage, to support the head, consists of a fillet laid over the head, so as to fall on the forehead and low on the neck. Another fillet, eighteen feet long, and about the breadth of three fingers, is rolled on two heads. The middle part of this bandage is applied over the fillet on the forehead, carried over the ears, round the head to the back of the neck. Its heads are then crossed, brought under both axillæ, carried backward over the shoulders; crossed again, and carried under the axillæ over the breast. The heads are again shifted, and the remainder rolled with circular turns. The hanging ends of the first small fillet are then turned back over the head, and fastened by pins to the turns of the bandage.

The uniting neck bandage consists of a napkin under the axillæ, to which fillets, fastened to the nightcap, are pinned, to keep the head steady, when placed in the proper position. It is used in wounds of the neck or trachea.

The inguinal bandage, for luxations of the thigh, is only the common roller, eight or nine yards in length, and about four fingers broad.

The *napkin* and *scapulary* are used when a bandage is required on the breast, belly, or back. It consists of a napkin pinned round the body, where the disorder renders it necessary; and, to prevent its falling, the *scapulary* is applied, viz. a piece of linen, four or six inches broad, with a slit in the middle for the head to pass through; its length sufficient for one end to be pinned to the napkin behind, and the other end to the napkin before. The *scapulary* is sometimes fastened behind, and the other end slit far enough to bring each part over the shoulders to be fastened before.

FA'SCIA. See APONEUROSIS.

FA'SCIA LATA is a large, membranous, tendinous, or ligamentary covering. Winslow describes it as a muscular ligament, fixed about the edge of the crista of the os ilium, from the large tuberosity, to the anterior superior spine, to the ligamentum Fallopii, and to the aponeurosis of the oblique external muscle of the belly. It is also fixed to the lateral inferior part of the os sacrum, and to the neighbouring part of the ligaments by which that bone is connected to the bones of the ilium and ischium. From thence it advances over the glutæi and thigh, between the membrana adiposa and muscles, to the interior and outer part of the knee; over the external anterior part of the tibia, and is strongly inserted into the head of the tibia and of the fibula. It is inserted also firmly into the linea aspera femoris, between the vastus externus and biceps, forming a sort of septum between these muscles. See APONEUROSIS.

FA'SCIA LATA MUSCULUS rises from the outside of the ilium, runs downwards and outwards; and, below the trochanter major, joins with the tendons of the glutæus maximus, and runs down laterally to the leg. This muscle stretches the fascia lata above described, and on this account Albinus calls it *tensor fasciæ femoris*.

FA'SCIA LATA LUMBO'RUM is a strong tendon fixed to the lateral part of the os sacrum, from the spines of the sacrum, from the spine of the ilium, and the spines of the lumbar vertebræ.

FASCIA'LIS, (from *fascia*, a ligament). See SARTORIUS.

FASCICULARIS, (from *fasciculus*, a little bundle). In botany it means tuberos, or having the knobs of the roots collected in bundles, as in the pæony.

FASCICULATUS, (from the same,) in botany, leaves growing in bunches, as in the larch tree.

FASCICULUS, (from *fascis*, a bundle). A kind of inflorescence, in which the flowers grow close to each other, forming a flat surface, as in the sweet-william. See MANIPULUS.

FASCIO'LA. A flattish round worm, called the *gourd worm*, from its resemblance to a gourd seed; and the *fluke*, from its resemblance to a worm found in ditches, is distinguished chiefly by a vent hole at the extremity and on the belly. A worm of this kind is found in the liver, sometimes nearly an inch in its longest diameter, and about two thirds of an inch in the shortest. It is rounded on the back, and has eight deep longitudinal furrows in two series. The skin is soft, and in colour of a light brown. It is most commonly found in the livers of sheep which have the disease called the rot, and sometimes in the human liver. Another species is found in the intestines of the bream, and some other fresh water fish. It is of an oval form; but may

be extended to some length. One other, the *barbata*, is white, and found in the intestines of the cuttle fish.

FASTIDIUM CIBO'RUM, (from *fastidio*, to loath). LOATHING OF FOOD. Some barbarous writers, for this term, use *abominatio*. See APEPSIA.

FASTIGIATUS, (from *fastigium*, the top or roof of a house). In botany it is applied to the stalks when they grow so as to form the appearance of the ridge of a house.

FATIGUE. See COPOS.

FATUITAS, (from *fatuus*, foolish, insipid). Insipid aliments were called by the Latins *fatui*, whence the term is applied both to foolishness and unsavouriness. In Cullen's Nosology it is synonymous with *amentia*. See also MOROSIS.

FAUCES, (the plural of *fauz*, the top of the throat,) *isthmion*, *amphibranchia*. The top of the throat; the space about the openings into the larynx and pharynx, which can be seen when the mouth is open and the tongue depressed. Upon looking into a person's mouth when wide open, we see a soft curtain hanging from the palate bones, named *velum pendulum palati*; in the middle of which a papilla projects from the velum, named *uvula*, or pap of the throat. From each side of the uvula, at its root, two arches or columns pass down, the anterior to the root of the tongue, the posterior to the entrance of the gullet. Between the arches, on each side, the cellular glands, called *amygdalæ*, or almonds of the ears, are situated. The common opening behind the anterior arch may be named *fauces*, from which there are six passages, viz. two upwards, one to each nostril; two at the sides, or one to each ear, called the *Eustachian tubes*; two downwards: the anterior is the passage through the glottis and larynx into the trachea, which terminates in the lungs; the posterior is the largest, named *pharynx*, or the top of the œsophagus, which leads to the stomach. Innes on the Muscles.

FAUFEL. See ARECA; also TERRA JAPONICA.

FAUX. In botany it means the hiatus of the tube of the corolla. See FAUCES.

FAVAGO AUSTRALIS, (from *favus*, a honeycomb). A species of BASTARD SPONGE, like a honeycomb. See ALCYONUM FARRAGO.

FAVUS. A HONEYCOMB. See ACHOR.

FEBRIFUGA. FEVERFEW, (from *februm fugare*, to drive away a fever). See MATRICARIA. Such medicines also as mitigate or remove fevers.

FEBRIFUGUM OLEUM. FEBRIFUGE OIL. The flowers of antimony, made with sal ammoniac and antimony sublimed together, and exposed to the air, when they deliquesce.

FEBRIFUGUS PULVIS CRE'NIÏ. See ANTIMONIUM.

FEBRIFUGUS PULVIS. FEBRIFUGE POWDER. The Germans give this name to the stypticus pulvis Helvetii. In England a mixture of oculi cancerorum and emetic tartar, in proportions of half a drachm and two grains, hath obtained the same appellation; in fevers it is given in doses of gr. iii. to iv.

FEBRIFUGUS SAL, i. e. SAL MARINUS REGENERATUS. See MARINUM SAL.

FEBRIFUGUS SPIRITUS DO'MINI CLU'TTON. MR. CLUTTON'S FEBRIFUGE SPIRIT.

Take the oil of sulphur, by the bell, and rightly prepared, rectified oil of vitriol, and spirit of salt, of each

equal parts; and of rectified spirit of wine, triple the quantity of the whole. Digest them together for a month, then distil to dryness.

In some receipts, common salt is inserted instead of spirit of salt, which will make little difference in the result. The whole, however, is an imperfect ether, and may be imitated by adding any proportion of the muriatic acid to the sweet spirit of vitriol.

As much of this spirit as renders pure water agreeably acid is sometimes given in every draught of common drink in ardent and inflammatory fevers; and in those of the nervous and putrid kind it is administered in cordial and antiseptic liquors. We have sometimes employed it, though without any marked advantages. See the Certain Method of curing all continued Fevers, by Jo. Clutton.

FE'BRIS, (from *febreo*, pro *ferveo*, to be hot). Since the complaints of mankind have attracted the attention of practitioners, the cause of fevers has been a problem that they have in vain attempted to solve; and even the disease itself they have not been able to discriminate by any constant pathognomonic symptom. From the etymology of the term, its essence is supposed to consist in heat; but the skin is sometimes cold: in quick pulse; but the pulse is occasionally slow: in preceding horror; but such a symptom is often unobserved or absent. Critical pathologists have filled pages with such (we think idle) disquisitions; but every physician has been able to distinguish fever by at least some of these symptoms, or a comparison of the different ones; and, among the innumerable mistakes and blunders that we have witnessed, we believe in no one instance has error been found to arise from mistaking fever. Within this fortnight we saw a woman of 82, generally allowed to be in a fever; but the pulse was only 70, the skin cool, the countenance apparently unchanged: it was, however, easy to perceive, from the peculiar feel of the pulse, that it was in a morbid state, and the skin of the palms was tense. She recovered rapidly, the pulse sunk to less than 60, the skin became more genially soft, and the appetite returned.

Dr. Cullen establishes a class of febrile diseases which he styles *pyrexia*. The symptoms assigned are, "after chilliness, a frequent pulse, increased heat, several of the functions of the body injured; the strength of the limbs particularly diminished." Fever, more strictly, is "pyrexia, with preceding languor, lassitude, and other signs of debility, without any local disease." Dr. Fordyce, though he has refined too much, and raised imaginary difficulties in the application of every definition of fever, has, however, shown that these symptoms will not entirely and completely distinguish febrile diseases. One almost constant symptom may be added, a tension of the tendons of the wrist; and we are fully of opinion, with Dr. Fordyce, that in every fever there is some mental alienation. If these two symptoms are added, the definition will be as complete as the most minute pathologist would require. The distinction will be, however, assisted by a more full description of the symptoms.

Previous to the attack of every fever, if it do not come on during sleep, or the attention is not directed very strongly to some interesting object or occupation, languor and debility are felt, with a sluggishness in motion, and some uneasiness in attempting it. The

face and extremities become pale; the features sunk: the bulk diminished; and the skin appears as if constricted by cold. Cold now comes on in the back, as if cold water was running down it, and soon extends over the whole body; though, in some instances, the patient will feel to another person warm. The cold increases to tremor; and this to rigors and shiverings, almost convulsive. Even at this period, the mind is unsteady and confused; attention and recollection are difficult; and stupor is sometimes an early symptom. The pulse becomes weaker, and even sometimes slower, than before; but as the cold increases, it is *always* smaller, and *almost constantly* quicker. The respiration is, at this period, small, frequent, and laborious; appetite ceases; a nausea, sickness, and vomiting, come on; and, at last, the matter discharged is highly bilious. The secretions are, in general, checked; the urine is watery; the mouth dry and clammy; ulcers no longer discharge; and tumours diminish or disappear. In the cold stage, frequently, though more often in the hot, headach comes on; but a constant symptom, though not sufficiently noticed by pathologists, is wandering pains over the whole body. Pain in the back is generally mentioned; but pains are felt in every joint, seldom continuing in any one part, but disappearing and returning. They are not sharp and pungent, but tensive and dull; evidently connected with the tension of the tendons, chiefly distinguished at the wrist. A striking change takes place in the features. In general they appear to be sunk; but this description is by no means sufficiently precise. It has not been with accuracy noticed how greatly the appearance of the features depends on the state of the mind: it is the latter which gives character, and a different effect to features otherwise similar. It is sufficient in this place to remark, that the change in the countenance is the absence of all characteristic impression, a vacant stare, accompanied with a kind of insensibility. This attends fever so often, or rather so universally, in every stage, that the existence of the disease may be thus known in a moment by a practitioner of even slight experience.

The continuance of the cold stage is uncertain. The coldness previous to the shivering is, in the worst fevers, of long duration, and the shivering slight. In general the shivering soon comes on; and after a time, different in almost every case, it seems to remit or alternate with slight flushings. In this interval we have thought, by our own feelings, that the disease had disappeared; and we have even remarked that the powers of the mind have, for a short period, returned. The scene, however, soon changes. The alternate flushings become violent heat; the skin again fills; the face becomes turgid; the mind again confused, and this confusion often increases to delirium; the pulse becomes more regular, hard, and full; the respiration more free, but still frequent and anxious; the thirst increases; the vomiting abates; the urine becomes of a deep red, and gives pain in the discharge; tumours again enlarge; and pus flows from ulcers. The sensibility is recovered, and often increased; the headach becomes excruciatingly violent.

After an uncertain period these symptoms abate. Sweat gradually breaks out, and soon becomes profuse. The urine deposits a copious sediment, all the painful symptoms disappear, and health is apparently

restored, with the exception only of some remaining debility.

These are the phenomena of fevers in their acute, regular, and distinct form. In intermittents they appear regularly, nearly as described; and the most perfect undisguised form of fever is the tertian. In remittents these various changes are less distinct; but the chief difference consists in the termination: the sweat is inconsiderable, and the relief imperfect, though the exacerbation is generally distinctly marked. In hectic the whole stage is often regular, and the intermission tolerably perfect; but the remaining state of debility very considerable. In continued fevers the exacerbations and remissions are indistinct; but an attentive practitioner will generally, we believe always, discover them. Like critical days, they require a minute examination for their detection; a minuteness of discrimination which some do not possess; an acuteness which others will not exert.

These three stages are evidently connected; and Dr. Cullen thinks, with great reason, that they are the causes of each other. In every fever each is probably present, though not always observed. The immediate cause of these very singular appearances, physicians in every period have been anxious to discover; but to collect all the theories, all the absurdities, which the imagination has suggested, would extend our article very far. In justice, however, to some of the ablest of our predecessors, we shall notice a few of the principal opinions.

When a violent commotion was observed in the system, followed by an evacuation from the skin and the kidneys, it was an obvious conclusion that something noxious had been introduced, which, at the conclusion of the paroxysm, was discharged. The opinion was at least innocent, if not ingenious; but when to this first idea was added, that the morbid matter was prepared for expulsion by the febrile commotion, and particularly the hot fit, the opinion produced the most fatal consequences, as it led to every means of increasing the heat, in order to assist this unknown process which the morbid matter was to undergo. The simplest observations were couched in the language of this theory; and when, for instance, the authors had observed that, during the violence of the heat, it was injurious to attempt forcing any evacuation, they told us, that *cocta non cruda sunt evacuanda*. Many of the aphorisms of Hippocrates, which have thus a profound scientific appearance, are only the commonest remarks in the jargon of a system.

As it could not escape the most superficial observers that, after an apparently complete solution, the disease returned, this morbid matter was supposed not to be wholly discharged; but the little remains possessing an assimilating power, was augmented in quantity, till it was again sufficiently powerful to reproduce the paroxysm. At last, either by superior exertion, or some unknown cause, it was wholly evacuated, and health restored. In support of this, they usually found, what is indeed true, that the last paroxysm was the most violent.

The theory was certainly highly probable; but, as if impregnable, succeeding authors attempted only to proceed another step, and the morbid matter was acid, alkaline, earthy, inflammable; for a time any thing which the predisposing causes could in the slightest degree

support. At last Boerhaave supposed it no foreign substance introduced, but a lentor or viscosity in the blood itself; and it was no little triumph that the inflammatory crust on the blood was found peculiarly dense. In the latter period of his life, he wished to introduce a similar density, or rather inactivity, into the nervous fluid.

The various theories respecting the nature of this matter, each of which is supported with equal plausibility, would immediately lead us to conclude that no such exists; for, after the lapse of near three thousand years, it would be singular if some lucky conjecture had not supplied what investigation was inadequate to, and revealed the secret. In reality, however, there is no real evidence of any such morbid cause. The discharges are the usual ones; the pus of abscesses, when such is the termination of fever, displays no peculiar qualities; the blood, which in other cases apparently relieves the fever by flowing from the nose, is equally pure with that taken from the arm. That it is concocted or meliorated by the hot fit is less probable; for if from the hot fit of fevers any change is produced on the fluids, it is of a kind perfectly different; nor is there any similar process in any part of the animal economy. We find that fevers may be often checked in their attack, without waiting for this process; and by mitigating the heat, the supposed great agent in producing this change, we cure the fever more quickly and more safely.

Any change in the physical qualities of the blood is wholly gratuitous. It has been examined by every test, and all its properties are found with scarcely any alteration. The buffy coat is now known to be owing chiefly to a more perfect state of mixture of the incongruous portions of the blood rather than viscosity.

Allied to these systems is an equally dangerous error, that fever is a cure of other disorders. Intermittents have been considered as such; and a practitioner of the Boerhaavian school is said to have asserted, that if he could produce a fever as easily as he could cure it, he should be well satisfied with his own skill. Luckily for his patients, this power was denied him; for we know no disease, which, if at all within the reach of art, may not be at least as soon and as perfectly relieved without its assistance.

A later opinion has been, that fever is heat only; and to be cured by its opposite, cold. Cold undoubtedly mitigates the increased action of the sanguiferous system, and if it does not cure, greatly relieves fever. Like the best of our remedies, it contributes to conduct fever safely to its termination; but we receive no information from this system respecting the cause of the heat, or its connection with the other symptoms.

While the system of Boerhaave prevailed in the south of Germany, different views arose in the north. The patient and industrious Hoffman thought he saw in fevers a change in the state of motion, and an inaction, which he styled a spasm (*spasmus periphericus*), in the extreme vessels. His colleague and rival, rather than his enemy, Stahl, carried the idea further; and gave some sufficiently distinct views of altered determination as the cause of many disorders. The former, however, deeply immersed in the chemical pathology, though he decidedly referred all diseases to altered motions and the state of the nerves, gave no fixed determinate system of pathology on this foundation, but intermixed these ideas with the different kinds of chemical acri-

mony; and the latter involved it so deeply in a logical form, and mixed it so intimately with his peculiar metaphysical doctrines, that they have hitherto escaped notice, and will not probably again engage the pathologist's attention.

As the symptoms of fever are so exclusively nervous, and as the vital power is so particularly affected, it is singular that they should not have been at once referred to the nervous system, and its peculiar animating principle. Dr. Cullen, taking the hint certainly from Hoffman, started, as usual, into a track at once bold, comprehensive, and original. The cold stage he considers as the source of the subsequent phenomena; and this he supposes owing to debility. A state of debility is evident, he thinks, from the previous symptoms of languor and lassitude; and occasioned by some sedative powers, which are the more remote causes of fevers. These diminish the energy of the brain and the whole system, particularly of the extreme vessels in every part, inducing the symptoms of the cold fit, and a spasm on these vessels. This spasm excites the action of the sanguiferous system by the intervention of the vires medicatrices naturæ, thus restoring the energy of the brain, and overcoming its cause. The discharge of sweat, and the relaxation of all the excretory vessels, are the consequence.

One great defect in this system, which we shall first notice, is, that the return of the paroxysms is not accounted for. Debility confessedly precedes; but, according to this doctrine, the debility is conquered. The return can only be explained then by the cause continuing to act. When this is a material one, as marsh miasmata or contagion, the reason may be admitted; though it militates against a succeeding opinion of Dr. Cullen, that, when once the disease is produced, the influence of the remote cause ceases. When, however, the cause is not material, when the fever is excited by emotions or passions, the explanation will not avail; but this subject we shall resume.

In this system the production of spasm by debility is an isolated fact, without a support; and the introduction of the vires medicatrices naturæ is the interposition of a divinity in an epic, when no probable resource is at hand. Yet each may be perhaps easily reconciled by a little change.

Dr. Darwin's explanation of fever is less distinct. He considers the causes as producing a quiescence of the arteries, and the subsequent heat as an exertion of the sensorial power, in consequence of accumulated irritability. We have admitted this author's principle of accumulated irritability; but have some doubts whether it is applicable to this purpose. From the language and the illustrations we can expect no further increase than we have found of previous diminution; no more can be collected than has been lost: but what proportion does the very few hours shivering bear to the burning heat of seven days, during which the shortest inflammatory fever continues? Added to this, at the end of fever we find every symptom of exhausted irritability, as if not only the accumulation was expended, but the former stock diminished. Again, in every case of accumulated irritability, some time is required for the temporary repression. In the human body it is accumulated, but in no extraordinary degree, after some hours sleep; in some animals after the torpor of a whole winter; on captain Bligh's crew, after weeks of abstinence and con-

finement. These facts bear no proportion to the shortness of the cold fit, compared with the continuation of the heat; and, though it be admitted in a certain degree, it must be with some modifications and explanations.

We have often hinted that we differed in some respects from Dr. Cullen, and shall now state what we think a more probable view of the subject, connecting, in some measure, both the opinions just stated. Not the slightest doubt can exist but that the first symptoms of fever are those of debility—of a debility of the sensorial power, in other words, of the energy of the brain. This may arise from actual or from partial debility, occasioning an unequal excitement in different parts of the brain, which seems to produce the same effects. Under the article CONVULSIONS, and other places, we have endeavoured to show that either real debility or unequal excitement is the cause of irregular action of the muscles; and this appears in the tremors and rigors, and in the spasm of the capillaries, not only of the surface and glands, but of every other organ. The irritability thus accumulated may occasion the exertion of the sensorial power; but the heat, for the reasons assigned, is not wholly owing to this exertion. In fact, the greater activity of this power, or of the vires medicatrices, implies increased energy; but through the whole course of fever we see only debility, and its consequence, irregular action. Even the boasted sensorial power is weakened, or irregularly exerted; and while the sanguiferous system acts with vigour, the voluntary muscles and the brain show every mark of diminished energy. There is then no contest between these rivals, the spasm and the vires medicatrices; but the debility continues, though varied in its form.

Obstruction to the circulation increases its activity; for the vessels are excited by distention, and, when the extent of the circuit is curtailed, those behind act with greater energy. Thus tying up the finger will bring on inflammation in the whole hand. While, then, the accumulated irritability first excites the sensorial power, the spasm contributes to accelerate the circulation; and, in the weakened state of the brain, this increased action diminishes the nervous power in other parts of the body. The paroxysm is closed by the spasm relaxing, since there is no instance of continued spasm, except by continued irritation; and the spasm relaxes at different periods by the laws established in the system, which we explained under the article DIÆTA. It is a fact, that fevers attack at the periods of the regular exacerbation, and yield at the times these constantly regular paroxysms are resolved. Every paroxysm is either resolved or remits at the end of twenty-four hours; the diurnal revolution, established by the regularly returning periods of sleep and watching; the discharge of the alvine excretions, of appetite, &c. It is not so easy to assign a reason why, in a fever consisting of successive paroxysms, the disease should yield only at a given time; except that a septenary period prevails, at the end of which the solutions of the usual exacerbations are more perfect. Of this, however, we have no certain evidence.

It appears singular that increased action should ever have formed a part of the theory of fevers. It is obvious in the sanguiferous system; but the opposite state is singularly conspicuous in every other part. Even when in delirium, the voluntary muscles are, for a time,

violently exerted; it is the energy of a moment, generally accompanied with tremor, and succeeded by the most considerable debility. A tone, an apparent temporary strength, is seemingly kept up by fever, as greater weakness is felt at its solution than during its course. But it can only be said, that, if the debility is in excess afterwards, it is considerable while the disease continues; and this apparent tone is evidently kept up by the increased action of the vessels in the brain, from which also the delirium proceeds. In short, after watching fevers with attention for thirty-five years, we have never seen any appearance of increased action, except in the sanguiferous system, and even in these vessels the circulation is not apparently free.

It has been objected to the doctrine of spasm, that sweats are sometimes copious. Undoubtedly, at the first view, the argument seems invincible. Yet, if we examine fevers, we shall usually find the skin dry and hot. If we press the palms of the hand, though the hand appear otherwise cool, a heat will be felt there: and the impression communicated to the fingers is not the soft unctuous feel of the healthy skin, but the harshness of dry parchement somewhat warmed. In the profusest sweat, excited by stimulants, the same sensation is perceptible; and as we find this so constantly in fevers; as we find, too, that such sweats not only do not relieve, but add to the oppression, while the soft healthy perspiration is attended with freedom and cheerfulness; we have been led to think these cutaneous evacuations arise from different sources. We have pointed out the distinction under the article *DIAPHORETICA*; but whatever be the opinion formed of it, the proper perspiration certainly does not come on till the solution of fever, and it is equally certain that sweating does not supply its place.

The objection that debility is not a cause, since great debility often occurs without fever following, is of still less importance. In this case the sensorial power is affected; the energy of the brain is lessened. In hectics, in drosy, and in the various nervous diseases where the debility is very considerable, the vital and animal functions only suffer: the mind remains free and unaffected. In fever, the alienation of mind occurs in the first attack; and it is remarkable that in hectics the mind only suffers during the paroxysm.

The principal effect of this state of debility, independent of the irregular action, which is its most constant consequence, appears to be the altered determination. The fluids are confined to the larger vessels; and as the veins, which, by their union, form the *vena portæ*, have no power of impelling the increased load, it is chiefly felt in the liver. We pointed out also the apparent anxiety of nature to keep the vessels of the brain in a state of sufficient tension, and the structure of the sinuses adapted for this purpose. It will be obvious, from these considerations, that the head also should largely share in this accumulation. These circumstances should be kept fully in view, as they are of the greatest importance in practice. From debility, then, and an altered determination, or, in other words, from a change in the balance of the circulation, all the appearances in fevers may be deduced. When, at the conclusion, an apparently putrid dissolution of the blood takes place, it is owing to a diminution of the principle

of life, which alone prevents the usual changes of dead animal matter taking place in the living system.

When fevers were supposed to consist in increased action, the REMOTE CAUSES were sought in stimuli of every kind; but if stimulus would alone produce fever, exercise and heat would be its most frequent causes, and common language might be safely transferred to science. But if the effects of exercise and heat are fevers, fever is not a disease; for the warmth and accelerated circulation produce no inconvenience, no function is injured, and, with common precautions, they disappear without the slightest inconvenience. More attentive observation has shown the remote causes to be *contagion*, and the *effluvia from marshes*; nor do we distinctly see the exclusive operation of any other, at least of very few others.

Contagion, in this place, has a very extensive meaning. If many men are confined in a comparatively small place, their health is gradually undermined; their complexions become sallow; their appetite and spirits fail. No real disease may be observable in them; yet, to others, they will sometimes in this state communicate fever, and fever will appear to arise spontaneously among themselves. We see that this poison undermines the springs of life; and though its gradual increase accustoms its action, yet in another it will produce the disease. When the fever is actually formed, it is well known that it may be communicated by its effluvia. Another kind of contagion produced in the body, is that of purulent matter absorbed from an abscess. This we know from its effects to be of an highly sedative nature; and we have much reason to think that it may, in some cases, be communicated to others by effluvia.

There are various peculiar and distinct contagions, which excite fevers of a particular form, attended with cutaneous affections. The jail and hospital fever may be considered as the consequence of a peculiar contagion; but no cutaneous inflammation is the consequence. The plague connects this with the other exanthemata; but in each the prior appearance of fever, often with peculiar marks of debility, shows that the virus is of a sedative nature. The profluvia of Dr. Cullen also arise from contagious effluvia peculiarly their own.

The *effluvia from marshes* is now fully ascertained to be a remote cause of epidemics, and of some of the most destructive debilitating kinds. Their sedative tendency is, therefore, sufficiently obvious; and, as they probably consist of hydrogenous gas, which destroys the irritability of the fibres, its real nature may be easily understood. Marshes covered with water are not injurious; but when the earth begins to appear above the water the epidemics commence.

Bile has been enumerated among the remote causes; but its appearance may be easily accounted for from the explanations already given. When we know it to be diseased, either in quantity or quality, symptoms very different from fever arise.

Putrid vegetable substances have been supposed to exhale effluvia injurious to life, and to be particularly active in producing the worst fevers. This we believe to be sometimes the case; but they more frequently give some peculiarity to the nature of the fever, rendering it more asthenic or putrefactive.

Cold is undoubtedly also a remote cause; but in producing fever it must be actively applied while the body is heated, and the effects can only be considered at length when we treat of inflammation. It is, however, especially when united with moisture, an exciting cause. See CAUSA, COLD, and CONTAGION.

Fevers, from a variety of circumstances often not easily explained, assume many different forms. Every fever seems to consist of distinct paroxysms, almost universally concluded within twenty-four hours; and the existence of a *continent fever*, one which proceeds without any changes, is not at present admitted. To the termination of each paroxysm within twenty-four hours there have been some objections; but the fallacy arises from the existence of double tertians, or the combination of two kinds of intermittents. In these cases the cold fit of the second disease sometimes attacks in the middle of the hot fit of the former, and thus in appearance protracts the paroxysm. Many such instances are recorded by Torti and Senac.

Fevers, then, may be *divided* into those which have distinct paroxysms, and those in which the accessions and terminations are less distinct. The first include the INTERMITTENTS and REMITTENTS; the second the CONTINUED FEVERS.

The symptoms of intermittents are the regular paroxysms, which we have described. When these degenerate into remittents, the cold fit becomes shorter, and is less distinctly marked; the heat is less considerable, and longer protracted; the sweat comes on; but before the complete termination another attack supervenes. In the more continued forms we lose the attack, and in some degree the solution, by sweat. We find only occasional exacerbations of heat, and remissions in which the pulse is more soft and full; the hands cooler and more moist.

In every attack of a continued fever we find, in the commencement, apparent remissions, particularly in the morning. The day passes with tolerable ease; the patient thinks his disease at an end, and the physician flatters himself that he has been too soon alarmed. The succeeding evening, however, ends the delusion, and each following morning the remission is less distinct; though on every morning there is usually a visible amendment.

In the early state of a continued fever there are often wandering pains, which have been considered as rheumatic; and we suspect have occasioned the nosologists to introduce the genus *synochus*. These pains are apparently often the tensive ones, which we have attributed to irregular action; but they are undoubtedly sometimes rheumatic, and have occasionally, as in one of the epidemic nervous fevers described by Sydenham, attacked the chest, with pleuritic or peripneumonic symptoms. Much inconvenience has arisen from this symptom, since it has led to bleeding in fevers of the worst tendency. We recollect, indeed, but one epidemic in which similar pains were wholly absent, and this was a malignant remittent at Breslaw, described by De Haen, on the attack of which, even previous rheumatic pains disappeared.

When these symptoms no longer occur, continued fevers proceed many days, with little change. Symptoms of debility, to be described by the prognosis, in-

crease; the head becomes more loaded; the patient more insensible, or more delirious; the character of the features is lost, or they are enlarged so as to disguise every former appearance. The pulse becomes more quick; the abdomen more distended; stools at times less frequent, but occasionally numerous, watery, and involuntary; the tendons of the wrist more tense, and sometimes starting with a convulsive motion. The tongue, at first brown only in the middle, is dry, furred, and of a dark red or a livid colour. Its action is lost, and the patient can either not put it out, or it is pushed forward with an unequal, tremulous exertion. The edges, which for some time continue moist, are at last equally dry with the rest; and, for examination, it must be drawn by the fingers beyond the teeth, and replaced. The inability to swallow keeps pace with the changes in the tongue, and at last the power of deglutition is wholly lost. The insensibility increases; the starting of the tendons is followed by convulsive catchings; the patient attempts to pick off some objects from the bed-clothes, then sinks into insensibility, from which he is only roused by the last convulsive struggles.

This is a faithful picture of the general progress of continued fever, either fatal from its violence, from neglect, or from improper treatment. In more favourable circumstances, or with proper management, the head is less loaded; the tension of the epigastrium is inconsiderable; the tongue continues clean at the edges; some refreshing sleep is obtained every day; and, about the fourteenth, after an unusually restless night, sleep more sound and natural occurs; the pulse becomes softer and slower; the edges of the tongue appear of a more healthy redness; the palms of the hands more moist; the recollection clearer. Sometimes these changes are very gradual, and the experienced practitioner perceives them two or three days before they are conspicuous to the attendants. It is not uncommon to find the first appearances of returning health in a whimsical capricious appetite. The patient wishes for something savoury. If brought, it is rejected with disgust. The next object may be more singular, and this may be tasted; a small portion of the next is perhaps swallowed. In other instances, some particular food, very frequently that least pleasing when in health, is eagerly longed for, and as voraciously devoured, without injury. In general, to long for a particular food is a favourable symptom, and a certain proof of returning health.

Intermittents and *remittents* arise from the same causes, are relieved by the same remedies, and pass into each other. In the former the intermissions are distinct, and no inconsiderable period intervenes in which the patient is free from fever; but on some occasions, from different causes, this period is considerably restricted. Double intermittents, in the circumstances just assigned, often assume the form of remittents; but the error which this confusion would occasion will produce no practical mischief.

It is a general fact, that the longer the paroxysms are protracted, they are sooner repeated; as well as that the access and the fever are violent, in proportion to the shortness of their duration. From this universal law, it is easy to see how intermittents, particularly quotidian, become remittents, and, in their progress, continued fevers. Dr. Cullen explains the variety by the proportional

strength of the opponents, spasm and reaction, in different circumstances. It seems to us to depend rather on the weakness of the cause. The fever comes on with the usual diurnal period of febrile exacerbation, remits with its decline, and disappears on its solution. There is, however, a regularity which is not easily explicable. The quotidian attacks with the morning exacerbation, the tertian with the noon, and the quartan with the evening. Are these diseases of different violence in the same order? There is no other evidence of such an opinion than this, that the quotidian is in general the milder, and the quartan the more obstinate disease; but the appearance of each, in distinct epidemics, is so striking, that there is little dependence on such reasoning, and we must leave it with the numerous arcana of the medical science.

Remittents, we have said, are diseases in every respect similar to intermittents, except that fever is never wholly absent; yet there is one remittent which nosologists have reluctantly admitted, and one which, in a natural system, imperiously demands admission: the first is the irregular intermittent or remittent, the erratica, and the second the hectic. So far as we have been able to investigate the former, it is only an irregular hectic, either from visceral obstructions, or from absorbed matter; and the latter is well known to proceed from the absorption of pus.

The continued fevers are probably quotidians only, with protracted paroxysms. In these what is styled reaction is not considerable, and this certainly proves an increased action of a debilitating power; in other words, the introduction of a more deleterious poison. The worst fevers are introduced by the longest cold, and the mildest by the most violent rigors: a circumstance which leads Dr. Cullen to conclude, with great apparent reason, that the rigor is an effect, probably a measure, of the reaction. Perhaps the explanation is nearer the surface: the reaction is in proportion to the irritability; and a powerful debilitating cause will not only weaken the sensorial power, but impair the irritability also. We have decisive evidence of the truth of this explanation, since those who die rapidly from fevers have the irritability of the muscles destroyed as completely as those who are struck by lightning. On the opposite side, it does not appear that the diathesis phlogistica greatly increases the spasm, since the true inflammatory fevers are the shortest. Irritability, we know, is not in proportion to the inflammatory diathesis; and we should not, from our views, suppose such fevers peculiarly obstinate.

We are unwilling to admit any other variations of simple fever, since those introduced by medical authors seem to be only accidental varieties. Indeed we consider fever as a more simple disease than it is usually represented; and shall endeavour to show, that what are termed genera are only, in a strict systematic view, species, and the reputed species, varieties. But these considerations must not now interrupt us. The principal distinctions, in the best works, have been into *bilious* and *putrid fevers*; the former comprehending the yellow fevers in all the variety of denomination; the latter the malignant, the petechial, &c. &c. The bilious fevers are, however, those of the tertian type, distinguished by evacuations of bile, from the causes formerly explained; and the autumnal remittents of warm climates. The putrid fevers are the worst kinds of the jail and hospital

fevers, where the deficiency of the vis vitæ no longer checks the tendency of animal substances to putrefaction; and where, in some instances, even a septic ferment may be suspected.

The prognosis of fevers has occupied many volumes. We can give only the outline. Consistently with the views offered, our prognostics must be taken from the signs and degree of debility, or the diminution of irritability. When Dr. Cullen endeavours to anticipate the event by the degree of reaction, he betrays the weakness of his system, as this state affords few prognostics, and those rather to be attributed to debility. When congestions in the head or in the lungs, for instance, occasion effusion or rupture, these only occur in the last stage of a protracted disease, though attributed by him to the violence of reaction.

Our prognosis must then be taken from the degree of debility. This is obvious often to the sight: and the young practitioner should exercise his acuteness by careful and attentive observation at the bedside. Every circumstance which regards a patient in a fever will give him information. The situation of the patient is dangerous, if the character of the countenance is soon lost; if the eyes apparently glare on vacancy; if the answers are rambling and incoherent; if slight, partial, involuntary contractions occur in the features; if the tongue trembles, or is soon dry and dark; if he soon declines turning on his sides, lies on his back, and sinks down on his bed; if the extremities are cold and benumbed; if the tendons are particularly tense, and occasionally start; and if he appears to pick off or remove any dark spots on the bedclothes, or wishes some supposed dark object to be removed. Each of these symptoms is a mark of debility; and the earlier they occur in fever, the danger is greater.

In the vital functions there are many marks of considerable debility, which prognosticate a dangerous disease. These are a very quick, low, intermitting pulse; frequent faintings, particularly on being raised to an erect position; short and inefficient respiration. The frequency of the pulse is relative, and the degree which denotes danger uncertain. An irritable female will often, from the beginning, have a pulse from 108 to 120; and the pulse of a very old person, in a dangerous state, may not exceed 80. If, however, in the first eight or ten days of a fever, the pulse exceed 112, there is danger, unless the constitution be otherwise irritable. If, at any period, it exceed 120, serious apprehensions of the event may be entertained. If it strike the finger weakly, and can be stopped by a slight pressure, it is a mark of great debility. On the contrary, a weak pulse will be sometimes apparently strong. It seems to throb, or the artery, on its dilatation, hangs reluctantly on the finger, as if unwilling to leave it; and the apparent strength of the impression appears to be caused by irritation. This is a state, however, only to be learned by experience; and we would recommend the most careful attention to the state of the pulse in every period of fever, not the mere number counted by the stop watch. This is a little parade of which young physicians are fond; but the experienced practitioner discovers more in the peculiar beat of the artery than any watch will convey.

In the natural functions, the symptoms which show considerable debility are sickness and vomiting; a dif-

faculty of deglutition; and involuntary discharges. Of these the vomiting is least dangerous; and difficult deglutition most so. Involuntary discharges we have known to continue for more than a week, and the patients have recovered. Sometimes deglutition is difficult, merely from the state of the tongue, which is occasionally hard, shrunk, and immovable. Formidable as this symptom may appear, we have not found it dangerous. At this moment a man is recovering, whose tongue was not only as just described, but of the most livid blackness.

We have mentioned, among the symptoms of debility, a partial palsy in the retina; for to this is owing the appearance of small black bodies which the patient wishes to pluck off. An equally, perhaps a more, dangerous symptom is double vision. Deafness has been esteemed a favourable sign: we can at least observe that we have not found it unfavourable. Depraved taste is very common, and offers no particular prognostic.

We have said that a putrid state of the fluids is a sign of considerable debility. This is ascertained by effusions of blood from the different organs, without any peculiar commotion in the system; dark spots on the skin, of different sizes; sometimes dark or livid stripes, like weals, from the lash of a whip; effusions of yellow serum; but, above all, by a cadaverous offensiveness of the breath, sweat, urine, and the other excretions.

If, however, in a fever, the pulse, during the first ten days, does not exceed 108; if the expression of the countenance is unchanged; if the subsultus of the tendons do not come on; if the mind is steady and unruffled; the sleep, though short and interrupted, refreshing, and the patient is sensible of having slept; if the tongue is clean at the edges; the epigastric region neither tense nor painful; if the patient lies on either side, and awakes without hurry or confusion; we may prognosticate a safe termination. But every prognosis in fevers should be made with much hesitation and reserve. Many accidents occur in the progress, which the greatest acuteness cannot foresee, nor the most guarded caution prevent.

We have said "during the first ten days," because we are convinced that fevers proceed in a regular course, and that the changes happen on the days usually styled critical, as already explained (see *CRISES*). In the more usual cases of fevers that we observe, if the disease is properly managed in its earlier period, and the circumstances are on the whole favourable, there are few instances in which a salutary change does not take place on the fourteenth day. Where this is not observable, a gradual amendment takes place, which is clearly conspicuous on the seventeenth, and the fever has disappeared before the twentieth. In common fevers we have not found the disease grow worse after the tenth day; and if no apthæ or any unexpected accident occur from that period, we have usually led the friends to expect a favourable termination.

Prognostics are also occasionally derived from the pulse, the urine, and the tongue. We have already mentioned the judgment which we may form from the number of pulsations; but numerous other changes occasionally occur, scarcely to be conveyed by description, and which have been pointed out by the ancients as indicating particular critical discharges. Galen, it is said, on feeling the pulse, called immediately for a basin,

which was scarcely brought when the blood gushed from the nose. Critical discharges are, in this climate, less common; nor can we easily distinguish the variety of pulses which authors have described. In general, the favourable signs are, a pulse more soft, somewhat fuller, and in a slight degree more slow: they seldom, at the first change, sink considerably in number. The unfavourable signs are, a more thready pulse, as if the artery was smaller, pulsations quick, weak, and irregular. The redoubled pulse, which strikes the finger twice during the space of one diastole, we have seen in two instances, without its being followed by any particular change.

The state of the *urine* has also afforded numerous prognostics, and the discrimination of its clouds, its sediment, &c. have been peculiarly minute. The greater number of these appearances may be disregarded. In general, a scum on the top, in the early period of fevers, seems to show considerable debility; and we have usually found such fevers slow and tedious. A cloud, suspended at first near the top, and afterwards falling lower till it in succession reaches the bottom, of the glass, are favourable signs; and a suspended cloud, previous to the fourteenth day, shows that the disease will terminate at that period. If it appear after the fourteenth day, the disease terminates at the twenty-first, gradually lessening on the intervening days. The red sediment is almost peculiar to intermittents and gouty habits; but a salutary sediment is usually of a reddish cast, though it is sometimes white, and of the consistence of mucus.

The appearances on the tongue are more obvious. The fur on the tongue, in fevers, is a change which takes place in its papillæ: it is by no means, as has been represented, inspissated mucus; nor will any rubbing take it away. The fur first appears in the back part of the tongue, and extends from thence in a long stripe through the middle. For many days the top and the edges are clean, the fur white, or of a light brown. After some time the colour becomes dark, and often, at last, the whole tongue dry, hard, insensible, and incapable of motion. The first favourable change is a little softness at its edge, or tip, which gradually extends in a direction opposite to that in which the tongue was covered. Every softness is not, however, equally favourable. About the eighth or tenth day the tongue will sometimes grow soft, and apparently clean; but instead of the healthy speckled appearance, it is uniformly red and shining. In these circumstances it again grows dry, but not furred; and this usually happens when the fever is protracted to the twentieth day. A blackness of the tongue is considered as a fatal symptom; but we have seen in such circumstances as many recoveries as deaths.

The *cure of fever* is a subject of peculiar difficulty, and to examine it in all its details would extend this article very far beyond its due proportion. We shall prefer giving a comprehensive outline; and will admit that we have unreasonably misspent the reader's time, if the whole that has been said on this subject does not shorten and elucidate our present inquiry.

The first question which arises is, whether fever is a disease or a remedy? Had not this been started by authors of credit, it would have appeared too ridiculous to have merited a moment's notice. In fact there is but one case in which increased heat has been suspected

of a salutary tendency; viz. in cases of obstruction. The old opinion was, that obstructions in the liver, or other viscera, arising from agues improperly or prematurely stopped, might be removed by a return of the fever. They might be, perhaps, removed by a more judicious treatment of the disease; but the fever itself would rather tend to increase them. Another case in which increased action of the sanguiferous system seems of service is palsy; and it was the former practice to increase the heat, which after a few hours from the attack supervenes, by stimulants of every kind. Modern refinement has anxiously endeavoured to remove plethora, or congestion, previous to the stimulating plan; but their success has not, we think, kept pace with the plausibility of the idea; and the former practice, except in the young and the strong, who are very rarely victims of such a complaint, seems more advantageous.

As we have stated that fevers consist in debility, it may be supposed that our cure is simple; and that the modern practice of "throwing in" the bark will be at once enforced. Tonics, however, act chiefly on the moving fibres, and remotely, as well as weakly, on the nervous system; but the debility of fevers is that of the sensorial power, which, from the views stated (see *CEREBRUM*), we cannot separate from the medullary system of the brain. If, however, our tonics were effectual in restoring activity to this part of the body, they would be inadmissible in these diseases.

The first effect of the debility is, we have said, to confine the fluids to the larger vessels, particularly, for the reasons assigned, to the liver and brain. No axiom in medicine is, however, more certain, than that to constrict over distended vessels is to add to their debility. For such reasons, in all cases of plethora, particularly where it is connected with an inflammatory disposition; in all cases of obstruction, the bark is injurious. (See *CORTEX PERUVIANUS*.) It is necessary therefore; in all fevers, to overlook for a time their cause, and attend to its effects. Even the remote causes, when they have once produced the disease, seem neither to add to nor modify it, and may be equally neglected.

Two methods of extinguishing fever at once have been employed; the one consists in evacuations, and the other in the application of cold. We are confident if, on the first shiver, an emetic be given, followed by a warm sudorific, and within three or four hours an active laxative, so that the operation of the whole shall have been completely effected within the limits of the first period, the fever will, in almost every instance, be stopped or disarmed of its severity, and be no longer a disease. If the second period has commenced, the chance of success is less; but we have succeeded. Beyond that time we can only regulate the progress of the disease, and conduct it safely to its termination. Cold, it has been said, by Dr. Kirkland and our predecessors, will have the same effect of at once checking fevers. It is not true. Cold is a remedy of singular importance; it will greatly mitigate the symptoms; it will render the solution of a paroxysm more complete; and in remittents or eruptive fever, so far lessen the complaint as to be no longer dangerous; but it will do no more.

Our chief indications in fever are to lessen the heat; to restore, as far as we can, the balance of the circulation; and to support the strength.

1. *To lessen the heat.*—We have considered the heat as the first change in the series of causes and effects, arising from the "quiescence of the capillaries:" it must of course be the first object of our attention; and the numerous advantages arising from cool air and cool drinks evidently show that the increased action cannot be a salutary exertion. This subject includes the whole that we have to remark regarding the general management of fever, with respect to diet, air, &c.

The chamber should be high and airy: the bed, if possible, neither between the door and the window, or the latter and the fire, so that the patient is never exposed to a current of air. No pictures, or other objects, should be on the walls, to fix their attention, or suggest incoherent images. It should be quiet and unconnected, if possible, with the house. The bed should have curtains, but they should not be drawn, except where the patient is exposed to the light. The window should be shaded rather than darkened. The bed clothes may be regulated according to the weather, and former habits; but should be cooler than usual, and still further diminished if the heat is considerable. Except in very severe weather, the sash should be a little open; nor need the door be solicitously closed. When fires are otherwise wanted, some may be kept up for the sake of the nurses rather than the patient. In general, when a person enters the room from the open air, he should neither feel it warm nor more close. In a long fever, the room may be occasionally mopped; but, on the whole, we disapprove of sprinkling it with vinegar. The professed object is to prevent infection; but we fear it is sometimes employed to conceal the bad smells of what ought to be removed. These should be counteracted by the most unremitting cleanliness in the bed and body linen; the former of which should be changed every two or three days, and the latter every day; in case of involuntary discharges, as often as may be necessary. It is not unusual for patients to throw aside the clothes, or to be anxious to come out of bed; and they are greatly irritated at being prevented from doing either. We have never found such indulgences injurious; and when they are no longer opposed, they seldom persist in their wish. If their clothes are immediately brought they will again lie down.

It has not been uncommon, in the early periods of fever, to carry persons into the air. If this can be done without any, or with very slight, bodily exertion on their side, it is generally useful; but to walk any distance, or to travel many miles, has been frequently injurious; and even fevers, apparently slight in their commencement, have ended fatally when considerable fatigue has been experienced in the early stages. The surgeons of the army have given an opposite opinion, which we can only reconcile by reflecting, that we have very different constitutions as the objects of our practice. Generally, on the first attack of fever, patients should preserve the greatest tranquillity of mind and body. They should either keep in bed or on the sofa, with free air and in a moderate temperature. Few visitors should be admitted and no strangers; conversation should be general and easy; and those who come should be cautioned to stay only a short time. If, by the means lately stated, the fever should be crushed in the bud, the same precautions will be useful during, at least, the first septenary period.

The diet should be equally calculated to avoid exciting heat. The appetite is lost, and solids cannot be swallowed. The liquids taken should be cool, and not highly nutritious: barley water, tea, toast and water, bread jelly, or weak broths, are sufficient for the early periods of fever; and this very light diet should be kept up during the first six days. If the debility is considerable, a diet somewhat more nourishing may be allowed earlier; but the loss of strength should be indeed very great to admit the use of wine during this period. The patient should be supplied frequently with these liquors; and if he complain of coldness they may be given warm. After about the sixth day the diet should be more nourishing, and good broths, jellies, and occasionally a little wine, may be allowed; but the latter should be in moderate quantities, lest we exhaust the powers of the best cordial that we can at a future period employ. The ancients gave the coldest water freely in the earlier stages of fever; and we have often indulged our patients in this practice, always without injury, and often with the most striking advantages.

Some late trials would suggest the question, whether, in the earlier stages, cold may not be employed more actively than in these plans. We allude to Dr. Currie's recommendation of cold affusions, and particularly their effects in scarlatina. In his practice they are only employed to counteract violent heat; and the heat is greatest in those inflammatory fevers which are generally accompanied with local inflammation, or where we expect hourly local inflammation to take place. We own that we have hesitated in using this remedy with that spirit and decision from which alone we can expect salutary consequences. In a less degree, sponging the body with cold water has been found useful in mitigating the heat. It is also highly refreshing and agreeable to the patient.

2. *To restore the balance of the circulation.*—This is the most important indication in the cure of fevers; and to this object our chief attention must be directed. The natural, and sometimes the bilious, vomiting will point out the necessity of giving *emetics*. These are our chief dependance in the early stage of fever; and from our view of their effects, the force of their benefits will be sufficiently obvious. (See *EMETICA*). The chief advantages are, however, relieving congestions in the liver, and determining to the skin. The former is obtained by active vomiting; but it has been supposed that the latter may be secured by means less violent, and more permanent in their effects. Active vomiting is seldom employed more than once; but if the first emetic should not act completely, it must be repeated. The antimonials are preferred in fevers, but without sufficient reason, as we seem to gain all the benefit of full vomiting from the ipecacuanha. Dr. Fordyce attributes some of this benefit to the medicine; for the vomiting, he remarks, procured by squills, is not equally successful. On this subject we cannot speak from experience. In general, after the operation of vomiting, we should endeavour to secure the determination to the skin by some mild diaphoretic with which opium is combined.

To support the action of the extreme vessels by nauseating doses of emetics, is a practice introduced from the theory of Dr. Cullen. There are no doubts of the utility of this practice; but we are confident that it has

been carried too far in the Cullenian school. To explain the action of the nauseating doses of antimonials—for to these we would confine, with Dr. Fordyce, the advantages we derive from such medicines in fevers—is not easy, when we have found that their relaxation is the effect of a sedative power, and that the spasm, if we may still use the expression, arises from debility. It must be, however, recollected, that when we spoke of the quiescence of the capillaries, we did not object to the spasmodic state of these vessels if considered as the effect of irregular action. From all the phenomena, from the effect of every remedy, it is not mere inactivity. Whatever becomes of theory, medicines exciting nausea really promote perspiration, often of a most salutary kind; and whatever fills the extreme vessels, and, more particularly, whatever promotes any discharge from them, relieves internal congestions. Experience, however, limits their use, and perhaps they should not be continued beyond the third or fourth day. They undoubtedly produce, after some time, debilitating effects; and in the long protracted fevers have been injurious when too far pursued.

When we spoke of *CATHARTICS*, we explained at some length their advantages in relieving congestions of the viscera and the head. In this way they are well adapted for the relief of fever; and that article, as well as its application, was formed long before the appearance of Dr. Hamilton's work. In fact, for more than twenty years we have given cathartics freely in fevers, with the most salutary effects; and we consider them as medicines of the greatest importance. In the larger number of epidemics, though active in their operation, they do not weaken the patient, for they take away the cause of, at least apparent, weakness; and we have often found patients in fevers taking bark and wine in profusion, to support them under this apparent debility, who, after the operation of an active laxative, required neither. Let not the young practitioner be terrified by the number of evacuations, but attend to the effects, and to his patient's feelings. If he is relieved after each stool, if the pulse becomes softer, the hand more moist, and the head less loaded, he need not be apprehensive, however violent the discharge. On the contrary, if the pulse becomes smaller and more frequent, if the face sinks, and faintness comes on, however little the discharge, it has been too much. We trust, that when we have laid down this obvious criterion, we shall not be accused of pushing a theory too far: we have at least given an antidote, should we have administered a poison.

It is necessary, however, in the employment of this remedy, to attend to the discharges. The nurses will often report frequent, numerous evacuations; and if examined, these may be found mucous and inefficient, or a watery fluid, scarcely coloured. It is necessary that the stools should be truly feculent; and these should be continued while any tension can be felt in the epigastrium and abdomen, or while the discharges continue to be dark and offensive. Such they always are in the early stages of fever.

The use of cathartics in fever was the practice of the most ancient physicians; and they were apparently disused, in consequence of the idea that they prevented the discharge by sweating. Hippocrates and his followers depended more on clysters and suppositories. In

fact, they had only the more violent cathartics, as the milder ones were introduced by the Arabians; and these very active medicines were injurious by the debility they occasioned. Hippocrates, Galen, Aretæus, and their followers, employed purgatives early; and their chief reason was to prevent the diarrhœa, which would, they supposed, supervene on the fourteenth day, when the patient would be too weak to bear the discharge. The methodic sect only discouraged their use; but they apparently supplied the defect by enjoining strict abstinence for the first three days. In more modern times, Borelli, Baglivi, Donckers, Sydenham, &c. &c. employed them, though we suspect not to the extent which we have found salutary. Fevers, however, in different situations may greatly differ; and we would anxiously deprecate the application of the practical rules suggested in one situation to diseases of a different country, without exact attention and a due discrimination of the circumstances. We suspect, however, that this class of remedies will always be found very important auxiliaries in fevers of almost every climate.

The choice of the purgative is of some importance. The more violent drastics debilitate too powerfully; and, on the other hand, the salts, the castor oil, the tamarinds, and manna, appear not to excite the action of the moving fibres of the intestines sufficiently to evacuate the more hardened contents. The purgatives which we have found most effectual are, the senna, with a small proportion of the scammony; or the jalap, generally united with the cream of tartar, sometimes with calomel. Nearly similar in effects is a mixture of rhubarb, with some neutral, in equal quantities.

It has been too common to depend on clysters; and in those fevers where Dr. Hamilton has with so much success procured numerous motions, we have known practitioners of eminence content with daily clysters, if stools did not otherwise occur. In general, clysters evacuate only the contents of the rectum, unless they are of a highly stimulating nature, where their peculiar irritation is communicated to the superior portion of the canal; and clysters of warm water, and the usual preparations for this purpose, are inert and inefficient remedies. They certainly give some relief; but this is temporary only, and far inferior to that procured by the operation of an active cathartic. In cases of great debility, where we are apprehensive of the effects of a too copious evacuation, clysters only can be employed.

DIAPHORETICS are remedies of equal utility; but unfortunately they have been improperly chosen, and the process has been most erroneously conducted. The only salutary discharge from the skin, as we have already explained, is the halitus in the form of gas, or rather of a thin, probably of a vesicular, vapour. When in a fluid state, it increases the oppression it was intended to relieve. This salutary diaphoresis is inconsistent with increased heat; and to promote it in fevers, the heat must be diminished as near as possible to the standard of health. *Cooling medicines* are consequently the most effectual diaphoretics; and cold water one of the most powerful. *Nitre* and the other *neutrals* act chiefly in this way; and the citras potassæ, the common saline draught, which it is usual to ridicule, certainly refreshes the feverish patient by the coolness which it imparts to the stomach. *Vegetable acids* produce a similar effect; and of these vinegar is preferred,

as more powerful in its action on the skin. The native acids (the acid fruits) are, from their coolness, salutary and refreshing, and moderate the heat to the proper degree for this discharge. The mineral acids act, we think, differently; and, if the febrifuge spirit of Clutton is useful, it probably is so in an advanced period of fevers of the lowest kind: the spirit of salt, recommended so warmly by Reicht, is certainly not referrible to this head.

Nauseating doses of antimonials operate powerfully and safely as diaphoretics. Dr. Fordyce supposes this effect to be owing to the medicine, and not to the action on the stomach. For this reason, perhaps, antimonials are continued in the early stages of fever, with little anxiety respecting the nausea they produce; and if not persisted in too far, they are undoubtedly useful. They sometimes appear inconvenient from their purgative effects; for we think we have found that the purging produced by antimonials is not equally beneficial with the discharge produced by other medicines. The union of the nauseating doses with calomel, lately fashionable, has not in our hands succeeded so fully as, from the warmth with which they were recommended, we had reason to expect. The more active and heating sudorifics are inadmissible in the greater number of fevers; and wine, which sometimes acts in this way, will be more fully considered under another head. We chiefly want these last medicines when it is our object to prevent the accession of the paroxysms of an intermittent, or to relieve the pains of rheumatism. The semicupium pediluvium or warm fomentations to the lower extremities are often safe, and highly useful, diaphoretics. See BATHING.

BLISTERS very powerfully restore the balance of the circulation, and diminish morbid congestions in the head and the liver; but, except the latter organ is inflamed, they are applied only to the head and neck. We have under this title fully explained their operation, so far as it is understood. In all cases of fever there is, as has been observed, fulness of the vessels; and we find the vessels of the eyes red, the face flushed, and the eye ball itself apparently enlarged; but this congestion produces also irritation, and often a less degree of phrenitis. The usual wanderings of the mind are more rapid, the voice quick, the temper irritable, unreasonable, and occasionally violent. In each state blisters are indicated, and often produce the happiest effects: sleep frequently coming on, as soon as the plaster begins to stimulate. The milder symptoms of congestion, first described, yield frequently to purgatives; and when these have been freely used, blisters are often necessary.

SEDATIVES.—Congestions in the brain, as we have just remarked, produce considerable irritation; and the state of irritability thus occasioned requires often the most active sedatives and antispasmodics. In other views, remedies of this kind are highly useful. They check often the too impetuous current of the blood to the head; they produce a calmness and serenity, which greatly assist the action of medicines that determine to the surface; and they remove a very troublesome symptom, flatulence in the stomach and intestines. The chief of these are camphor and opium. *Camphor* is a medicine of considerable utility in fevers, as already shown. The calmness which it often seems to inspire;

the serenity, and even the temporary ease, which are among its first effects, render it peculiarly valuable. As it sometimes appears to increase the heat of the body in the earlier stages, a little nitre may be added, with an antimonial; in the latter, the sal c. c. the aromatics, or the bark. There is, however, apparently no period of the disease to which it is not adapted, and no species of fever in which it is not beneficial.

Opium is a medicine of more doubtful efficacy: it often irritates instead of calming, and produces agitation instead of a serene freedom of spirits. With those in whom it produces its mild sedative effects, it is a very valuable remedy, and, united with camphor, it seldom disagrees. In the later periods of fever, when subsultus and convulsions come on, opium and camphor are the best remedies. Some practitioners have been violently averse to the use of this medicine. They observe that it debilitates; but the true reason of their dislike, we suspect, is the probability of its suppressing critical discharges. They have contended that the most restless night is less injurious than the stupor produced by opiates; and that even the chance of their hurrying the spirits, is more to be dreaded than any advantage to be derived from them can compensate. While we own our predilection for this remedy, the accusations are not wholly groundless. Opiates check all the evacuations, except those by the skin; and we certainly neither gain so much by the tranquillity they procure, nor lose so much by a sleepless restlessness, as may be at first supposed. Yet we think if the patient's strength is preserved by their use; the hours pass away more comfortably; time insensibly wastes; and if we can annihilate one fourth of the patient's suffering by procuring six hours in the twenty-four, if it be no more, of torpor and insensibility, we amply compensate for the risk. The necessary evacuations we must be careful to restore.

Other sedatives have been employed to procure sleep; and Hoffman is profuse in his commendations of his *anodyne mineral spirit*, which we now know to be ether only, with a somewhat larger proportion of the *oil of wine*. We are surprised that this last medicine has not been tried alone, or in union with opium. The anodyne spirit generally fails in other hands; and though it is still given in fevers, no one seems to have found it strikingly advantageous. Among the soporifics we must not forget the *pillow of hops*; nor breathing *hydrocarbonate gas*. Some hectic patients who have been confined to a stable, or whose room has been covered, for a similar purpose, with dung, have informed us, that they think they have slept more quietly in such situations. These effusions of quackery have not been, we believe, often employed by any scientific physician; and the interested reports of unprincipled pretenders we need not enlarge on.

The chief of the other antispasmodics are ether, musk, castor, and asafœtida. *Ether* is very active in this view, and at the later periods, when subsultus comes on, and convulsions threaten, is often of considerable service. *Musk*, if in perfection, is an active antispasmodic, but it is seldom genuine; and, as a medicine peculiarly dear, is reserved for the last desperate stages: it here sometimes obtains the credit due to the operations of nature. *Castor* is less powerful; but seems occasionally to correct the injurious effects of opium; and *asafœtida* still less so. The effects of the latter are chiefly confined to the stomach; though it

sometimes appears useful as a general sedative, and occasionally as an expectorant.

It may appear singular, that among the means of lessening heat, or removing topical congestion, we have omitted *bleeding* in all its forms. The consideration was postponed to introduce it in this place, where the whole subject may be more advantageously considered in one view.

Bleeding has been a general remedy for fevers of every kind; and when the increased action is so violent as to threaten the rupture of a vessel, this evacuation is essentially necessary: it is equally so, when with, or soon after the attack of a fever, with inflammatory symptoms, local inflammation appears. Here then we would stop, did not the conduct of some practitioners in every fever, and of some respectable ones, in fevers highly asthenic, suggest to us that our limits are too narrowly restricted. Sydenham recommended bleeding in the early stages of every fever; and we are told by almost every practical author first to take off some blood; occasionally limited to patients in the prime of life, to robust constitutions, or to fevers from cold. Yet we find Dr. Dover bleeding in a highly putrid fever, not only in the commencement, but in the progress: the older surgeons have employed this remedy with little apprehension in a highly asthenic fever, the puerperal; Dr. Rush bleeds repeatedly in the yellow fever; Dr. Moseley and Dr. Jackson in similar fevers, in the West Indies, employed the same remedy. Must we condemn the practice of physicians so respectable, or must we resign all the pathological views we have attempted to inculcate? We will do neither; but may, by the way, inculcate an useful lesson: that empiricism—for such we will venture to style it—with a happy boldness will sometimes succeed, by means which the timid dogmatist will scarcely dare to follow.

Modern practitioners have taken blood to moderate the increased action, and to prevent accidents from its violence when the vessels are weak. In this way, by ineffectually employing an active remedy, they have injured by debilitating, while they have only imperfectly moderated the stimulus which they attempted to oppose. The physicians mentioned, if they had any views, employed it with different ones. If the practice of each author be examined, it will be found that they bled when the system was over loaded with the accumulated fluids from the surface; and they bled boldly, because it was necessary to relieve each part: and the quantity drawn from the arm can affect each according only to the proportion of the whole mass which it receives. We have stated, in many parts of this work, with a view to this subject, and particularly in the article of *BLISTERS*, q. v. the effects of only a slight evacuation in relieving distended vessels; effects not only derived from the diminished quantity, but from the spring this relief imparts to the muscular fibres. Whoever reads Dr. Dover's animated, but somewhat quaint, description of the case, in which he succeeded so completely, will at once see that bleeding could have relieved only in the way we have explained; and Dr. Rush's descriptions strongly elucidate the same ideas. Mr. Coleman, in his work on suspended animation, has recorded a fact which illustrates our explanation; as he found, that taking blood from the jugulars restored the action of the right side of the heart, which was suspended from distention.

If general bleeding then be useful, it must be in cases where the internal congestion is considerable, and where, from distention, the irritability of the muscular fibres of the internal vessels is for a time suspended. It will not be difficult for the experienced practitioners to distinguish this situation; and we would recommend extreme caution in this respect to the less experienced, who are, in general, too fond of the lancet.

Whatever may be the opinion of general bleeding, topical evacuations of blood have been employed to remove internal congestions. Blisters and purgatives best relieve those which occur in the abdominal viscera; but to the head, besides blisters, leeches are applied: and cupping glasses, with previous scarifications, to the neck. These are remedies which many are fond of: but, except in sudden attacks of phrenitic delirium, which sometimes come on in the progress of fever, we have found little room for evacuations of blood.

To sum up the whole of this intricate subject, the general practice of bleeding at the commencement of every fever appears highly improper. If not certainly from cold, if the patient is not in the prime of life, and if no topical inflammation apparently impends, it should certainly be avoided. In some of the worst fevers, pains in the limbs, we have said, occasionally appear on the attack, and sometimes in the progress. These should be carefully distinguished from true inflammatory ones. The reigning epidemic, the symptoms of general debility, the period of life, and the apparent cause, will assist the distinction. The features afford an excellent criterion. If these are sunk, and the character of the countenance lost in a greater degree than can be expected from the duration of the disease, general bleeding should be avoided. Even topical bleeding we would not particularly recommend, unless the congestion appear inflammatory. Blisters will supply its place more safely.

3. *To support the strength.*—This indication, apparently the most obvious and necessary, is not easily followed. Bark is a tonic; and bark has been given in profusion, with little discrimination, and with most decided injury. If, by the prudent and judicious use of the medicines already described, we can lessen the congestions in the liver and the head; if we can preserve the strength by the due regulation of temperature, and support it, after the first days, by more nourishing broths and jellies; we shall find little opportunity for administering tonics. Let us repeat, that the largest doses of bark and wine will not so effectually give strength and spirits as two or three loose motions; and no cordial will be so refreshing as free cool air. If at the conclusion bark must be given, it should be in the inefficient forms of the decoction and tincture.

We mean not, however, in every instance to discourage the use of tonics; but merely to allege that they are not alone adapted for the cure of fever, and often injurious before the infarction of the viscera is completely removed. In general, we think the simple bitters more useful than those medicines which, like the bark, unite an astringent principle. The gentian, the quassia, the camomile flowers, and even the cascarilla, if debility appears early, may be early employed; and with a neutral salt, so as to prove purgative, or sometimes with the kali only, they have appeared to be febrifuges. Though

they are chiefly adapted to the slow fevers, apparently of the hectic kind, we have thought that, in many cases, they act with sufficient energy as tonics, even in typhus, except in the desperate cases to be soon mentioned. The metallic tonics have not been fairly tried, and the most powerful, the arsenic, seems to require for its success a complete apyrexia.

Cordials are, however, often necessary; and we repeat only the opinion of the ablest practitioners, that the most efficacious cordial is wine. Unless called for by early debility, we seldom wish to give it till the eighth day, and very moderately till the tenth. Even between this and the fourteenth, unless in emergencies, we rarely order a pint in twenty-four hours. If the fever proceeds, it may be increased. Other cordials are the aromatics and ether; the former, in the usual preparation, the *confectio cardiaca*; the latter, except in cases of convulsions, in an occasional cordial mixture.

The strength is also for a time supported by the more simple stimulants. The *contrayerva* and the *serpentaria*, with ammonia, were the preparations formerly used, with a view of concocting the matter; and we once thought that we could support the strength for a day or two by their means, when a crisis was expected: but we have long learnt to "pull in resolution, and doubt the equivocation that palter with us in a double shape." These stimulants only contribute to destroy the excitability, and we fear to hasten the last fatal termination. They may be employed in cases of temporary debility; but should be carried no further than to bring back the previous state. The great errors in the management of fevers have been the ideas that tonics, which restore muscular energy, will equally restore the sensorial power; and that which confounds temporary heat and more rapid circulation with increased strength. Each is a fatal misapprehension. It has been an error equally dangerous, when debility comes on, to rouse the patient by light and noise. Life is a forced state, says the ignorant and mistaken Brown, and the lamp must be excited by additional powers: it will be excited only to exhaust more rapidly the pabulum which supplies its existence.

Among the more unexceptionable tonics we may mention the mineral acids. These are of importance when considerable debility comes on; and a German physician, M. Recht, has endeavoured to raise their value by representing the muriatic acid as a general remedy in fevers. The secret was magnified by interest or collusion till it became a national object, and it was purchased by the king of Prussia. The muriatic and vitriolic acids had been long used in this kingdom in low, nervous, or putrid fevers, and considered as useful, but by no means infallible, medicines.

There are cases, however, where the strength is greatly lessened, and where a putrid dissolution of the blood becomes a most dangerous symptom. The mineral acids are, in such cases, remedies of considerable importance; and the bark becomes an indispensable medicine in the largest doses. These circumstances, however, seldom occur in general fevers; and, indeed, within a few years, we have scarcely seen an instance of this kind, except when a topical gangrene, as in the ulcerated throat, has concurred. We cannot then be

too active in the employment of cordials and tonics, among which the mineral acid must be ranked; for if we do not gain some ground within a few hours after the appearance of these symptoms, the patient is lost. The other tonics formerly mentioned are not of sufficient power for such emergencies.

We cannot leave this subject without noticing the necessity and the means of obviating some of the more troublesome symptoms. The chief of these, the want of sleep, has already been the subject of our notice. The state of the stomach is also the source of considerable inconvenience. Acid eructations and heart-burn are relieved by absorbents, as magnesia, chalk, or kali; but we must recollect that we have already distinguished a species of heart-burn arising from oily substances, not mixed with the contents of the stomach, relieved only by mucilages. Nidorous eructations show the stomach to be in a putrid state, and this is corrected generally by vegetable, but more effectually by mineral, acids. Flatulent distention will seldom be troublesome, if the discharge of the bowels be kept up. Should it be so, asafetida and galbanum, or their tinctures, with peppermint water, will relieve. Hiccough, at the latter end of fever, is sometimes highly distressing; and for this we have no certain remedy. Oil of cinnamon, camphor, musk, and opium, are given by turns; and one or other of these occasionally succeeds, though often all fail. Applications of opium, or of a blistering plaster to the stomach, will, like the others, in turn succeed and fail. But though a distressing symptom, hiccough is not, as has been represented, a fatal one. Did it not fatigue and weaken the patient, we should scarcely think it dangerous.

Palpitation of the heart is sometimes troublesome, but not always dangerous in fevers. It sometimes proceeds from the state of the stomach and bowels, and may then be relieved: but it arises also, in many cases, from a diminution, or an irregular distribution, of the nervous power; and shows that the degree of debility is considerable. The low, muttering, wandering delirium, is a symptom of the same kind; but this is so strictly connected with the state and progress of fever, that it scarcely merits our notice in this place.

Strangury, though often the effects of blisters, sometimes occurs in fevers without their application, and arises from a spasmodic irritation of the neck of the bladder. In this case opium, particularly in clysters, is the most effectual remedy.

Hæmorrhages sometimes occur in fevers, which occasion no little difficulty. If the pulse be full and hard; if much headach has preceded; if faintness does not follow the evacuation; but, on the contrary, the pulse becomes softer and slower; the bleeding may go on. If it happen at the conclusion of fever, and be attended with faintness, it is highly dangerous. Cold, bark, and the mineral acids, have been accounted the best remedies; but even in this low state we have found nitre successful in repeated doses. It is indeed one form of employing cold. See HÆMORRHAGIÆ.

Longings for particular foods are sometimes troublesome. These must be distinguished from the caprice of the moment; and if the patient continue to desire, with much anxiety, any particular food, we have found

that he may be more safely indulged than contradicted, even should the desired food appear highly injurious. We have known wine anxiously longed for; and a very large quantity drunk in a short time, not only with impunity, but advantage.

Among the sequelæ of fever are cough, night sweats, an irritable and irregular state of mind, a capricious and often an inordinate appetite. These are, in general, marks of debility only, and disappear with returning strength. Bark and tonics are usually employed for a time with little effect. The constitutional powers are at last exerted, and the patient gains in hours the strength which, with the most powerful tonics, it did not attain in days. The powers of digestion, however, do not return in the same proportion as the appetite, and relapses are not uncommon from unlimited indulgence.

See Sydenham; Grant's Observation on the Nature and Cure of Fevers; Kirkland's Essays towards an Improvement in the Cure of those Diseases which are the Causes of Fevers; Fordyce on Simple Fever; Cullen's First Lines, vol. i.

The great varieties of fevers we shall in a future part of this work endeavour to bring within more strict limits. It would be to anticipate what can only be then detailed with advantage to add any thing at present on the subject, and we shall of course preserve the various references in the former edition with little change.

FE'BRIS ACU'TA SANGUI'NEA. See INFLAMMATORIA FEBRIS.

FE'BRIS A'LBA. See CHLOROSIS.

FE'BRIS AMATO'RIA. See CHLOROSIS.

FE'BRIS ANGINO'SA. See SCARLATINA ANGINOSA.

FE'BRIS CA'ROERUM. The JAIL FEVER; a severe kind of typhus, called *typhus carcerum*. See AMPHEMERINA HUNGARICA, and TYPHUS.

FE'BRIS CASTRE'NSIS. The CAMP FEVER; a remittent tertian, called *typhus castrensis*, from its resemblance to typhus. See TYPHUS.

FE'BRIS CONTI'NUA PU'TRIDA. See PUTRIDA FEBRIS.

FE'BRIS NON PU'TRIS. See INFLAMMATORIA FEBRIS.

FE'BRIS DEPURATO'RIA SYDENHA'MI. A variety of synochus.

FE'BRIS EPIDE'MICA CONTAGIO'SA. Epidemic fever of the West Indies and Philadelphia; malignant pestilential fever of Chisholm; bilious remittent yellow fever of Rush; synochus icteroides, or yellow fever of Currie. See BILIOSA FEBRIS.

FE'BRIS ERRA'TICA. Erratic fevers, irregular tertians or the quartans.

FE'BRIS FLA'VA. See BILIOSA FEBRIS.

FE'BRIS HUNGA'RICA. See AMPHEMERINA HUNGARICA.

FE'BRIS INTERMITTENS. See INTERMITTENS.

FE'BRIS LENTICULA'RIS, also PETECHIALIS. A typhus, or synochus, attended with spots in the skin, about the size of lentils, called from these appearances *spotted fevers*. See PETECHIALIS FEBRIS.

FE'BIUS HYDROCEPHA'LICA. See HYDROCEPHALUS.

FE'BRIS MALI'GNA BARBADE'NSIS. See BILIOSA FEBRIS.

FE'BRIS MALI'GNA HE'CTICA: a mild kind of typhus.

FE'BRIS NAU'TICA PESTILENTIA'LIS. See MILIARIS NAUTICA.

FE'BRIS PUERPERALIS. See PUERPERALIS FE'BRIS.

FE'BRIS REMITTENS. See REMITTENS.

FE'BRIS URTICA'TA. See URTICARIA.

FE'CU'LA. See FÆX.

FEL, (quasi *foliis*, a bag). See BILIS.

FEL NATU'RÆ. See ALOE.

FELLI'FLUA PASSIO, (from *fel*, bile, and *fluo*, to flow, and *passio*, affection). See CHOLERA MORBUS.

FE'MEN, (quasi *ferimen*, from *fero*, to bear). See FEMUR.

FEMINUS, (from *fæmina*, a woman). In botany it means producing female flowers only on the same root.

FEMORA'LIS ARTE'RIA, (from *femur*, the thigh).

The FEMORAL ARTERY is the external iliac after it has passed from under Poupart's ligament, and is continued along the thigh into the popliteal. Besides ossification and wounds, this artery may be the seat of an aneurism; a disease distinguished in its early stage by its being circumscribed and small, though the pulsation is sufficiently remarkable; but as the tumour enlarges, the pulsations are more obscure, and at last no longer perceived. When the aneurism is arrived at this stage, the lower part of the leg becomes œdematous; the limb is gradually more useless; and, if relief is not afforded, a mortification will follow. The operation for the aneurism will rarely succeed in this case, for in general the artery is also diseased above the dilatation; and the want of collateral branches to carry on a due circulation is another impediment to the attempt. Amputation, in this instance, as well as when this vessel is wounded near the belly, or near the ham, is the only relief. In case of an aneurism, if, on performing the operation and tying the artery, pain follows, with fever and tension, the issue will be fatal if amputation is not performed. If the aneurismal tumour is about the middle of the thigh, and but small, it may be laid bare, and the artery tied above and below; but if the tumour is large, the artery is diseased above, and the ligature will fail. If the tumour is near the groin, amputation itself will scarcely save the patient's life; if low, near the ham, or in it, amputation is the only means of preventing a fatal mortification. See Mr. Pott's Works, and his Necessity, &c. of Amputation in certain Cases.

FE'MORIS OS, (from the same). THIGH BONE; *anchæ os*. In the thigh there is only one bone; it is the largest and strongest of those which are cylindrical. On its outside, near the neck, is a large tuberosity, the trochanter major; rotator major, rotator natis; and a lesser one, on the inside, the trochanter minor; rotator minor. The posterior concave surface of this bone hath a ridge rising in its middle, called the *linea aspera*, divided below into two. The inferior extremity of this bone is formed into two condyles, between which a considerable cavity is found, especially at the posterior part: these are contiguous forwards, but at a distance backwards. The os femoris is articulated to the acetabulum by enarthrosis; to the tibia and the patella by gingly-

mus. Winslow observes, that all the processes from this bone are cartilaginous in new born children.

Though the thigh bone supports the whole body it is by no means, in appearance, advantageously constructed, since it bends inward towards the knee, and outwards at the top; but the former was necessary to avoid a rotatory motion of the leg, and the latter to form a sufficient space for the organs at the bottom of the abdomen.

As the great trochanter passes off at nearly a right angle to enlarge the cavity just mentioned, any shock of the trunk renders it liable to fracture, and this is often mistaken for luxation; an error with difficulty corrected, as the muscles are so thick and so numerous in this part.

FEMUR, (from *fero*, to bear; as being the support of the body). The THIGH; *femen*, (quasi *ferimen*), *coxa*, *agis*, *ancha*, *crus*, *meron*.

FENE'STRA OVA'LIS et ROTU'NDA, (from *fenestra*, a window). See AUDITUS.

FERE'NTIS. See ARBUTUS.

FERI'NA, MANIODES, (from *μανια*, and *furor*, *ειδος*, *forma*,) a violent and furious delirium.

FERI'NUS, (from *ferus*, wild). SAVAGE, or BRUTAL; in a medical sense it signifies noxious or malignant; and is applied to coughs, &c.

FERMENTA'TIO, (from *fermento*, to ferment). FERMENTATION, *ecbrasmus*, *bramos*, is an intestine motion excited, with the assistance of proper heat and fluidity, between the integrant and constituent parts of farinaceous and saccharine substances, from which result new combinations of their principles. The heat required is about seventy degrees of Fahrenheit's thermometer.

The phenomena of fermentation are, however, now better understood than by the chemists of the old school; and this may, perhaps, excuse our enlarging on a subject not strictly medical, though the term is so common in medical authors; but employed without any scientific discrimination.

The subjects of fermentation, we have said, are farinacea and sugar; but the former are scarcely rich enough in the saccharine principle to ferment without some preparation. This consists in wetting, and in exposing the grain to a degree of warmth to excite the process of vegetation; but no new saccharine principle is added: it is merely more completely developed. Sugar must be employed in every fermentation; but it requires about four times its weight of water. With the sugar, mucilage is also requisite; an ingredient which the coarse sugar usually contains. But it is singular that a vegetable acid must also be previously contained in the substance to be fermented (*Annales de Chimie*, xxxvi. 23.); and this we shall find to be supplied, in beer, by the barm or yeast, and is contained naturally in all the fruits.

When these ingredients are in due proportion, and the temperature raised to nearly 70°, an intestine motion commences; the liquor becomes thick and muddy; an additional degree of heat is excited in proportion to the rapidity of the process, which sometimes rises so high as 95°, and carbonic acid gas arises. In this process the sugar disappears, and the fluid becomes clear, as well as of a less specific gravity; and, as it is

styled, of a vinous taste, owing to the formation of alcohol. The other ingredients seem merely to have assisted the process, and to remain unchanged; for we still find the mucilage both in wine and beer, and the vegetable acid in the former; though the small portion employed as a ferment in the latter seems to have escaped with the carbonic acid gas. Thus the sugar appears to be in part decomposed, and to have separated in the form of carbonic acid gas; and the other part, with a large excess of hydrogen, forms the alcohol, combined with the colouring matter, and the vegetable acid. The superfluous extractive matter, which the vinous liquor cannot dissolve, rises to the top, or sinks to the bottom, in proportion to the quantity of air entangled with it.

In this process a portion of malic acid is formed, perhaps from the tartarous; and some oxygen is seemingly evolved. It was supposed that the latter was derived from the open air; but Fabroni has informed us that fermentation proceeds with equal rapidity and success in close and in open vessels. *Annales de Chimie*, xxxi. 302.

After this active process of fermentation is at an end, it still proceeds in a more slow, often in an imperceptible, way. If wine or beer be kept in a heat, from 70 to 90 degrees, it gradually thickens, grows hot with a gently hissing noise, and filaments are observed to move in it, though previously fine. The heat and noise lessen, the filaments subside, and the liquor is again clear; but it is no longer vinous: it is acid. The result of the acetous fermentation seems not to be connected with the alcohol. Yet if the assertions of some of the older chemists, that the strongest wines, when rendered acid, afford the strongest vinegars, be true, alcohol may probably have some effect. These vinegars have not, however, been examined; and we strongly suspect that they would appear to have been impregnated with acetous ether. The extractive matter seems to be the substance which first experiences the change; for when it is carefully separated, wine will not become sour, though found by Chaptal to become acid, when vine leaves were added. (*Annales de Chimie*, xxxvi. 245.) It is said also, with some truth, that fermented liquors do not become acid, unless they are exposed to the atmosphere, from whence the oxygen, essential to the acidity, is absorbed. There seem, however, to be some cases, in which this exposure to the atmosphere is not necessary; for wine will become sour in well corked bottles. In general, however, no cork is sufficiently tight to prevent, after some time, the escape of alcohol; and the atmospheric air finds access by the same course; in bottles which contain acid wine, some space will always be found empty, and the acidity is in proportion to this space. The flakes are owing to the extractive matter which commenced the process; but some portion of this still remains, and the malic acid is the last to experience the change.

The last stage of this important process is *putrefaction*, in which the extractive matter is still more completely separated, and organisation wholly destroyed.

This is the common and regular process; but it is sometimes varied in almost every step. In many instances, no traces of a vinous spirit are found, but the fluid hastens rapidly to the state of vinegar. At other

times putrefaction as quickly comes on; and, in some of the stronger wines and cyders, no art can apparently convert them to vinegar. We have exposed some of the strong Devonshire cyder for a whole summer under a sunny wall without producing vinegar. The appearance of vinegar, though it presupposes the existence of a vinous state, therefore by no means confirms it; for the vegetable acid may be produced in a variety of ways, by distilling gum, sugar, wood, or tartars, by the action of sulphuric acid in a concentrated state on these bodies, or by the spontaneous decomposition of some animal substances, particularly urine.

It has been supposed, that if gluten forms a large portion of the fermenting bodies, ammonia will appear in the product; but this has little foundation. The only varieties in the process are those mentioned, with the greater quantity or perfection of each of the results, which are subjects rather economical than chemical or medical.

We have remarked that a vegetable acid is necessary to excite fermentation; and that in the process of making beer from malt, a ferment of this kind is necessary. In different places, where the wine is of different qualities, the ferments are of course various. Thus on the Rhine, where the grapes are peculiarly acid, they add fresh meal; the Chinese add a decoction of barley and oats; and we sometimes assist the more insensible process, after the active period is at an end, by a little wheat or barley.

The ferment usually employed for beer is barm or yeast, which Mr. Henry has imitated by the union of carbonic acid gas, with some mucilaginous substances capable of entangling the air. Good barm is, however, a very complicated mixture, containing the carbonic, mucous, acetous, and malic acids, alcohol, extractive matter, mucilage, sugar, gluten, and water, besides some lime and potash, with traces of silica and phosphoric acid. Mr. Westrumb, however, in *Crell's Annals*, has found that the only essential part is the gluten, with a vegetable acid; and it is seemingly indifferent of what kind this acid be, if it is of vegetable origin.

In the human body, by a loose analogy, fermentation has been said to take place, and all its various phenomena have been supposed to produce corresponding effects. We have thought it probable that a similar process takes place in the stomach; but there is not the slightest evidence of any fermentation in the circulating fluids. What former physicians intended by this term is rather an assimilatory process, by which, at least, the poison introduced is increased in quantity; but there is no foundation for supposing that all the fluids are thus changed. In the small pox, for instance, some change occurs; and all the matter which passes through the skin, as well as that which is stopped in its passage, and produces the pustules, will excite the disease in a person liable to it; but the effects soon cease, and all the matter thus changed is at once carried off; for neither in small pox nor measles will the blood convey the disease. In all assimilatory processes, however, there is a strange mystery which we cannot develop; and there is no little probability that the whole depends on the state of the capillaries produced by the fever. We purposely eluded this consideration under the head of *EXANTHEMATA*, as we had not then matured the ideas that

then occurred to us. We may resume the subject when speaking of the different individual diseases, if we can reduce our suspicions to a probable shape.

FERME'NTUM, (quasi *fervimentum*, from *ferveo*, to work, as wine in a vessel). FERMENT, BARM, YEAST, LEAVEN, *corocrum*.

Pliny, in his Nat. Hist. lib. xviii. c. 7. speaks of the barm from malt liquor being used in Spain and Gaul to make bread, which was in consequence lighter than that of other nations. Many other substances excite fermentation, but this ferment is always preferred. Yest has been given in putrid fevers, and has, it is said, produced the most happy effects. The usual dose is a large table spoonful every three or four hours; but the dose and repetition should be adapted to the exigencies. We have had little experience of its virtues, but suspect them not to be considerable. See FERMENTATIO.

FERRÆME'NTA CANDE'NTIA, (from *ferramentum*). HOT IRONS. See ESCHAROTICA.

FE'RRATE, A'QUÆ, (from *ferrum*, iron). See AQUE CHALYBEATÆ.

FERRI RUBI'GO, (from the same.) See FERRUM.

FERRI TI'NCTURA MURIA'TI. See FERRUM.

FE'RRUM, (from *fero*, to wound); IRON; *chalybs*, *Mars*, *aquarius*, *biladen*, *hadid*. Its chemical character is §.

Iron is a bluish white metal, very hard, admitting of a brilliant polish, styptic to the taste, and emitting a smell when rubbed; the next in specific gravity to copper, between seven and eight times heavier than water; distinguishable from all other bodies in its metallic state by its attracting, or being attracted by, the loadstone, but losing this peculiarity on being reduced by fire to a calx; and retaining it but a short time when perfectly pure. It is the hardest of all metals, not equally malleable with gold, silver, or copper; but more ductile and tenacious. It melts in the heat of 158 of Wedgewood; but our powers of increasing temperature are here limited, and we know not at what degree it boils or evaporates. Its texture is fibrous. By the continuance of a weaker heat it calcines, and more easily, though it melts with more difficulty, than any other metal. If iron is long kept in fusion, it loses its sulphur, becomes more brittle, and at length is converted into a bluish glass; which, if exposed to the heat of a large burning glass, after placing it on a piece of charcoal, becomes iron again. Iron is corroded by a moist air into a reddish yellow rust, occasioned by the oxygen it absorbs, and is soluble in all acids, emitting a garlic odour. Acids precipitate from iron all the common metallic bodies, except zinc, forming with the marine acid a yellow, with the nitrous a dark red, and with the vitriolic a pale green, solution: all salts, except the alkaline, dissolve iron; and this metal by its strong affinity for oxygen decomposes water.

In medicine the distinction betwixt iron and steel, or carbonated iron, is not necessary; but as a medicine, as well as in chemical processes, the softest iron is preferred.

We omitted the chemical properties of iron in the article CHEMIA, because its medical were so intimately connected with them. We shall now previously explain the nature of iron in its different states.

Wrought iron is the metal in its purest form, though

it is seldom perfectly pure. The malleability of the wrought iron is the best test of its freedom from any adventitious substance. Steel is carbonated iron. It usually contains about $\frac{1}{100}$ of its weight of carbon; but it seems capable of combining with a larger quantity, and, in the same proportion, it becomes more brittle. A drop of nitric acid on a plate of steel leaves a black spot; but on a plate of iron, the mark left is a whitish green.

Cast iron contains a larger proportion of carbon; sometimes $\frac{1}{5}$, from whence its colour is blacker, and the metal more fusible; but it is always contaminated with oxide and phosphuret of iron, generally also with flint. This kind is reduced to the state of wrought iron, by exposing it with black oxide of iron to an intense heat. The oxygen and carbon escape in combination.

We have already pointed out the very great affinity of iron for oxygen. According to Mr. Proust there are, however, only two oxides of iron, the black or green, and the red or brown. The first, containing twenty seven parts of oxygen, and seventy-three of iron, is the least oxygenated of the two, and affords a white precipitate, with alkaline prussiats. It is the state of the martial ethiops, insoluble in alcohol, not affected by the gallic acid, and approaches so near that of the metal, as to be sometimes attracted by the magnet, and occasionally to crystallize in octoedra crystals.

The red oxide is composed of forty-eight parts of oxygen and fifty-two of iron. It is the common rust of iron, and, in the old pharmaceutical language, saffron of Mars. It is soluble in alcohol, and gives a blue precipitate with alkaline prussiats, and a black one with galls. With iron filings it is converted, as may be expected, into the black oxide. Sulphurated hydrogen gas, and many other substances, will also take away the superabundant oxygen, and reduce it to the state of the former. Hydrogen dissolves iron sparingly; azote refuses to combine with it; but with sulphur, phosphorus, and carbone, it unites readily. The phosphuret is what the workmen call the cold short (brittle when cold) iron; and was, for a time, supposed to be a new metal, to which the name of *siderum* was assigned. The carburet of iron is the plumbago, or black lead; the well known substance inclosed in pencils. A hypercarburet of iron is hard and unmalleable (Pearson, Philosophical Transactions): red short iron, which is brittle when hot, is supposed to owe this quality to arsenic or to carbon; most probably to the former.

Iron is dissolved in vitriolic acid, forming the green vitriol of commerce; and in the oxide, when combined with an acid, some of its properties just mentioned are only discoverable. Though green, it contains the most oxygenated calx. In the extemporaneous preparation the acid must be largely diluted. Nitric acid rather oxidates than dissolves it; and to obtain the nitrat of iron, the acid must be much diluted. Diluted muriatic acid dissolves iron with violence: the muriat forms in flat, deliquescent crystals. Vegetable acids have a considerable affinity with iron. In the acetic acid it is easily dissolved, and, by its means, iron is suspended in wine. With the tartarous, it forms the soluble *martial tartar*, or *aperitive extract of Mars*; and the oxalate of iron may be easily procured in astringent, deliquescent,

effervescing, prismatic crystals of a greenish yellow colour, soluble in water. Soluble phosphats, added to the sulphats of iron, occasion two new compounds. The phosphat of iron, thus formed, becomes a phosphuret by fusion with powdered charcoal. Prussiate of iron are of a deep, beautiful blue colour: but if the oxide predominates, it is yellow; if defective, green. Carbonic acid unites with the metal, and by its means iron is suspended in the chalybeate waters.

Iron filings, with an equal quantity of nitre, thrown into a crucible red hot, are changed to the yellow oxide of iron, called Zwelfer's *saffron of Mars*: sublimed with muriat of ammonia, it becomes the flores martiales, viz. a muriat of ammonia coloured by iron. This metal is oxidized by agitation in water, and by being digested with either fixed or volatile alkalis.

Iron combined with acids becomes an astringent substance; and upon its astringent, its tonic powers and medicinal virtues seem to depend; for by increasing the tone of the vessels, it increases their vigour and activity. Melampus cured a man of impotency by the rust of iron; which is the first record of its use as a medicine. Boerhaave thinks iron nearer allied to the human fluids than any other metal, and to be almost wholly soluble in them.

We have already remarked that medical utility and solubility in the fluids were too commonly considered as synonymous, and have pointed out the fallacy of the opinion. Iron is undoubtedly an astringent, and perhaps a tonic; since we have reason to think all metallic bodies, except lead, to be tonics. It possesses, however, apparently a quality found in no other metal, viz. a stimulus, by which many of its effects may be explained. One reason has been assigned for supposing it more friendly to the constitution than other metals, viz. the consideration that it is naturally an ingredient in the animal fluids, and that the red globules, whose proportion and vividness are apparently connected with the strength, seem to owe their colour to iron.

The medical uses of iron are almost confined to chronic disorders; in which its efficacy is considerable. In weak, lax, pale, and leucophlegmatic habits it strengthens the stomach, and chylopoietic organs in particular; and by its continued use the whole system is invigorated, the pulse raised, and every mark of health restored.

By the same corroborating power it promotes deficient, and restrains redundant, discharges, where the suppression and excessive flux equally arise from debility; but it increases fluxes, and confirms obstructions when they proceed from tension, rigidity, or spasmodic strictures of the vessels.

An aperient and astringent virtue has been attributed to different preparations of iron; but each is aperient or astringent, according to the state of the constitution of the patient who takes them, without any such property in themselves. Chalybeate waters are said to have similar effects on the constitution as iron. See *AQUÆ MINERALES*.

In the chlorosis, iron, with aromatics, bitters, and aloetic purges, is often very useful. In this, as in most other cases, the crude iron filings, when minutely pulverized, excel any preparation; and are peculiarly proper, as they combine with the acids of the stomach.

The aloetics to be joined with iron in this disorder are the pillulæ ex aloe cum myrrhâ, or vinum aloes: these may be taken not as purgatives, but as eccoprotics, to evacuate the intestinal contents only.

Iron scarcely in any instance occasions dyspnœa. Its ore has, according to Dioscorides, been injected in clysters to restrain diarrhœas; and the water in which hot iron has been quenched is said to be useful when employed as a bath in gout or palsy. In malignant and obstinate ulcers it has been often used with success; and since the article on *CANCERS* was printed, we have found the rust of iron strongly recommended both as a medicine and application in this disease. In roughness and chronic diseases of the skin, it has been recommended; and in the broad brown moles which rise slightly above the cuticle we have known the sulphat of iron highly useful.

It was very commonly employed by the ancients in excessive discharges from the bowels, as in diarrhœa, cholera, lientery, dysentery; and is by many authors recommended as a vermifuge, either operating mechanically as filings of tin, or by its tonic power. In various diseases of debility, besides those already mentioned, it has been employed, viz. in intermittents, in hectic, in dropsies, tympanites, vertigo and pain of the head from relaxation, exhausted powers from venereal indulgences, in gleet; and by some respectable practitioners even in internal obstructions, particularly those of the spleen and mesentric glands.

Suppressed or an immoderate discharge of the menses are relieved by this salutary metal (see *MENSES*); and it is sometimes employed to check hæmorrhoidal discharges. In hypochondriac and hysteric complaints it is highly useful: and many of the true spasms, particularly in epilepsy, it is said to have relieved. We need not repeat what has been said of the tonic power of all the metals; nor what we have remarked respecting the effects of metallic tonics in this last disease. In the rickets it has been recommended; and though in fevers, or where the heat of the body is too great, iron is generally prohibited, yet in some low fevers it hath been administered in conjunction with nitre, it is said, with good effect. In a weak state, when low fever attended, a mixture of sal martis and sal nitri, in equal parts, has been given in doses of ten or twenty grains; but the fever in this case was apparently symptomatic only.

In some instances, iron occasions sickness and perturbation; a mild opiate must then be added, or the medicine taken in bed, half an hour before the hour of rising or of going to rest.

When improperly taken, it sometimes occasions anxiety, head ach, pains in the stomach and bowels, or spasms.

Iron we have said is injurious where the viscera are obstructed, or where an inflammatory tension accompanies it. This medicine should also not be employed when the stomach and bowels are overloaded. It should not be taken a little before or after meals, and be carefully purified from any particles of copper by means of a magnet.

It has been the opinion of some respectable practitioners, and among the rest of Sydenham, that nature affords this remedy in a more useful form than art can supply. We shall therefore first mention the principal

ores of iron employed as remedies. The first of these has had the sounding title of *MINERA MARTIS SOLARIS*. It is the *pyrites* of authors, the sulphurated iron of Haüy, iv. 65, and an astringent of considerable efficacy, as it contains a portion of alumen.

The next ore is the *MAGNET*, the amorphous oxidulated iron of Haüy, iv. 13. It would be endless to transcribe the idle stories recorded of the efficacy of this form of iron. When held in the hand it is said to accelerate delivery; and bound on the body, after being moistened with woman's milk, even Hippocrates tells us that it obviates sterility. Among the graver and more modern authors, whose credulity on this subject is conspicuous, we may mention, as an apology for adding a word on the subject, Baldinger in his *Collection of Dissertations*; Andry and Thouret, in the *Memoirs of the Royal Society of Medicine at Paris*.

Another ore is the *HÆMATITES*, hematite oxidated iron, Haüy, iv. 105; red hæmatites of Kirwan. It was supposed to cure hæmorrhages, when taken internally, held in the hand, or placed under the axilla.

The *RUBRICA FABRILIS*, or *RED CHALK*, has been also employed; it is the red oxidated iron, Haüy, iv. 106; but even the collectors of wonders speak of it only as a good astringent. The last ore is the *ÆTITES*, the eagle stone, a variety of the rusty oxidated iron, Haüy, iv. 107, called *geodic*. A geode is a round body with a cavity within, usually full of water or earth. This ore also takes away labour pains and prevents abortions!!

The preparations in general use are the following:

Limatura ferri.—FILINGS OF IRON, called also *duenez*. Of all the preparations, this alone is said to possess all the virtues of iron. The rust is not so powerful an absorbent of acid in the primæ viæ, nor does it yield so large a share of the gas, separated by the action of acids on pure iron, which some authors have supposed to be useful. If pure iron be reduced into fine filings, it is the least offensive to the taste, and the most extensively advantageous.

A preparation between this, and the rust of iron, which follows, is the black oxide found in scales round a smith's anvil. This was the form recommended by Dr. Black, and on the whole is the most useful. Iron wire, as made of the purest iron, is often preferred; but the hydrogen gas separated from the metal, when not oxidized, often produces inconvenience, so that the scales are preferable.

Ferri rubigo.—THE RUST OF IRON. Moisten clean filings of iron with water, and sprinkle them over with a little powdered sal ammoniac; when the whole is dried, powder and pass it through a fine searse. The dose is the same as that of pure filings. The college of physicians of London order one pound of iron filings to be exposed to the air, often moistened with water until they are corroded into rust; then pounded in an iron mortar, and the very fine powder to be washed off with distilled water. The remainder is easily separated by washing, and must undergo the same process: the prepared powder must be dried for use. Pharm. Londin. 1788. In hypochondriac and epileptic complaints, in worm cases, and in weak relaxed habits, it has proved useful. The Dublin college prepare it from iron wire, as the purer form of the metal.

The following electuary is not an inelegant form of

administration. R. conserv. absinthii maritimi, $\bar{3}$ i. rubiginis ferri, $\bar{3}$ ss. cons. ari. $\bar{3}$ ij. corticis aurant, q. s. During the continuance of taking this medicine the body should be kept open by some gentle aperient medicine.

Flores martiales.—MARTIAL FLOWERS; formerly *ens veneris*, now *ferrum ammoniacale*, are prepared by mixing of iron filings, one pound, with sal ammoniac, two pounds. Sublime them, and what remains mix, by rubbing together with the sublimated matter; and again sublime. Pharm. Lond. 1788.

The success of this process depends chiefly upon the fire's being hastily raised, that the sal ammoniac may not sublime before the heat is become strong enough to enable it to carry up a portion of the iron; hence earthen or iron vessels will be most proper for the purpose. The most convenient vessel is an iron pot, to which may be luted an inverted earthen jar, with a small hole in its bottom to allow the elastic vapours which arise during the operation to pass off.

When these flowers are impure, they are of a dull and pale yellow colour; but they may be purified by sublimation.

The Edinburgh college directs this medicine to be prepared by mixing equal weights of the red oxide and muriat of ammonia. This mixture is sublimed. In this preparation there is only a single decomposition; and the muriat of ammonia is decomposed by the metal, which only takes place in high temperatures. Some unchanged muriat of ammonia comes over, so that the sublimate must be carefully mixed after the operation. In both processes the proportion of iron is too great. It is only required to be $\frac{1}{16}$ of the muriat. A tincture is prepared from these flowers, by digesting four ounces of ammoniacal iron in a pint of proof spirit.

The dose is from gr. vi. to $\bar{3}$ i. The *flores martiales* are considered as deobstruent and corroborant; and if given in pills must be combined with the fetid gums. They may be substituted for all the other preparations of iron; but are by no means particularly powerful.

From these flowers, dissolved in warm water and precipitated with the aq. kali, is produced the *Mars diaphoreticus*, and by Zwelfer, *sulphur vitrioli anodynum martiale*; dissolved in sp. vini rectificatus, they form the *sedativum archæi*.

4. *Vinum chalybeatum*. *Vinum ferri*.—Take four ounces of the filings of iron; of cinnamon and mace, of each half an ounce; and of Rhenish wine, four pints. Macerate without heat for a month; then strain off the wine for use. The college of London orders four ounces of the filings of iron to be digested for a month in four pints of Spanish white wine, often shaking the vessel, and then strained. Phar. Lond. 1788. The Dublin college substitutes, for the filings, iron wire, and for Spanish white wine, Rhenish wine. The strength of the preparations are unequal, and a better, as well as a more certain medicine is a solution of tartarized iron.

Solutions of iron in vegetable acids are much more mild, and less ungrateful, both to the palate and stomach, than those made with the mineral acids.

The dose is from a tea spoonful, to a table spoonful, two or three times a day. In chlorotic cases, and in debilitated phlegmatic habits, it is an excellent remedy; but in inflammatory habits should be cautiously administered.

Tinctura martis in spiritu salis.—*Tinctura ferri muriati.* Take of the rust of iron, half a pound; muriatic acid, by weight, three pounds: pour the muriatic acid upon the iron in a glass vessel, and shake the mixture now and then, during three days; set it by, that the fæces may subside, evaporate the liquor poured off to one pound, and add three pints of the rectified spirit of wine. Pharm. Lond. 1788.

The Edinburgh college employs the scales of iron or the black oxide; and the Dublin iron wire. The first and last are therefore nearly the same, and very different from the London formula, in which the red oxide is used. The red muriat is, however, only soluble in spirit of wine; and some of this muriat is formed both in the Edinburgh and Dublin forms.

This was formerly called *tinctura martis Mynsichti*. Its virtues are the same as of other preparations of iron; but it is generally more speedy and certain in its effects: its dose, from ten to sixty drops, two or three times a day. It has sometimes been given for gleet; and in suppressions of urine, arising from spasmodic affections of the urethra, in a dose, ten drops every ten minutes till some effects are perceptible: it relaxes the spasm by producing nausea. It is very efficacious in destroying venereal warts, either used alone, or diluted with a small proportion of water.

Tinctura florum martialium.—Take of the martial flowers, four ounces; and of proof spirit, one pint. Digest and strain.

All the tinctures of steel are no other than real solutions of iron in acids, combined with vinous spirits; but the first of these two is the strongest. The dose of the first may be from ten to twenty drops three times a day; and of the latter, three times the quantity may be allowed.

Carbonas ferri precipitatus is the name of a preparation introduced into the last edition of the Edinburgh Dispensatory, usually styled the *ferrum precipitatum*. It is prepared by dissolving four ounces of sulphate of iron, in five quarts of water, and adding five ounces of carbonate of soda, dissolved in a sufficient quantity of water. The iron precipitated is, at first, in the form of the black oxide; but it attracts more oxygen in drying, and becomes of a red colour. It is a valuable medicine, and may be given from five grains to fifteen; but the former dose is generally sufficient. The carbonate of soda is employed; as the salt, which results from the double decomposition, is very soluble, and of course easily separated.

Aqua ferri aerati is introduced into the Dublin Dispensatory, and is made as the artificial acidulous water, introducing into the vessel half an ounce of iron wire, and suspending it in the water. This is an elegant chalybeate, and by no means inferior to the Pyrmont water.

Sulphas ferri exciccatus, and *oxidum ferri rubrum*, are preparations introduced into the last Edinburgh Dispensatory. In the first, the water of crystallization only is separated by a gentle heat; and in the last, the sulphat of iron is decomposed by a violent fire. A little red sulphat remains, which must be separated by elutriation.

Tinctura ferri acetati is directed by the Dublin college to be prepared in the following manner. An ounce of acetated vegetable alkali is rubbed with as much vitri-

olated iron till the mass deliquesces. Alcohol is then added. The process is easily explained; and the tincture is a solution of the black oxide, unless it gain some oxygen in the preparation. The sulphat of potash, formed in the process, is not soluble in alcohol; so that the tincture when filtered has no saline impregnation, except that of the iron. The dose is thirty drops.

Lixivium martis.—Let the substance remaining after subliming the flowers be set in a moist place, and it will deliquesce. It is sometimes called *oleum martis per deliquium*, and *essentia martis*. The dose is from one to three or four drops. It is an astringent, and a very powerful one. In surgery it is used as a styptic, and in cases of hæmorrhage applied to the bleeding vessels on lint.

Mars saccharatus. CANDIED STEEL.—Put any quantity of clean filings of iron into a brass kettle, suspended over a gentle fire; add to them, by little and little, twice their weight of white sugar, boiled to the consistence of candy, with which powdered starch hath been previously mixed, in the proportion of one drachm to a pound, agitating the kettle continually, that the filings may be crusted over with the sugar, and taking great care to prevent their running into lumps. The dose is ʒss. two or three times a day.

Mars solubilis, chalybs tartarisatus; now ferrum tartarisatum.—Take of iron filings, one pound; powdered crystals of tartar, two pounds; mix them with distilled water into a thick paste; expose them to the air in an open earthen vessel for eight days; and then rub the matter, when dried in a sand bath, to the finest powder. Pharm. Lond. 1788. This is said, to have succeeded after all other preparations of iron have failed; and is supposed to be more soluble in the animal fluids. The dose is from ten grains to thirty, twice a day. It is in fact a triple salt, as potash is combined, and the filings of iron are oxidized by exposure to the air. A more ready way of preparing it is that proposed by Thenard, viz. to boil the cream of tartar with an oxide of iron. This compound is very soluble, crystallizes in small needles, and has a chalybeate taste. It is decomposed by sulphurated hydrogen and its compounds, as well as by the gallic acid, not by alkalis, or alkaline carbonats.

Sal martis. SALT OF STEEL. *Chalybis sal*, now called *ferrum vitriolatum*. VITRIOLATED IRON.—Take filings of iron, vitriolic acid, by weight, of each eight ounces; distilled water, three pints; mix them in a glass vessel, and when the effervescence has ceased, place the mixture for some time on hot sand; then pour off the liquor; filter it through paper, and after proper evaporation let it crystallize. Pharm. Lond. 1788. It is given from three or four grains to twenty; is supposed to quicken the circulation, give tone and vigour to the system, and destroy worms: ten grains may be dissolved in a pint of water, and given in repeated draughts, with proper exercise, as a chalybeate water.

Extractum martis.—Iron filings are to be dissolved in some vegetable acid, and then evaporated to a due consistence.

For the *crocus martis aperiens*, and *crocus martis astringens*, the college of London substitutes the colcothar vitrioli. They are all the red calx of iron, and the least active of the chalybeates. M. Beaumé observes, that these calces recover their metalline state by digesting in olive oil during an hour or two.

As usual, we shall add a short account of those preparations of iron which have been commended by former authors, and particularly the practitioners on the continent, at present disused in this kingdom. The *croci martis* merit a little further notice in this part of the article. They have been differently prepared, and had many different appellations, according to the fancy or object of the chemist. Sometimes the iron has been calcined by fire, sometimes by acids, and occasionally by moistening it only, when it does not differ from the *rubigo ferri*. Iron calcined by fire gives the *crocus martis obstructivus*; deflagrated with common salt and nitre, or nitre and sulphur, it is the *pulvis cachecticus* of Boecler. If a piece of sulphur is rubbed on a hot iron, and the drops suffered to fall into cold water, it affords the *crocus martis aperitivus* (*crocus martis niger*, and *chalybs cum sulphur preparatus*). The *crocus martis sulphuratus* (*chalybs* and *Mars sulphuratus*) is made by stratifying filings of steel with sulphur in different proportions, moistening the mixture till it grows hot and swells. It is then powdered and subjected to a violent heat with continual stirring, till it becomes a black powder. When still further heated, to separate the whole of the acid, and further to calcine the iron, it becomes red, and is then the *crocus martis aperiens*. When further heated, it is converted to a mere calx, and is the *crocus martis astringens* (*adstrictorius* of Sala). It will be obvious that the calces, in all these tedious preparations, are only in the progressive state, from the black to the red oxide, formerly described, and differing little from the common calces of iron.

In various foreign pharmaceutical works, the rust of iron is differently prepared, without seemingly altering its properties. The filings of steel are sometimes moistened with dew, with vinegar, with urine, particularly of boys, solutions of common salt, (*crocus martis emenagogus*;) of borax, or tartarized tartar: sometimes the different mineral acids are employed either in the forms of fluid or vapour, and the rust then acquires other properties. From these it is precipitated by alkalis, particularly caustic ones, or the acid is expelled by heat. By repeating these processes, Schroeder obtained a *crocus chalybis ruber*, which he highly commends. A *crocus martis* is also obtained by agitating the iron in carbonic acid water, vinegar, or a highly diluted nitric acid, washing the paste which results, and drying the light powder which subsides.

The *Mars solubilis alcalisatus* of the old, and particularly Lewis's Dispensatory, differs little from the tartarised steel already described. The *globuli martiales* differ only in containing a smaller proportion of the acid, and are employed externally in contusions, luxations, and gun-shot wounds.

The *acetis ferri* is directed only by the Dublin college as the basis of a tincture. The substance is ordered by the Wirtemberg college; and the tincture is sometimes denominated from Radcliffe. It is usually prepared from the filings of steel, or the martial ethiops, united with the vegetable acid; and is highly commended by Boerhaave as a tonic and anthelmintic, particularly as an antirachitic. When inspissated, it is styled *extractum martis*.

Tinctura martis cydoniata is particularly described by Wedelius, and usually exhibited with spirituous cinnamon water. We find it commended in the same dis-

eases as are supposed to be relieved by the other chalybeates, and particularly in puerperal discharges. The *tinctura martis pomata*, a solution of iron in cyder, and the *tinctura martis cum vino malvatico* and *pomis aurantium*, are similar medicines of no peculiar qualities. The two first are sometimes inspissated into an extract. The last is a very weak, inert preparation.

Tinctura nervina of Bestuchef; *tinctura nervino tonica flava*; *guttæ aureæ Lamottii*, *liquor nervinus albus*, *liquor anodynus martialis*, are the appellations of a secret medicine, purchased by the empress of Russia, and published. This tincture is generally of a beautiful golden colour if exposed to the sun's light, which is lost in the shade, and returns again in sunshine: it deposits a blue sediment by the addition of the Prussian alkali; and is, like the other tinctures of steel, a tonic. It is a vitriolic ether, with a portion of spirit of wine, holding in solution muriated iron.

The last preparation which we shall mention is the *serum lactis chalybeatum*, prepared by quenching hot iron in whey. It is commended as a tonic; but we can find no very distinct account of the diseases to which it is peculiarly adopted.

See Lewis's *Materia Medica*: Neumann's *Chemical Works*.

FE'RRUM AMMONIA'CALE. See FERRUM.

FE'RRUM EQUI'NUM. HORSE SHOE VETCH. *Hippocrapis uni siliquosa* Lin. Sp. Pl. 1049. Dale adds that all the species are astringent.

FE'RRUM TARTARIZA'TUM. See FERRUM.

FE'RRUM VITRIOLA'TUM. See FERRUM.

FE'RSÆ. MEASLES, *a fervore*, from the heat which accompanies them. See MORBILLI.

FE'RRULA, a STAFF, which it resembles. FENNEL GIANT. It hath a large, succulent, milky root; the stalk is fungous, and full of a pitchy matter.

FE'RULA AFRICA'NA GALDANI FERA, FRUTICO'SA, SEMPE'RVIVENS. See GALBANUM.

FE'RULA ASAFÆTIDA. See ASAFÆTIDA.

FE'RULA FO'LIO BREVIO'RI. See MEUM LATIFOLIUM ADULTERINUM.

FE'RULA GLAU'CO FO'LIO, &c. called *thapsia ferulacea*, *libanotis feniculi folio*, *panax asclepium*; *thapsia asclepium* Lin. Sp. Pl. 375. CANDY ALL HEAL. This species grows in Candy; its roots and seeds are diuretic and emmenagogue.

FE'RULA SEU FÆ'MINA; FE'RULA TENUIORE FOLIO; FE'RULA FENICULI FOLIO. FENNEL GIANT. *Ferula communis* Lin. Sp. Pl. 355. It is cultivated in gardens, and flowers in July. See SAGAPENUM.

FE'RULA MI'NOR, called also *panax asclepium*, *ferula facie*, *libanotis ferula folio et semine*; *ferula nodiflora* Lin. Sp. Pl. 356. All-heal of Esculapius.

FESTU'CA AVENA'CEA, (from *fero*, to bear; so called from resembling the young shoot of a tree,) FESTUCA. THE GREAT WILD OAT GRASS. See ÆGYLOPS.

FI'BER. See CASTOR.

FI'BRA, (from *fiber*, extreme). A FIBRE. Haller observes, that the least discoverable fibres are of two kinds. The first are lineal; the second are conjoined with a breadth frequently larger than their length; and the latter, he informs us, are those of which the cellular membrane is made up.

On the different proportions of the terrestrial matter,

and the gelatine which forms the simple fibre, depend probably their different degrees of cohesion, and from hence Boerhaave deduces the general source of diseases. See Boerhaave's Aphorisms, and Haller's Physiology, under the title of ANIMAL FIBRE.

Each of these opinions, however, is fallacious; and indeed, when we speak of the cellular substance as a fibre or a membrane, we convey ideas which mislead. The human body seems to be originally fibrous. At the earliest period when the embryo can be subjected to our senses, it seems to resemble the tadpole, with a tail only extended from a rounded head. There appears to be little doubt of this being exclusively the brain and spinal marrow, for the lower extremities are developed at a much later period. If this be true, the fibrous structure of the human body is only the nervous system; on *its fibres* are deposited the nutriment formed in successive eras by the powers of the constitution, and these direct the form and the shape of the different parts of the body. In reality, this is the *moule interieure* of which Buffon so often speaks. This system, which we hope to render more probable in other parts of the work, requires that the productions of this aboriginal nervous germ, viz. the nerves, should be convoluted within a small space, capable of a certain degree of extension, different according to the organs which they are to form or supply. Beyond this power of extension, or, in other words, their length, the organ cannot expand; and the different extent of the nerves, in each part, depends on the individual constitution. This theory involves no contradiction, scarcely any difficulty, except the extreme minuteness of these fibres; but minuteness is only relative, and will disappear, if we reflect that even the mite probably nourishes some parasitic animal, and that this last must possess vessels, arteries, and muscular fibres, peculiarly its own.

According to these views the fibrous parts of the human body are the nerves, the muscles, the blood, and absorbent vessels; consequently the great bodies of the glands, as composed of vessels and membranes. The other parts are the cellular substance, which is only a connecting medium, and which, in every instance of adhesive inflammation, is formed before our eyes.

The diseases of the fibres are only those from too great rigidity or laxity; but, if we consider these as nervous, or prolongations of the brain and spinal marrow, we shall reduce them to excessive tone and relaxation. The connection between the state of the simple fibres and the nervous system we have already noticed at sufficient length. See ASTRINGENTIA.

The strength or weakness of a fibre is wholly relative. Soon after conception the cohesion may be destroyed by the slightest touch; but the cohesion increases till the degree is attained which gives perfection to the being. The perfection of cohesion is when a fibre will bear a greater force than what its state and office regularly require. Many, though equally unsatisfactory, are the rules laid down to distinguish betwixt the rigid and lax fibre, in particular constitutions; but with a view to practice, a rigid fibre is a concomitant of strength, and the lax fibre of its deficiency.

FIBRO'SUS, (from *fibra*, a fibre). In botany it is applied to the root, and means consisting of small strings.

FIBULA, (quasi *figilula*, from *figo*, to fasten). A

BUCKLE, CLASP, or BUTTON. It is the name also of an ancient mode of bringing the lips of wounds together. Hippocrates sometimes uses the word for the part of the bone that forms the outer ankle, perhaps, because the shoes were buckled in that place. The ancients gave this name to the small bone of the leg, from its joining the tibia and muscles together: it is also called *perone*, *facile minus*, *arunda minor*, *canna minor cruris*, *sura*, and *radius*. On the outside of the leg, and behind the tibia, the fibula is placed: its upper extremity is flattened where it is connected to the former; and its lower extremity hath an oblong head, received by the external cavity of the tibia; below this the head of the fibula is extended in a coronoid process, the malleolus externus contiguous to the outside of the astragalus.

The arterics of all the long bones run obliquely into them, and as they thus resist the action of styptics, their wounds occasion obstinate hæmorrhages. It is remarkable that in this oblique course the arteries of the os humeri, tibia, and fibula, run obliquely downwards; those of the radius and ulna upwards: a structure seemingly designed to facilitate the circulation from gravity, as the arteries confined by the bone cannot contract. The radius and ulna are, it may be remarked, occasionally raised.

FIBULE'US, (from *fibula*, the small bone of the leg). See PERONÆUS MUSCULUS LONGUS.

FICA'RIA, (from *ficus*, a fig). See SCROPHULARIA MAJOR, and CHELIDONIUM MINUS.

FICA'TIO, (from the same). See FICUS.

FICOIDES, (from *ficus*, and *ειδος*, likeness). A succulent plant, resembling the fig tree, supposed to be emollient. *Ficoides* is also a name of the banana.

FICUS, vel FICA'TIO, (from *φω*, to produce; or *phig*, Hebrew). The name of a tubercle about the anus or pudenda. See CONDYLOMA.

FICUS I'NDICA. See BANANA and MUSA.

FICUS I'NDICÆ GRA'NA. See COCINILLA.

FICUS I'NFERNALIS. See CATAPUTIA.

FICUS SATI'VA, ARIDA, COMMUNIS. The FIG TREE. *Ficus carica* Lin. Sp. Pl. 1513. The unripe fig is called *grossus*; the dried, *carica*; its grain or seed *enchramis*, from its resembling millet seed. This tree is of a middling size, with large leaves cut into five segments; grows spontaneously in the warmer climes, and is cultivated in our gardens.

The best figs are brought from Turkey; many from the south of France, where they dry, after dipping them in hot ley, made of the ashes of the fig tree, by exposing them to the sun. The recent fruit, completely ripe, is soft, succulent, and easily digested, unless eaten in immoderate quantities, when it is apt to occasion flatulency, pain of the stomach, and diarrhœa.

The skin of the fruit is glutinous and salt; and from hence their laxative power has been ridiculously derived. They are very nutritious, as their sugar is united with a large portion of mucilaginous matter; grateful to the stomach, and easier to digest than many other of the sweet fruits. But they are used in medicine as a lubricating emollient, and are an ingredient in pectoral decoctions, as well as suppurating cataplasms. They are sometimes used alone, and applied as warm as they can easily be borne to phlegmons of the gums, and other parts where poultices cannot be confined. See Lewis's and Cullen's Materia Medica.

FIDICINA'LES, (from *fidicen*, a harp). Some muscles of the fingers, particularly used in playing upon the harp, and other stringed instruments. See LUMBRICALES MUSCULI.

FILACE'Æ RA'DICES, (from *filum*, a thread). FILACEOUS ROOTS; such as are furnished with many thread-like filaments.

FILA'GO, (from the thread-like filaments of its leaf). See GNAPHALIUM.

FILA'GO ALPINA. The herb LION'S FOOT. See LEONTOPODIUM.

FILAME'NTUM. A FILAMENT, (from *filum*, a thread, of the diameter of a slender thread). In botany it is that thread-like part of the stamen which connects the anthera with the receptaculum. By some English botanists it is called thread.

FILE'LLUM, (from *filum*, a thread). See PENIS.

FILE'TUM, (from the same). See LINGUA.

FILICES, the plural of *felix*, (from *filum*, a thread; quasi *filatim incisa*). FERNS; one of the natural orders of the vegetable kingdom, having the fructification on the back side of the leaves. They constitute the first order in the class *cryptogamia*, and consist of sixteen genera divided into fructifications spicatæ, frondosæ, and radicales.

FILI'CU'LA, a dim. of *felix*, fern). A small sort of fern; also the herb MAIDEN HAIR, (from *filum*, a thread, which it resembles). See ADIANTHUM NIGRUM.

FILIPE'NDULA, (from *filum*, and *pendeo*, to hang, because the numerous bulbs of its root hang as it were by small threads). DROPWORT; *saxifraga rubra* and *ananthe*. It grows wild in fields and chalky grounds, is rough and bitter, and slightly pungent. The species used in medicine is the *spiræa filipendula* Lin. Sp. Pl. 702.

FILIPE'NDULA CICU'TÆ FA'CIÆ. See CENANTHE CHEROPHYLLI FOLIIS.

FILIUS ANTE PA'TREM. THE SON BEFORE THE FATHER; because the flowers appear before the leaves. TUSSILAGO is one of these plants, q. v.

FILIX. See FILICES, its plural. *Pteris*. FERN. *Blancnon Oribasii*.

Fern is divided into the male and female; the male hath no branches, but only one main rib; the female is branched.

FILIX ACULEA'TA. See LONCHITIS.

FILIX FLO'RIDA, RAMO'SA, *osmunda vulgaris*, and *palustris*. FLOWERING FERN and OSMUND ROVAL. *Osmunda regalis* Lin. Sp. Pl. 1521. It is the largest of the true English ferns, bears no flowers, and its fruit in clusters. Towards their tops are round, slender, seed-bearing, curled heads of a brownish colour, covered with seeds: they appear in June, ripen in July, and are chiefly found in marshes. The roots consist of many small parts, matted together, blackish on the outside, and green within, covered with small fibres: they are equal in power to the roots of the other ferns; but a conserve of the tender buds or heads is preferable.

FILIX FÆMI'NEA, RAMO'SA MA'JOR. FEMALE FERN, BRAKES, or BRACKEN. *Pteris aquilina* Lin. Sp. Pl. 1533.

FILIX FO'LIIIS POLYPO'DII. See POLYPODIUM ANGUSTIFOLIUM.

FILIX MAS. MALE FERN, called also *lonchitis*; *polypodium filix mas* Lin. Sp. Pl. 1551. The root of the

male fern resembles that of the *osmunda regalis*, and is often sold for it. The roots of most of the species, when chewed, are of a sweetish taste, glutinous, but soon become bitterish, subastringent, and nauseous: they are used for destroying the tænia, and given in the following manner: the patient is first prepared by an emollient clyster, and a supper of panada, with butter and salt; in a morning, two or three drachms of the powder of the male fern root are given, washed down with a draught of water; and, two hours afterwards, a strong cathartic, composed of calomel and scammony, proportioned to the strength of the patient. To assist its operation, if necessary, a dose of purging salts may be given; and, if the worm is not expelled in a few hours, this process, at proper intervals, must be repeated. Dr. Cullen thinks it doubtful whether the ferns have any specific power in killing worms; for the stomach bears considerable quantities without uneasiness; and, alone, it has no sensible effects: its apparent benefit may, therefore, be derived from the drastic purge. In Germany, however, the tænia has been expelled by the repeated exhibition of the root, without the aid of any purgative; and it is possible that a medicine may be poisonous to worms, that has no effect on the human body. We have found that portions of tænia, before discharged alive, have, after the exhibition of the fern root, no longer shown signs of animation. The fern root has been used as a deobstruent, and been extolled against the rickets. The male fern, and those that bear flowers, are most powerful as antiseptics and astringents; the female fern is more viscid, saponaceous, and diuretic. Cullen's *Materia Medica*. Woodville's *Medical Botany*.

FILIX QUE'RNA RE'PENS. See POLYPODIUM TENERUM MINUS.

FILTRA'TIO, (from *filtrum*, a strainer). See DEPURATIO. Generally a paper is folded into the shape of a funnel, and then placed in one; through this the liquor passes, and the feculencies are separated.

FILTRUM. (See FILTRATIO.) A stone found in the bay of Mexico, through which liquors are filtered, and particularly turbid or impure water. Flints powdered to different fineness are sometimes introduced into a cylinder for the same purpose; and occasionally the weight of a descending column of the fluid is employed to propel it through the natural or artificial pores of the filtre.

FILUM ARSENICA'LE. See MERCURIUS CORROSIVUS ALBUS.

FIMBRIA, (quasi *finibria*, from *finis*, the extremity). FRINGE. Those leaves are said to be fimbriated that are jagged about the edges. In surgery this word is synonymous with CATABLEMA, q. v.

FIMBRIA'TUS. See FIMBRIA.

FIMMUS, (from *fo*, to make). DUNG. The dung of many animals hath been used; but the present practice excludes them all. That of dogs is an absorbent.

FISSILIS LA'PIS HIBE'RNICUS, (from *fissus*, cleft, because it is divided into thin layers). *Fricus*. See HIBERNICUS LAPIS.

FISSURA, (from the same). A FISSURE or CRACK. The mouth, or other natural apertures into the body, are called *fissures*; but morbid fissures are cracks in the skull, or in a long bone when the fracture is longitudinal.

A morbid fissure differs from a fracture, because in the latter there is a total solution of continuity. A fracture also is transverse or oblique; a fissure longitudinal.

Fissures most frequently occur in the skull; and of these there is, first, the counter fissure, when the blow is received on one side of the head, and the fissure is on the other; where the internal table is broken, the external remaining sound; or where the stroke is received on one bone, and the fissure is in that adjoining. Many authors doubt the existence of a counter fissure, and it is difficultly accounted for; but the facts are well attested. Hippocrates, Galen, Celsus, Berengarius, Fallopius, and several others, assert their having met with such instances. The most frequent kind is that which is soon discovered by laying the bone bare, and cleaning the part with sponge; but they are occasionally so small, that some art is necessary to discover them. If a black liquor, made of burnt bone or cork, mixed with water, is rubbed on the bare skull, it will sink into the crack, and discover, when washed off, its situation; or, if the head be clean shaved, and the patient bled freely, an œdematous puffiness will appear, in a day or two, over the part affected.

Fissures are often productive of worse consequences than fractures; for there is often, at the same time, a concussion of the brain; and it is consequently necessary to ascertain this circumstance. Instances of the ill effects of fissures have happened many months after the accident. The fissure alone is not dangerous, but the violence which occasioned it, and the consequent rupture of numerous vessels, whose extravasated contents injure the bone. When this happens, an unexpected death is often the consequence.

Trepanning seems to be the properest method of relief; though the plan recommended by Mr. Bromfield, in concussions of the brain, has alone effected a cure.

FISSURA CEREBRI MAGNA SYLVII. The sulcus which divides the anterior and middle lobes of the cerebrum on each side: it ascends obliquely backwards from the temporal ala of the os sphenoides to near the middle of the os parietale.

FISSURÆ ORBITARUM INFERIORUM. See SPHERO MAXILLARUM FISSURÆ.

FISTULA, (quasi *fusula*, from *fundo*, to pour out). So the Latins called a catheter. See CATHETERUS; and also a *clyster pipe*. See ENEMA.

FISTULA. A PIPE. In surgery it is a kind of ulcer which resembles a pipe; named also *eligi morbus*. It is narrower than a sinus; generally continues further; hath its internal surface and its orifice usually callous; and is generally the consequence of abscesses. The seat of a fistula is in the cellular membrane. It is known to be present when there is an aperture on the surface of the body from which any matter either flows or may be pressed out: its depth and direction are discovered by a probe; or, if the directions are various, warm water may be injected into it; and, if near the skin, these will be ascertained by the elevation occasioned by the water; if otherwise, the quantity of water retained will determine the size of the cavity. The probe often discovers whether the fistula runs upon an adjacent bone, or whether the bone be carious. The parts in which these ulcers are seated, and their various circumstances, constitute the chief differences betwixt

fistulæ. A fistula is more dangerous in proportion to the depth of the cellular membrane, and the thickness of the muscles. While it is simple, and extends no further than it can be reached with a knife, it may be generally cured: when so situated as to open into the neck of the bladder, or when attended with a caries in the adjacent bone, particularly the os sacrum or the coccyx, the cure is difficult, and often impossible.

Mr. Bell includes the fistula in his species of sinous ulcer; by which he means that kind of sore which hath one or more openings running into it from the same or different directions, and generally seated in the cellular membrane. A sinus, as thus described, he says, is the most simple state of the disorder, and is, by long continuance, or by the use of drying astringent applications, liable to become hard and callous in its internal surface, and in such a state, from its supposed resemblance to a pipe, is termed a fistula. The most frequent cause of sinuses in ulcers and abscesses, is the want of vent or a sufficient opening for the discharge, which easily insinuates itself into the yielding substance of the cellular membrane, and proceeds gradually till it finds an opening either externally or into some of the neighbouring cavities. An improper application of bandages on ulcers is often the cause of a sinus.

When fistulas, not yet become callous, are complicated with ulcers, the most expeditious relief is from an incision to the bottom, if it can be done without danger: after which the wound is to be cleaned and healed. Another method is, to compress the fundus of the sinus; for which purpose a narrow compress, or a slip of plaster wrapped up in that form, is to be applied externally over the bottom, and secured, as in other ulcers, with a plaster and bandage, that the peccant matter may be propelled from the bottom to the mouth of the fistula, that the former may be soonest healed. This happens most frequently when the fistula is in the arms or legs, or when its orifice is lower than its fundus. Belloste, and some other surgeons, reject all tents and injections; but when fistulas lie deep, detergent injections must be used. These are a decoction of birthwort, mixed with honey of roses, or with the tincture of myrrh and aloes: they must be injected warm at every dressing, and retained for a short time; the bottom and mouth of the fistula are gently pressed, that the matter may more effectually be washed off. This method must be continued until the bottom of the fistula begins to heal. It may then be dressed with some soft digestive, of which the balsamum Peruv. or balsamum capivi are ingredients. When this method fails, the operation must be attempted; but it is not to be depended on, except when the opening can be carried to the bottom of the ulcer. The incision is made with most ease to the patient with a knife; and whatever instrument be used, the incision must be so deep as will be sufficient to answer the end; for when the bottom is laid open, the matter is not only discharged, but medicines more commodiously applied. If, upon making the incision, a large quantity of blood is discharged, fill the wound with dry lint, and proceed as is usual in recent wounds. Mr. Bell advises almost universally to avoid the practice of laying the different sinuses open from one end to the other, and cutting out all the hardened parts, so as to convert the whole into one common ulcer. This method he owns will frequently effect a cure; but inde-

pendent of the great pain, and very large unseemly cicatrix occasioned, it cannot, in every case, be safely practised. When sinuses, for instance, run far up the rectum, it cannot ever be conveniently done; they penetrate deep, and run below either large blood vessels or nerves: in these cases such treatment cannot be advised. The object in every case of sinus, is to produce a coalescence of its sides, so as to destroy any vacuity that may have occurred; and the most effectual means of accomplishing it is, to make a depending orifice for a free exit to the matter; or by a gentle irritation, to induce, on its internal surface, a slight degree of adhesive inflammation; so that a firm union of the sides of the sinus may be obtained. To answer both these intentions, Mr. Bell thinks that the introduction of a seton is sufficient. The seton must pass from the orifice in the ulcer along the course of the sinus to its other extremity, where an opening, large enough for the discharge, should be made, as in cases of abscess. The cord of cotton, or of silk, should at first be large in proportion to the capacity of the sinus, and diminished gradually as the cure advances. When the discharge is greatly lessened, by the diminution of the vacuity, the seton should be totally withdrawn; a bandage somewhat tight applied over the part, and continued till a complete cure is effected. In this process the first step is, to discover the direction of the sinus, or sinuses; which may commonly be done either by introducing a probe, observing where the matter points, or allowing the matter to collect, and remarking from whence it comes when the parts are pressed: then into every sinus which opens into the ulcer a seton should be introduced. This method of curing sinuses, by the use of a seton, is free from all danger, and may be employed in all cases of this kind; for a seton, by means of a director, may always be used with safety. The sinuses being removed by the setons, the ulcers connected with them are to be cured in the way appropriated to each kind. This practice rarely fails in any case of simple sinus; in general it answers in real fistulæ; and for a fistula in the perinæum this practice is peculiarly advantageous, as it does not produce that troublesome cicatrix which follows the use of the knife. The only objection to the use of the seton in cases of fistula in ano, is the irritation it would occasion in the gut; but of these we must next speak. See Celsus, lib. vi. c. iv. Boerhaave's Aphorisms, the English translation, pp. 102, 103. Pott's Treatise on Fistulas. Bell's Treatise on Ulcers, edit. 3, p. 244, &c.

FISTULA IN ANO. No part of the body is more subject to abscesses than that immediately surrounding the lower part of the rectum: it is much exposed to pressure and other external injuries, which impede the free motion of the blood; and, in parts where the circulation is so languid, obstructions soon occur, and purulent matter is formed with little appearance of active inflammation. We sometimes find also a metastasis to this part; and there are anomalous cases of hectic which seem to originate from an affection of the liver, where this metastasis is not uncommon. As the skin is pretty thick around the rectum, the pus will insinuate itself amongst the soft neighbouring parts, and form sinuses, which degenerate into fistulæ.

This kind of fistula is called complete when there is an opening into the gut, and another externally; incomplete when there is no external aperture.

The symptoms of the incomplete kind are analogous to those of the piles, and are difficultly distinguished from them. The complete kinds have generally callous lips, which, with the discharge, more readily points out the nature of the case.

Abscesses in this part should be opened as soon as we find a fluctuation of matter, and by a large aperture, most effectually to prevent a return. In examining one of these fistulas, if the probe does not readily pass, warm milk may be injected into it, to see if any returns by the rectum, and of course to discover if the gut is perforated. When the probe is used for the examination, let the patient stand on the ground, with his feet pretty far asunder, and lean on the belly over a table: an assistant can then hold his buttocks asunder, that the operator may more readily introduce his finger into the anus before he examines the fistula with a probe. If the fistula runs so deep that the finger introduced into the anus cannot easily reach the orifice, the cure is doubtful, and the attempt dangerous, on account of the hæmorrhage from the vessels, which admit not either of compression or ligature. If a fistula hath been of long standing, in a bad habit, and the discharge is such as to weaken the patient, the operation should not be attempted, at least till the constitution is repaired; but if the patient is of a good habit, if the fistula returns, the operation may be repeated.

We have just remarked also that a fistula is sometimes connected with diseases of the liver or the lungs, and in these cases it appears to be a critical discharge. If any cough or hectic fever has preceded, the operation soon hastens the fatal termination. The hectic recurs with increased violence, the purulent expectoration is more copious, and the strength rapidly fails. The appearances which contraindicate the operation, are those only which are pulmonary; but the true hectic, viz. where the lungs alone are affected, seems seldom, if ever, to be attended with abscesses of this kind. Where an affection of the liver has preceded or accompanied the disease of the lungs, such dispositions are not uncommon, and the event is such as we have described.

Some authors have contended that all fistulæ are critical, and we have sometimes inclined to that opinion; yet, as they may be sometimes safely cured, and the disease is inconvenient and distressing, if not acutely painful, should there be no other apparent disease, the operation may be attempted. If not advisable, country air, milk diet, a mildly tonic course of medicines, with gentle ecoprotics, will often relieve; and nature will sometimes complete the cure, or so far relieve the complaint as to produce no great inconvenience. See St. Andre on Fistula in Ano.

Dr. Monro's instruction we shall add: "Wherever the opening of the fistula is, if it hath any turnings where it reaches the gut, divide them, and make them straight, avoiding the sphincter. After this I attempt to promote incarnation, which might lessen the cavity, and by degrees fill it up, by injecting balsamic softening medicines; though sometimes a patient of a good habit may be cured by applying a poultice of bread and milk, and a digestive. If this fail, I endeavour to render the parts entirely callous and insensible, by injecting a mixture of lime water and brandy, with a little honey of roses, increasing the brandy and diminishing the rest, as the

parts lose their sensibility, until at length I inject pure alcohol, which renders them quite insensible."

When the operation is performed, a probe pointed bistoury is to be passed into the fistula, and the finger into the rectum, to meet it. If the fistula is incomplete, the probe is sometimes passed through the gut, at its upper part, to render it complete; but this, we think, should be avoided. The sharp pointed bistoury is then passed along the other, and the sinus divided. In general, however, the probe is passed through the upper aperture, and bent down by the finger, when the sinus is cut through by the common scalpel. If the sinus goes beyond the reach of the finger, it should be divided only so far as the latter can extend; for beyond it the knife must not be trusted. As the external opening is usually on the outside of the rectum, the sphincter is commonly divided; but this occasions no inconvenience.

When the patient dreads the knife, it has been usual, in the complete fistula, to pass a silver or a leaden wire through the sinus, and to bend it from the upper orifice till it is again brought to the outside. The compression by this means destroys the life of the part; but the pain and irritation are too great to render it an eligible method.

It is styled an *occult fistula* when there is no external opening; and it is then difficult to determine whether the disease be really fistulous near the anus, or whether there be an abscess in the superior part of the intestine. The occult fistula is distinguished by a hardness, a painful swelling, and discoloration near the verge of the anus; while its existence is ascertained by matter being found mixed with the fæces, or following them. In the disease which is our present object, the matter more frequently follows the fæculent discharge. An opening is to be made in this case at the discoloured part, and the disease reduced to a complete fistula.

The disease is sometimes so violent and obstinate, that the parts in the vicinity, and sometimes the rectum itself, are separated from the organs around. Various methods of peculiar severity have been adopted on this occasion. It is, however, sufficient to lay a detached portion of the gut open on the side most affected, as in common fistulæ; and sometimes another portion on the opposite side. If the bones are sound, these operations will usually succeed.

When the matter insinuates itself into the perinæum, or down the hip, the sinuses should be laid completely open. When the matter has been long confined, the parts become hard and apparently scirrhus. In this case the sinus must not only be laid open, but the scirrhosities removed by the knife. It has been common to apply caustics for the latter purpose; but this mode of relief is tedious, and much more severe than the knife.

When the operation is finished, it has been the general practice to stuff the cavities with lint; but this occasions great irritation, and often induces diarrhœa. After cleaning the wound, pledgets are to be gently introduced, so as to cause no uneasiness. The sore, however, often assumes an unhealthy appearance, and the discharge is thin. Though this may arise from the sinus not being completely opened, it is more commonly owing to the weak state of the constitution. Bark, wine, and cold bathing, country air, and milk diet, have been recommended. Balsam of Peru and of capivi, turpentine, and other stimulating applications, have been

used often with little success. Unfortunately, when the wound *has* healed, worse symptoms have come on. *Patients* are, however, often *impatient*, and the surgeon must cure the wound which he has made, if he wishes to preserve his credit. It is melancholy to reflect, that we cannot always, at the same time, do our duty, and satisfy those under our care. We have sometimes succeeded in inducing patients to "bear the ills they have," rather than "fly to others that they know not of," and our best success has been obtained—by delay.

D. Mudge's "experienced and successful method of treating fistula in ano" consists in employing a speculum to dilate the rectum, and bring the parts more completely within the view. The callous edges of the wound are touched with butter of antimony; and when the surface appears preternaturally smooth, the precipitate ointment is applied.

See Heister's *Surgery*; Le Dran's *Operations*; Sharp's *Operations*; Pott's *Treatise on Fistulas*; Bell's *Surgery*, vol. ii. p. 282; Kirkland's *Medical Surgery*, vol. i. p. 201, 235; London *Medical Journal*, vol. v. p. 392; White's *Surgery*, p. 386.

FISTU'LA IN THE EPIDI'DYMIIS. In the London *Medical Observations and Inquiries*, vol. ii. p. 273, is an instance of a fistula in this part being cured. A man of thirty-five years of age hurt his testicles by a fall; a suppuration followed, and the matter was discharged externally. When the swelling was reduced by means of an emollient cataplasm, a fistula was discovered in each epididymis: a probe director was then introduced into the left sinus, which was cut open its whole length; after which all the indurated parts and the diseased skin were dissected; the same was done on both sides, and a part of the epididymis on the right side was cut away. The dressings, as in common wounds, finished the cure; and the functions of the testes were afterwards said to be fully executed.

FISTU'LA LACHRYMA' LIS, (see *ÆGYLOPS*.) is a disorder of the canals leading from the eye to the nose, which obstructs the natural passage of the tears, so that they trickle down the cheeks. In its first and mildest stage, an inflammation on the part is alone observed: in the next, matter is discharged from the puncta lachrymalia, which flows with the tears; the matter may proceed from an orifice through the skin, between the nose and the angle of the eye. The last and worst degree is, when the matter of the abscess has corroded the subjacent bone.

If the skin between the angle of the eye and the nose is not perforated, it is called *imperfect*; if corroded, a *perfect*; and if the subjacent bones are affected, a *compound, fistula lachrymalis*.

Other disorders near the seat of the fistula lachrymalis are confounded with it; but properly this kind of fistula is an erosion of the ducts of the lachrymal sac; in consequence of which, pus flows from them into the great angle of the eye; when the clear lachrymal fluid alone flows out, the disorder is an *EPIPHORA*, q. v. The matter of a proper fistula generally flows through the upper puncta, but sometimes through the lower only, or in a few instances through both.

The symptoms are, frequent dropping of tears, and of purulent matter, especially in the morning, without any manifest external inflammation. By pressing with the finger upon the lachrymal sac, a discharge of pus

follows through the puncta lachrymalia; and if this pus be offensive to the smell, or of a green or blackish colour, though not offensive, the adjacent bones are generally carious. When the matter is of a bad smell or colour, the probe will readily determine the state of the bone; for sometimes it is not injured, notwithstanding the attendance of the usual signs; and it is sometimes carious, when the pus is laudable. If, however, the discharge continues to be faulty, a caries will, for the most part, be formed in the lachrymal bone, the os planum, or in the jaw bone. If the nasal duct is obstructed, it is known by injecting some fluid into it, when, instead of passing into the nose, it returns by the puncta lachrymalia: if there is an encysted tumour, the exterior parts swell, and the tumour will not yield to the pressure of the finger, though there is no inflammation. When it does yield, there is a lachrymal hernia. Instances have occurred of a fistula lachrymalis not discharging pus with the tears, but alone when the patient was asleep; and this hath happened when the adjacent bones have been carious.

If the complaint is recent, the habit of body not remarkably diseased, the external skin not corroded, the nasal duct unobstructed, the matter of a good colour and consistence, incision and the cautery are unnecessary; for compression and mild astringent collyriums will be sufficient: the matter should be occasionally pressed out with the finger, to prevent its acquiring an acrimony. But if the duct into the nose is stopped, nothing will succeed but the operation. In performing it, the loose skin of the under eye lid must be pressed upon the globe of the eye, and a passage into the lachrymal groove cut: this is known by the crackling of the os unguis under the pressure of the knife; a probe must then be introduced to perforate into the nose. It is necessary to guard against cutting on the upper part of the maxillary bone, which will be discovered from the resistance. In that case the incision must be made further back. If, in perforating the os unguis, you press upon it too forwards, you will be obstructed by a part of the maxilla superior, which forms a portion of the canal in which the sac is lodged; if you press inwards, there will be danger of injuring the os, or septum nasi, or the os ethmoides: but if the instrument is passed backwards and downwards towards the uvula, no obstruction will occur.

For compressing instruments with which to cure the slighter cases, see Sharp's Operations, and Gooch's Cases. On the Fistula Lachrymalis, see Sharp's Operations; Le Dran's Operations; Edinburgh Medical Essays, vols. ii. and iii; Pott's Treatise on the Fistula Lachrymalis; St. Yves on Disorders of the Eyes; Heister's Surgery; Bell's Surgery, vol. iii. p. 469; Kirkland's Medical Surgery, vol. ii. p. 134; London Medical Journal, vol. i. p. 62, vol. ii. p. 77, 245; Nosology of the Eyes, p. 77, 83; White's Surgery, p. 256.

FISTULA IN PERINÆO consists in an opening in the skin, corresponding with one in the urethra. It sometimes happens that one opening from the side of the urethra corresponds with several through the skin; but it rarely happens that there is more than one opening from the urethra.

After lithotomy, a puncture of the perinæum, an abscess in the same part near the urethra, a scirrhus in

the prostate, &c. a fistula is sometimes formed, through which the urine partly passes, while the rest is conveyed through the natural passage.

A fistula proceeding from the urethra runs in various directions before it reaches the external opening of the skin; so that when the latter is near the anus, it may be taken for a fistula in that part; but the discharge of urine through the fistula at once distinguishes its nature.

Besides the callosities on the external orifice of these fistulas, there are sometimes calculous concretions lodged in their cavities; indeed, so various are the circumstances attending different cases of this kind, that only general rules can be laid down for their treatment.

In general the outward opening must be enlarged by cutting away the callous lips, or destroying them by caustic; but it sometimes happens that the same end may be attained by distending the urethra with a bougie. Le Dran observes, that though there are several fistulous orifices, and several callosities in the perinæum, when the water passes off in a small stream through the natural passage, the chief remedy will be the introduction of bougies; for as this canal is enlarged, the external orifices are diminished and healed, and the callosities consequently softened. Mr. Bell prefers the cure of this fistula by the introduction of a seton. See FISTULA. Le Dran's Operations. Bell's Surgery, vol. ii. p. 226. London Medical Journal, vol. i. p. 379. White's Surgery, p. 395.

On fistulas in general, see Celsus, Boerhaave's Aphorisms, and Pott's Treatise on Fistulas.

FISTULA'RIS. FISTULAR. In botany, those flowers are thus called which are compounded of many long hollow small florets, like pipes; and those plants are called fistulous whose stalks are hollow, like a pipe.

FISTULO'SUM FO'LIIUM. See FARCTUS.

FIXA'TIO. FIXATION. In chemistry it is the rendering any volatile substance fixed, so as not to fly off upon being exposed to an intense heat.

FL. LAP. The abbreviation of Car. Linnæi Flora Lapponica.

FLABELLIFO'RMIS, (from *flabellum*, a fan, and *forma*, likeness). In botany it means a leaf, shaped like a fan.

FLA'GELLUM. A LASH. In botany, a barren twig, a shoot like a thong.

FLA'MMULA. Formerly a skein of silk with which setons were made. The name also of several species of ranunculus, of the atragene and clematis.

FLA'MMULA JO'VIS, (from its burning acrimony). *Surrecta alba*. The UPRIGHT LADY'S BOWER, *clematis recta* Lin. Sp. Pl. 767. UPRIGHT TRAVELLER'S JOY. The recent leaves, and in a less degree the flowers, on being chewed, excite a burning heat of the tongue and fauces; and if retained long in the mouth, produce a blister; but by drying, this acrimony is considerably diminished. The root, seed, and bark, if rubbed with the fingers, strike the nostrils very quickly with a strong smell. This plant yields a very acrid water; and Stoerck has published several cases of its successful exhibition, particularly in inveterate headaches, pains in the bones, nodes, ulcers, and cutaneous affections from syphilis. He chiefly recommends an infusion of two or three drachms of the leaves in a pint of boiling water, of which four ounces are to be taken

three times a day, whilst the powdered leaves are employed as an escharotic. (See Stoerck de *Flammula Jovis*.) In this country it has been little employed, and with less success.

FLATULENTUS, and FLA'TUS FURIO'SUS. See AMBULO.

FLA'TUS. FLATULENCE. Vapours rarefied by the heat of the containing part. Distensions, uneasy sensations, and often a considerable degree of pain, are the consequence. The term is confined to wind in the stomach and intestines. In other cavities, it is called *tympbanites*. See APEPSIA, DIGESTIO, and HYSTERIA.

FLA'VII CLEME'NTIS MEDICAME'NTUM. The name of a medicine for the gout, described by Actuarius.

FLA'VUS CO'RTEX. YELLOW BARK. This bark, very lately introduced into practice, is supposed to be a species of cinchona, growing in the interior mountainous parts of America, described by Murray under the title of *cortex chinæ*, vel *chinchinæ regius*, seu *cortex chinæ flavus*. This bark, according to Murray, consists of flattish pieces of about the length of a finger, the breadth of the thumb, and a line in thickness. Its colour is yellowish, inclining to that of the red oxide of iron. It partakes more of the ferruginous colour on its external than on its internal surface, owing to the close adhesion of the epidermis to the bark. Both in its fracture and on its surface it appears fibrillous, breaking easily between the fingers, so that it may be rubbed into a yellow powder. In taste it is intensely bitter, with a slight degree of astringency. Its efficacy is considered as far superior in intermittent fevers to the bark commonly employed. Dr. Relph observes, that in colour it only approaches nearer to a yellow than any other species of Peruvian bark imported into this country, especially when reduced to powder; that it consists of flattish irregular pieces, of a cinnamon colour, inclining to red, having, in certain directions of the light, a peculiar sparkling appearance on the surface. The pieces are very generally divested of the cuticle, of a fibrous texture, dry, and rigid to the feel, easily rubbed to powder between the finger and the thumb; not remarkable for their specific gravity. They have little odour, but to the taste are intensely bitter, with a moderate share of astringency, and a flavour corresponding unequivocally to that of the cinchona officinalis. The external surface of this bark is somewhat of a deeper colour than the internal, and in some specimens it is as deep as that of the red bark. The pieces vary much in size; some are about two inches and a half in length, an inch in breadth, and the sixth of an inch in thickness; while others are still smaller; and some are to be found from twelve to eighteen inches in length, with the breadth and thickness in proportion. Pieces sometimes through the whole chest are nearly cylindrical, and as completely covered with an outer coat as the most perfect specimen of common bark. The epidermis of the large pieces of the yellow bark is of a reddish brown colour, rough, and of a somewhat spongy texture; but that of the smaller pieces is grey, harder, and much more compact.

Like the cortex Peruvianus, it yields its virtues to

water by infusion or decoction, to proof or rectified spirits, and extracts may be formed from either in the usual way. It is considered to possess the same virtues, but in a greater degree than either the common or red bark, consequently to be more efficacious in smaller doses. For the complaints to which it is adapted, see CORTEX PERUVIANUS: the dose of the powder is from ℥ss. to ℥ij.—of the extract half the quantity is sufficient. See Relph on the Yellow Bark.

FLE'MEN, (quasi FLEGMEN, from *flecto*, to *incline downwards*). A tumour about the ankles; or callous furrows in the hands or feet.

FLERE'SIN. See ARTHRITIS.

FLE'XOR, (from *flecto*, to *bend*). A name applied to several muscles, from their office of bending the parts to which they belong.

FLE'XOR BRE'VIS MI'NIMI DI'GITI MA'NUS, rises from the unciform process of the carpus, toward the annular ligament, and is inserted into the basis of the little finger.

FLE'XOR CA'PITIS. See RECTUS INTERNUS MAJOR.

FLE'XOR CARPI RADIA'LIS; *flexor carpi exterior*, and *bicornis*; rises from the anterior part of the inner condyle of the os humeri, passes toward the outside, and runs through the annular ligament, being partly inserted into the trapezium, and partly into the first metacarpal bone.

FLE'XOR CA'RPI ULNA'RIS, *flexor carpi interior*, rises from the inner condyle of the os humeri, and almost from the whole surface of the ulna, forming a tendon inserted into the os pisiforme.

FLE'XOR DI'GITI PA'RVI MI'NIMI. See ABDUCTOR MINIMI DIGITI MANUS.

FLE'XOR DIGITO'RUM ACCESSO'RIOUS. See FLEXOR LUNGUS PEDIS. Dr. Hunter calls it *accessorius*.

FLE'XOR DIGITO'RUM PE'DIS. See FLEXOR SUBLIMIS.

FLE'XOR SECU'NDI INTERNO'DII DIGITO'RUM PE'DIS. See FLEXOR SUBLIMIS.

FLE'XOR INTERNO'DII PRI'MI DIGITO'RUM. See LUMBRICALES. Dr. Hunter describes the lumbricales as productions of the flexors, and distinctly that called

FLE'XOR INTERNO'DII PRI'MI PO'LLICIS MA'NUS, rising from the annular ligament of the carpus, and inserted into the first bone of the thumb.

FLE'XOR INTERNO'DII PRI'MI et SECU'NDI PO'LLICIS. These muscles rise sharp and fleshy about the middle of the back part of the fibula; then, running into a tendon in passing over the joint, and through a channel in the inner part of the os calcis, are inserted into the upper end of the second bone of the great toe.

FLE'XOR INTERNO'DII SE'CU'NDI DIGITO'RUM MA'NUS, *flexor sublimis*, or *perforatus*, rises from the inner condyle of the os humeri, and from the fore part of the head of the ulna and radius; passes through the annular ligament, and spreads out into four tendons, which are inserted into the basis of the second phalanx: these are bound down by what is called an *annular ligament*, which is really a general sheath of the fingers, thicker at the joints than elsewhere. Brown calls this muscle *flexor secundus*.

FLE'XOR INTERNO'DII SECU'NDI PO'LLICIS MA'NUS, is made up of two portions, the anterior of which

is inserted into one sesamoid bone, the posterior into the other.

FLE'XOR INTERNO'DII TE'RTII DIGITO'RUM MA'NUS, by Dr. Hunter called *perforans manus*; *profundus manus*; rises from the inner condyle of the os humeri, from the external part of the ulna about its middle, and from the interosseous ligament; runs between the perforatus, and forms four tendons, which pass through as many slits in the perforatus, to be inserted into the basis of the last phalanx.

FLE'XOR INTERNO'DII TE'RTII PO'LLICIS, VEL LONGI'S-SIMUS PO'LLICIS MA'NUS, hath sometimes a twofold beginning; one from the internal substance of the os humeri, between the perforatus and perforans, but this head is occasionally wanting; or springs from the upper and fore part of the ulna: the second head rises on the radius, passes over the articulation of the carpus, and is inserted in the upper part of the third bone of the thumb.

FLE'XOR LO'NGUS, OF PE'RFORANS PE'DIS, called also *accessorius*, rises from the posterior part of the tibia, just below the poplitæus, and from the interosseous ligament; goes on the inside of the astragalus and os calcis (from whose internal part a short head arises, called *accessorius*), and passing through the slit of the perforatus, its four tendons are inserted into the basis of the last bones of the toes. This muscle receives some fibres from the flexor pollicis longus.

FLE'XOR PE'RFORANS MA'NUS. See FLEXOR INTERNO-DII TERTII DIGITORUM MANUS.

FLE'XOR PO'LLICIS BRE'VIS, is short, thick, and fleshy, seemingly divided into two muscles, by the tendon of the flexor pollicis longus passing over it. It rises from the upper part of the os cuneiforme medium, and, running over the termination of the musculus peronæus primus, is implanted into the ossa sesamoidea of the great toe, which are likewise tied to the superior part of the second bone of that toe.

FLE'XOR PO'LLICIS LO'NGUS MA'NUS, rises from the fore part of the radius, and commonly receives one slip from the coronoid process of the ulna; forming a tendon which passes deep under the annular ligament, runs between the two sesamoid bones, over the first and second bone, to be inserted into the basis of the third.

FLE'XOR PO'LLICIS LO'NGUS PE'DIS, rises from the posterior part of the fibula; passes in a groove between the astragalus and os calcis; is covered by the abductor pollicis, and goes between the sesamoid bones, where it meets with an annular ligament, to be inserted into the last bone of the great toe. It gives some fibres to the perforans pedis.

FLE'XOR PO'LLICIS O'SSIS PRI'MI et SECU'NDI, is a large disgregated muscle, arising from the ligamentum transversale carpi, the bones of the carpus at the basis of the mons lunæ, and the os metacarpi of the middle finger, whence it passes to its insertion into the first and second bones of the thumb. In its tendon, near the insertion into the first bone of the thumb, are placed two sesamoid bones. Its actions are various, as are the directions of the muscular fibres.

FLE'XOR SUBLI'MIS, OF PERFORATUS PE'DIS, called by Winslow, *flexor digitorum brevis*, and by Brown, *flexor secundi internodii digitorum*; rises from the lower and inner part of the os calcis; is divided into four ten-

dons under the sole of the foot, which are inserted into the bones of the second phalanx.

FLEXUO'SUS, (from *flecto*, to bend). This applies to the stalk in botany, and means having many turnings, bent differently at every joint.

FLORA'LIS, (from *flos*, a flower,) belonging to a flower; the leaves which immediately attend the flower.

FLO'RES. (See FLOS.) FLOWERS. In chemistry, they are the most subtle parts of bodies, separated from the more gross, by sublimation in a dry form, and found under the respective names of the materials used, as *flores benzoini antimonii*, &c. Mace is sometimes, called the *flowers* of nutmeg. In pharmacy, they are directed to be gathered when moderately expanded, on a clear dry day before noon. Red roses are taken before they open, and the white heels are cut off and thrown away. Those flowers which are gathered for keeping should be dried in the shade, but as quickly as possible; in some instances, the place may be warmed by a fire, though the sun should not shine upon them. When the flowers are dried, they must be kept close and dry. With their scent and colour they lose their virtues. The medical virtues of different flowers reside in different parts; e. g. saffron is a production which rises from the style of the flower; the active part of camomile flowers is in the yellow disk; in roses, lilies, and several others, the virtues are in the petals; and the flavour admired in rosemary flowers is chiefly in the cups.

FLO'RES ANTIMO'NII. See ANTIMONIUM.

FLOS, (from $\phi\lambda\omicron\varsigma$, *quia emicat ut flamma*; or from *flando*, *quia spirat odorem*: some authors derive it from $\chi\lambda\omicron\omicron\varsigma$, green). A flower is that part of a plant in which the parts of generation of either sex reside. In some flowers are the parts proper to one sex only; in others both sexes are included in the same flower. A flower, when complete, consists of a calyx, corolla, stamen, and pistil; but the essential parts are the anthera at the top of the stamen, and the stigma: these are sufficient to constitute a flower.

Tournefort's system, which alone could be the rival of the Linnæan, depended on the form of the flowers: as it is not yet wholly disused in France, though superseded rather by Jussieu's natural arrangement than the Linnæan system, we shall shortly give its outline.

The vegetable kingdom is divided into *herbs* and *trees*. *Herbs* are such as have flowers with petals or without them. The petalodes are simple or compound. The simple-leaved flowers are divided into monopetalous and polypetalous; the former into regular and irregular; the regular flowers into the *campaniformes* and *infundibuliformes*; the irregular into *labiati* and *anomali*. The *polypetali regulares* are the *cruciformes*, *rosacei*, *umbellati*, *caryophyllæi* and *liliacei*. The irregulars are the *papilionacei* and *anomali*. The compound petalodes are the *flosculosi*, the *semiflosculosi*, and the *radiati*. The apetalis are either those without leaves and without a flower, or without flower or fruit.

The flowers of *trees* are similarly divided. The apetalous ones are the *apetalis* and *amentacei*; the petalodes monopetalis contain only the *monopetalis*; the others are the *rosacei* and *papilionacei*. According to Linnæus, the calyx is the expansion of the epidermis, the corolla or flower of the liber or inner bark.

FLOS ABO'RTIENS. ABORTIVE FLOWER, producing no fruit.

FLOS AMENTACEUS. See AMENTUM.

FLOS APE'TALUS; is without a corolla; often called stamincous, incomplete, imperfect. The parts of generation are covered only by the calyx.

FLOS CAMPANIFO'RMIS, shaped like a bell. Those whose edges spread wide, are termed open bell shaped flowers; those less spread, tubulous bell shaped flowers.

FLOS CARYOPHYLLE'US, resembling a single carnation, having five regular petals, ending at the bottom in a long narrow claw.

FLOS COMPO'SITUS; a species of aggregate flower, containing several florets, inclosed in a common perianth, and on a common receptacle, with the anthers connected in a cylinder.

FLOS CRUCIFO'RMIS, is composed of four equal petals, placed in the form of a cross. Of this sort are the cabbage, the wall flower, and mustard.

FLOS FEMI'NEUS. FEMALE FLOWER, which has pistils or stigmas, without stamens, or at least antheræ.

FLOS FLOSCULO'SUS. A FLOSCULOUS FLOWER. By Linnæus called *tubulosus*, a *tubulous compound flower*, composed wholly of tubulous florets, exemplified in tansy, and the camomile flowers.

FLOS INFUNDIBULIFO'RMIS. A funnel shaped flower, as the primrose, &c.

FLOS LABIA'TUS. LIP SHAPED FLOWER. A monopetalous corolla, with a narrow tubular basis, expanding at the top in one entire, or in two lips: Linnæus uses the term ringens, including under it both labiated and peronate flowers. This creates a confusion, which, according to Martin, would be removed, if we put labiate for an irregular monopetalous corolla with two lips, and appropriate the term ringens to such as have the lips gaping and open, peronate to such as have them closed. Sometimes the upper lip is wanting, and then the style and chives supply its place, as in the ground pine, bugula, &c. This is sometimes called an unlabiated flower. In some species, the upper lip is turned upwards, as in the ground ivy; but most commonly the upper lip is convex above, or turns the hollow part down to the under, representing an helmet, whence they are called *galeate*, *cucullate*, and *galericulate*.

FLOS LILIA'CEUS. A LILY SHAPED FLOWER, is generally composed of six petals, which resemble those of the lily, the tulip, and the asphodel: and is a natural order of Murray.

FLOS MONOPE'TALUS. A flower composed of one leaf; or whose leaves are joined at the bottom, so as to fall off entire.

FLOS MA'SCULUS. MALE FLOWER; bearing stamina only, without pistils; or at least wanting the stigma.

FLOS MONOPE'TALUS ANOMALUS. An irregular flower, consisting of one leaf.

FLOS PAPILIONA'CEUS, (from *papilio*, a *butterfly*). THE PAPILIONACEOUS, OR BUTTER FLY SHAPED FLOWER, is irregular and usually four petalled. The lower petal is shaped like a boat, and is called *carina* or *keel*; the upper, which spreads and rises upwards, is called *vexillum*, *standard* or *banner*; the two side ones are separated by the keel, and are called *alæ*, the *wings*; the keel is sometimes split, and then this corolla is

properly five petalled. These flowers are called PEA BLOSSOMED, because the pea is the most common example.

FLOS PERSONA'TUS, a MASKED FLOWER, is an irregular monopetalous flower, in which the pistil becomes a capsule entirely distinct from the calyx: it has a similar appearance with the labiate flower; but does not ill represent a mask, the snout of some animals, or the beaks of fowls.

FLOS PETALO'DES, a PETALOUS FLOWER, has organs of generation surrounded with petals.

FLOS POLYPE'TALUS, a POLYPETALOUS FLOWER, is composed of several petals. When these agree in figure and position, it is called *regular polypetalous*; but when they do not agree, *irregular polypetalous*.

FLOS PYRAMIDA'LIS FARNE'SIANUS. See BATTATAS CANADENSIS.

FLOS RADIA'TUS, a RADIATED FLOWER, consists of two parts, viz. the disk and the rays, which are several semiflorets set round the disk in the form of a star: these are called *radiated discous flowers*; but those which have no rays are called *naked discous flowers*.

FLOS ROSA'CEUS, ROSE SHAPED FLOWERS, consist of four or more regular petals inserted into the receptacle by a short broad claw, as in the wild rose.

FLOS ROTA'TUS, is a flower in the form of a wheel; wheel shaped corolla; monopetalous; spreading flat, without any tube; such as that of borragé.

FLOS SANGUI'NEUS MONA'RDI. See NASTURTIUM INDICUM.

FLOS SCORPIOIDES. Those flowers are ranged on one side of the pedicle, which twists at the top, in the form of a scorpion's tail. Of this sort is the heliotropium.

FLOS SEMIFLOCCULO'SUS, a SEMIFLOCCULOUS FLOWER, is composed of several semiflorets, included in one common calyx.

FLOS SO'LIS PYRAMIDA'LIS. See BATTATAS HISPANICA.

FLOS SPICA'TUS, SPIKED FLOWER, is one whose flowers are set thick on the pedicle, so as to form an acute cone.

FLOS STAMINEUS, a STAMINEOUS FLOWER, is composed of many chives included in a calyx, having no petals. Of this sort is the bistort, &c.

FLOS STE'RILIS. BARREN FLOWERS. These have no embryo adhering to them, and are called *male flowers*.

FLOS TE'RRÆ. See CÆLI FLOS.

FLOS TUBULO'SUS. See FLOS FLOSCULOSUS.

FLOS VENTRICULA'TUS. WHORLE SHAPED FLOWER. These grow closely united, surrounding the stalk at the joints.

FLOS UMBELLA'TUS. AN UMBELLATED FLOWER. When the extremity of the stalk or branch is divided into several pedicles, or rays, beginning from the same point, and opening in such a manner as to form a kind of inverted cone, like an umbrella, it has this appellation. When the pedicles, into which the stalk is divided, are subdivided into others of the same form upon which the flowers are disposed, the first order is called *rays*, the second *pedicles*. When it consists of pedicles only it is called a *single*, when composed both of rays and pedicles a *compound umbel*.

FLOS URCEOLA'TUS. PITCHER SHAPED FLOWER, bellying out like a pitcher; applied to the calyx, corolla,

and nectary. Of this sort are the arbutus and whortleberry flowers.

FLO'SCULUS, (a dim. of *flos*, a flower). A FLORET, or LITTLE FLOWER, one of the distinct florets which compose an aggregate flower.

FLUIDA. The fluids of the body have been classed according to their form, or their qualities. In the former view, they may be arranged under the heads of *gaseous*, *watery*, *oily*, *glairy*, or *mucous*. The *gaseous* fluids are the insensible perspiration from the surface, and the lungs; some gas combined loosely with the blood; the contents of the pericardium; of the ventricles of the brain; of the duplicature of the peritonæum, perhaps of the sheaths of the nerves; more certainly of the stomach and intestines. The *watery* fluids are, the circulating, the secreted, and the absorbed fluids: the *oily*, the contents of the adipose membrane, the bile, and cerumen; the *glairy*, those contained in the cavities of the joints; the *mucous*, those which line surfaces contiguous to each other, generally such as admit of occasional dilatation for the passage of any body, as the throat, the vagina, &c.; often those whose accretion this fluid is designed to prevent, as the eye lids, the prepuce, &c.

Dr. Hooper divides the fluids from their qualities into the *crude*, more properly the *alimentary*, as the chyme or chyle; the *sanguineous*, as the fluids of the heart, arteries, and veins; the *lymphatic*, or the contents of the lymphatic system; to which he adds the *nutritious gelatine*; the *secreted* and the *excrementitious*.

The secreted fluids may be again divided according to their form, as stated above; but the varieties are numerous, and the shades of distinction often minute. Thus milk unites the watery and the oily; the semen approaches an albumen, and the liquor of the prostate remains to be more accurately examined. The diseases of the fluids are numerous, but must be the subject of a separate consideration. See MORBI FLUIDORUM.

FLU'OR, also **FLUS**, (from *fluo*, to flow). This word, when used adjectively, is applied to signify the habitual fluidity of any substance, implying that it cannot be rendered solid; e. g. a volatile alkali treated with quicklime is always liquid, and cannot be made to concreate or crystallize, so is called *fluor volatile alkali*, to distinguish it from the common carbonated ammonia.

When the word fluor is used substantively, it signifies a fusible mineral, or one which facilitates fusion. Of this kind are many spars, which are called *fluors*; and by the word fluor, spar is generally understood. Spar appears like crystal; but less bright, colourless, and pellucid; it commonly rises in triangular points, and is calcareous: it is the same with stalactite.

The spar fluor is a fluete of lime; or calcareous earth with the fluoric acid. Of this spar the ornamental vases and columns from Derbyshire, are made; but it is never employed in medicine.

FLU'OR A'LBUS. The WHITE FLUX, the WHITES, *eluvies*, *cachexia uterina*, *leucorrhœa*, *leucorrhœis*, &c. is a flow of matter from the vagina, of different colours and consistencies, but generally of a pale or whitish colour. Astruc distinguishes, by an useless refinement, this discharge into the lymphatic, semilacteous, and lacteous. In Dr. Cullen's Nosology it is the menorrhagia

alba; the fifth variety of his menorrhagia. He defines it "a serous menorrhagy, without any local injury in women not pregnant." He places it under this head, because the leucorrhœa is usually joined with menorrhagia, or soon follows it; and because it is highly probable that the serum flows from the vessels which supply the menses. The causes of leucorrhœa also are often the same as those of menorrhagia.

The seat of this disorder seems to be in the uterus, near the os internum, though principally in the vagina. Astruc thinks its seat to be in the glands, situated on the third or internal tunic of the uterus, and that they are vesicular bodies about the fundus uteri; these glands he calls *colatoria lactea*, and adds that this disease consists in a preternatural discharge from them. The uterine exhaling vessels, according to Hoffman, "become blood vessels at the menstrual period, and when emptied they contract to their former dimension and tone; but if by immoderate evacuations, or other causes of debility, their power is weakened, they separate the serous part of the blood, which, by stagnation, or from a particular state of the body, acquires various degrees of acrimony and consistence." As pregnant women are liable to this complaint, it does not appear that in them the discharge proceeds from the uterus, except from about the os internum; for the spongy chorion firmly adheres to its inner surface in almost every part. Some women have, indeed, a return of the menses in every month of pregnancy, which, though deficient both in quantity and quality, confirms Hoffman's opinion, as well as that the vagina may be a principal seat of the discharge.

Women who abound with serum, with lax fibres, or at the decline of life, and girls at the approach of the menses, are most subject to this disorder; though it sometimes occurs from infancy to old age. Hoffman observes, that women who are subject to a mucous defluxion at the nose are, on a suppression of the menses, affected with a fluor albus.

That the immediate cause of a fluor albus is debility of the vessels from which the menstrual discharges flow, or a retarded circulation of the blood through them, appears from some women having always a leucorrhœa whenever their menses are detained. In languid habits the disease returns periodically, instead of the proper menstrual evacuation, until the patient's constitution is sufficiently invigorated; and in many instances it is manifest only during the absence of the menses.

The more remote causes are, cold moist air, a sedentary life, poor diet, excessive menstrual discharges, abortions, violent extraction of the placenta; indeed, every circumstance which weakens the constitution in general, or these vessels in particular.

From Hippocrates' description, it appears to have a great affinity to a cachexy. He says, "that the matter discharged resembles the white urine of an ass; white swellings appear in the patient's face, the part below the eyes swells, the eyes are disordered, and appear as if the patient was dropsical; the colour of the skin is whitish, and the lower part of the belly tumid; in the legs appear tumours so lax and so soft, as to retain the impressions of the finger; a biting pain is perceived in the stomach, and a sensation of an acid water lodged

in it, either when the patient is fasting or happens to vomit; when she goes up a steep place, she is seized with short breathing; her legs are cold, her knees feeble, her uterus preternaturally opened, with a sense of weight at its mouth. This discharge is sometimes daily, and occasionally it appears two or three times in a month, and continues, each time, only a few days; the humour is serous and limpid in some, and in others more viscid: sometimes it is acrid, and occasions an itching, pricking, or even an excoriation; in its greater degrees of virulence, it appears of different shades, from the slightest yellow to a green or even a blackish green colour, and it is then more or less fetid. When the case is mild, it is often not regarded; but when more violent, a cachexy is the consequence. There is in that case a pain and sense of weight in the loins, turbid urine, longings and loathings, indigestion, swelling of the face in the night and of the feet in the day, palpitation of the heart, fainting, symptoms ending fatally in dropsy, or a consumption."

This disorder should be distinguished from a cachexy, a gonorrhœa, pale and ill coloured menses, and from ulceration, abscesses, and cancers in the parts of generation.

Leucorrhœa is often a symptom of cachexy, and the treatment is the same, so that distinction is not necessary. It is frequently mistaken for gonorrhœa; and in turn the latter is styled the whites. Leucorrhœa, when violent, is attended with a discharge as thin, as discoloured, and as acrid as gonorrhœa; and the character of the woman or her husband will, at times, be the only means of distinguishing the complaint. This similarity is, however, advantageous in another view, as it enables the practitioner to preserve the peace of a family, by giving a safer name to the effects of imprudence. If a woman is regular, it will be found that, during the discharge of the menses, the whites disappear; but the matter of a gonorrhœa is found combined with the blood; and except in very old women, whom we cannot suspect of gonorrhœa, the discharge is seldom so acrid as to occasion pain in making water.

Ulceration and abscesses in these parts have been usually preceded by inflammation, or may be traced to some violence; and the discharge of cancers is attended by the violent lancinating pains at the bottom of the belly. The discharge from cancers also, we believe, is the only fluid from those organs, which discolours bright silver.

If this disorder is moderate, it is supported a long time without much inconvenience; but if considerable, it soon spoils the beauty, weakens the digestive powers and the whole system, occasions sterility, and more frequently a disposition to miscarry. If the flux is unseasonably checked, the belly is said to swell, a hectic fever to come on, and a train of the most disagreeable symptoms to follow. We suspect, however, that to check it quickly is no easy task.

The indications of cure are, to promote digestion, increase the strength, and restrain the preternatural discharge. The diet should be light, cordial, and nourishing; isinglass dissolved in milk is useful, with moderate quantities of red port.

Leucorrhœa is with great difficulty removed. If it proceeds from partial debility of the vessels of the

womb and vagina, from frequent births or miscarriages, remedies can scarcely be brought to act on such remote organs; and to remove partial debility by general remedies is a tedious, and often an unsuccessful, task.

Avoiding irritation of body and mind is highly necessary; and it is equally so to guard against topical irritation. The bowels must therefore be kept free, and every excitement of the uterine system avoided. Moderate exercise in cool air, cool rooms, and light clothing, food nourishing, but not highly spiced, or flatulent, are useful. The most scrupulous cleanliness is essential; and injections of milk and water, or green tea, should be frequently thrown up, cold.

Tonic medicines are principally employed; and the chief of these is cold bathing. The chalybeate mineral waters are remedies of considerable importance, among which the Cheltenham and Tunbridge springs are most useful. The bark is often employed, and is frequently salutary; but the more powerful astringents are said by Hoffman to be injurious. The humoral pathologists, in almost every disease, suspected acrimony; and this idea has led to the use of absorbents and of alteratives and mercurials, in leucorrhœa. The former are at least innocent; and as, in such circumstances, acids often abound in the stomach, they may be useful. Mercurials are, we believe, injurious, if we proceed beyond the slightest doses, to give a general tone to the arterial system. For the same purpose chalybeates are generally and freely employed. They have been used also for injections; and smiths' forge water has been recommended. This fluid, however, soils the linen, and as a powerful astringent may be injurious.

The alteratives employed have been the Lisbon diet drink, antimonials, and sarsaparilla. They have been supposed useful when the discharge is highly acrimonious; but we have seldom employed them, and scarcely in any instance found them effectual. The disease is peculiarly obstinate, and to relieve it our almost only chance.

See Cullen's First Lines, vol. iii. p. 24, 31. Hamilton's Midwifery, edit. 2, p. 119, 137, 140. Hoffman's Dissertation on the Fluor Albus. Leake's Medical Instructions, edit. 5.

FLUS, (from *fluo*, to flow). See FLUOR.

FLUVIA'TILIS, (from *fluvius*, a river). Belonging to a river.

FLUX, synonymous often with fusion; and frequently implying the substance by which fusion is promoted. It has various names from its appearance or nature, as black or white flux, crude flux, &c. In general it consists of a mixture of nitre and tartar.

FLUXIO. See CATARRHUS.

FLUXUS, (from *fluo*, to flow). A FLUX. Sometimes it signifies a defluxion, and in this sense it is synonymous with catarrh. Sometimes it is used in a more limited sense, as fluxus ventris, a continued evacuation of thin fæces, without either tenesmus or lientery; or a fluxus hepaticus, when the excrements are like water in which flesh hath been washed. Hippocrates uses the word $\rho\omicron\sigma$, fluxus, in his work de Natura Muliebli, of which there are the fluor albus, and fluor ruber, i. e. menses. Fluxus $\rho\upsilon\sigma\iota\varsigma$ means a loss of the hair, in A. Trallian. (lib. i. cap. 2.) In Cullen's Næsolology, it is synonymous with Apocnoses.

FOCA'RIOUS, (from *foveo, to burn*). Bread boiled on the hearth or gridiron.

FO'CILE MA'JUS et MI'NUS. ARABIC. Barbarous appellations of the ulna and radius in the arm; the tibia and fibula in the leg.

FO'CUS (from *foveo, to burn*). The burning point of the speculum, or rather the point at which all the rays of light converge when bent towards the perpendicular by a convex lens. Focus morbi is the supposed principal residence of the disease, from whence it communicates its noxious influence. Some ancient anatomists gave this name to the first lobe of the liver. See AURIGA.

FODI'NA, (from *fodio, to dig*). See LABYRINTHUS.

FŒ'DULA, (from *fœdus, foul*; from its stinking smell, when rotten). A species of fungus.

FŒNI'CVLI, vel FŒNICULA'TUM LI'GNUM. See SASSAFRAS.

FŒNI'CVLUM; a diminutive of *fœnum, hay*; because when dried, it is preserved; or quasi *fœnum oculorum*, the hay or herb good for the sight. FENNEL. Wine impregnated with it is called *marathrites*.

FŒNI'CVLUM VULGA'RE, *fœniculum* Germanicum, *marathrum*, COMMON FINCLE, or FENNEL; *Anethum fœniculum* Lin. Sp. Pl. 377.

This plant is so common that a description is unnecessary: its seeds are small, and of a blackish brown. The plant is perennial, native in the southern parts of Europe, but thrives in our gardens; supposed to be the *marathron* of the Greeks, highly esteemed among them for promoting the secretion of milk. The experience of Bergius seems to confirm this opinion.

The seeds are more warm and pungent, but not so pleasing, as those of the sweet kind. They are stomachic and carminative, commended against nausea and loathing; and if eaten in the morning fasting, supposed to help the sight. Dill, anise, and carraway, are, however, allowed to be superior in these respects.

The leaves have the same flavour with the seeds, and smell stronger, but to the taste are weaker and less agreeable. They impregnate water sufficiently with their virtues by distillation, and by the same process afford a considerable quantity of essential oil. Rectified spirit of wine is rendered agreeably aromatic by them, and the extract retains the whole strength after evaporation.

The roots, taken up in spring, have a pleasant sweet taste, are slightly aromatic, and are ranked amongst the aperient roots.

FŒNI'CVLUM DULCE. SWEET FENNEL. This variety of the anethum fœniculum; var. *a*, is annual, a native of warm climes, and cultivated in gardens. The seeds are larger, paler, and sweeter than those of the former sort; contain a gross oil, easily obtained by pressure, and have been esteemed pectoral and diuretic: when freed from the essential oil, they are perfectly insipid. The London college directs us to distil a simple water from the seeds, and from a pound to draw off a gallon; which is said to be diuretic and carminative. See Lewis's *Materia Med.* Neumann's *Chem.* Works.

FŒNI'CVLUM ALPI'NUM. See MEUM.

FŒNI'CVLUM ANNUM. See AMMI VERUM.

FŒNI'CVLUM ERRATICUM. See SAXIFRAGA ANGLICA.

FŒNI'CVLUM MARI'NUM MA'JUS et MINUS. See CRITHMUM.

FŒNI'CVLUM ORIENTA'LE. See CUMINUM.

FŒNI'CVLUM PORCI'NUM. See PEUCEDANUM.

FŒNI'CVLUM SINE'NSE. See ANISUM INDICUM.

FŒNI'CVLUM SYLVE'STRE. See MEUM LATIFOLIUM ADULTERINUM.

FŒNI'CVLUM TORTUOSUM. See SESELI MASSILIENSE.

FŒ'NUM CAMELO'RUM. See JUNCUS ODORATUS.

FŒ'NUM GRÆ'CUM, (from *fœnum, hay*, and *Græcus, Greece*; because it grew there in the meadows, like hay). FENUGREEK; *buceras*, because the fruit is corniculated; and *ægoceras*, because the pods were supposed to resemble the horns of a goat, *trigonella fœnum græcum* Lin. Sp. Pl. 1095. It is a plant with serrated, roundish leaves, whitish papilionaceous flowers, followed by long, slender, crooked, flattish pods, containing yellowish rhomboidal seeds, furrowed from one angle to the other; or, as Neumann observes, oblong, flattish, quadrangular, and roundish at one end. These seeds are sown annually in the south of Europe, from whence they are brought to us, and are the only parts of the plant employed; their prevailing principle is mucilage, and an ounce renders a pint of water very mucilaginous. They are chiefly used in emollient cataplasms and fomentations, and in emollient and carminative clysters. They are slightly bitter, and have a disagreeable smell. See Lewis's *Mat. Med.* and Neumann's *Chem. Works*.

FŒ'NUM GRÆ'CUM SYLVE'STRE. See GLAUX VULGARIS LEGUMINOSA.

FŒTA'BULUM, (from *fæto, to become putrid*), a FOUL ULCER; and an ABSCESS with a CYST. Severinus.

FŒ'TIDA TINCTU'RA. See ASAFŒTIDA.

FŒ'TUS, (from *fœo, to bring forth*). See VOSS. ETYMOLOG.) *Epicyma*, and *epigonion*. The young of all viviparous animals whilst in the womb, and of oviparous animals before they are hatched. (See CONCEPTIO). The name is transferred by botanists to the embryos of vegetables.

In the human fœtus are several peculiarities not to be found in the adult. 1. The *ductus, or canalis, arteriosus*. (See ARTERIOSUS DUCTUS). 2. The *arteries of the navel string*, which are continuations of the hypogastrics, after the birth, are shrivelled up, and form the *ligamenta umbilicalia inferiora*. 3. The *veins of the navel string*, which are formed by the union of all the venal branches in the placenta, and passing into the abdomen, become the *falciform ligament of the liver*: 4. The *ductus venosus*, q. v. 5. The *lungs*, which, before being inflated with air, are compact and heavy; but after one inspiration become light, and as it were spongy. When the lungs swim in water, it is supposed that the child has breathed; and the conclusion is drawn that it has been murdered. But the uninflated lungs become specifically lighter than water as soon as any degree of putrefaction comes on, which quickly happens after the death of the child; and where the utmost care hath been taken to preserve the child, it hath breathed once or twice, and then died; and on the other hand, they may sink, though the child has breathed, if tubercles have formed in them. (See *MEDICINA FORENSIS*.) 6. The *thymus gland* is very large in the fœtus, but lessens as years advance, 7: The *foramen ovale* in

the heart of a fœtus is generally closed in an adult. 8. *The circulation of the blood.* See CIRCULATIO.

These peculiarities of structure are connected with the state of the fœtus, while yet in utero, when it has the adventitious support of the mother, on whom its existence for a time depends. The uterine fœtus is inclosed in a bag, composed of different membranes, styled the *ovum*; but the whole, if we except the external membrane, the decidua, is a part of the fœtal system, and connected with its growth and existence.

The ovum, at the earliest period of its existence, or rather as soon as it becomes the object of even the assisted sight, appears like a small vesicle, slightly attached to some part, generally the fundus of the uterus; and, on examination, all the organs of which it consists are confusedly blended. They by degrees appear more distinct; and in the more advanced periods we discover the membranes already described in the articles AMNIOs, CHORION, and DECIDUA, q. v. The decidua forms apparently, at first, the principal bulk of the ovum, and is, as we have said, double; the outer membrane lining the uterus, and the inner, reflected, covering the ovum: the double chorion is the only membrane of the ovum which is properly a part of the mother.

In the early period of gestation, a white speck is observed on the amnios, near the part where the umbilical vessels are inserted. It is a vesicle filled with a white liquor called *vesicula umbilicalis, alba* or *lactea*, and united with the umbilical cord by a funis, consisting of an artery and vein. It disappears in the progress of gestation, and we are unacquainted with its use.

Though the bag or external parts of the conception are at first large in proportion to the fœtus, they are afterwards related in an inverted ratio; the fœtus increasing more rapidly than its contents and accompaniments: the latter seldom become more bulky after the seventh month. The fœtus is, for a time, invisible; and when at first seen, resembles, as we have remarked, a tadpole, with a rounded head, from which a tail projects. This tail does not consist of what are afterwards the inferior extremities, for these only appear to sprout after some months; nor is it the superior extremities in embryo, for these apparently are added at the sides. When we can perceive any addition, we find a very minute moving point, somewhat below the head, which expands into a heart, at first conveying an almost colourless fluid, and afterwards red blood. Two large black points, the eyes, seem to project, after some time, from the head of the tadpole, and almost to cover it: a chasm is seen below, the future mouth; and a disproportionately large abdomen is soon conspicuous. As we find all these important organs accessory, or rather evolved at a subsequent period, we must consider the early formation, or the parts first evolved, as the most important. These can be only the brain and spinal marrow, each essential to the existence of the animal, and the motion of the heart, on which life depends. All the other organs probably exist at the earliest period, but are invisible from their minuteness and pellucidity. The muscles and membranes have their primordial stamina in the nervous system, and the fibrils are probably convoluted and compressed. What we style evolution, then, is only extension; and the bulk or size of an organ is limited by their length, and their capacity of admitting the interposition of inorganized matter.

We can see an obvious instance of increased bulk by the interposition of such matter, if we trace the fibres of the stem of an apple, expanding to the bulk of the fruit.

A fœtus of four weeks is near the size of a common fly; soft, mucilaginous, and, in appearance, suspended by the belly; its bowels covered by a transparent membrane. At six weeks, it is of a somewhat firmer consistence, nearly the size of a small bee; the extremities then begin to shoot out. At three months its shape is tolerably distinct, and it is about three inches long. At four, five, and six months, it is five, near seven, and near nine inches respectively. In the successive months it increases in length to twelve, fifteen and twenty, or twenty-two inches, though varying in different women, and in different births. Indeed all these measurements are rather approximations than accurate representations.

Of the membranes we need not again speak, but merely to remark that the ovum is contained in the double decidua, as the head in a doubled night cap, and that each is probably an inspissated exudation at different periods from the uterus (*Scarpa*). Between the chorion and amnios, in the early months, a collection of gelatinous matter is found; perhaps with the vesicula lactea, to assist in the nutrition of the fœtus, while the circulation is yet incomplete; and in the latter, this space is occasionally filled by a serous fluid, styled the false waters; so that every discharge of water, in pregnant women, is not dangerous. If not attended with a discharge of blood, it is apparently harmless. These waters, however, have led some physiologists into an error, who supposed, that they had discovered a receptacle for the urine, called in quadrupeds the *allantois*, an oblong membranous sac between the chorion and the amnios. No such receptacle, however, is found in the human subject.

The placenta, as we shall afterwards show, consists of two parts. One is apparently derived from the decidua, and has been supposed a spongy inorganic substance, for the purpose of attachment; but it contains numerous blood vessels which can be injected exclusively from the arteries of the mother. The remaining part of the cake is an organ of the fœtus, and its vessels can only be injected from the umbilical cord. These facts, which are now well established, prove that no circulation is carried on between the mother and fœtus in continuous vessels; nor can any considerable nerves, indeed scarcely any, be traced from the uterus to the fœtus part of the placenta. The fœtus has therefore a system peculiarly its own in every respect, indebted only to the mother for support, warmth, and a supply of nutriment.

When the blood, through the funis umbilicalis, reaches the abdomen of the fœtus, it is carried to the liver; and one half of the whole mass circulates in that organ. In the earliest stages, the liver is peculiarly large; and this considerable proportion of the vital fluid is seemingly designed to nourish it, for the bile is colourless, and without taste. This viscus does not indeed lessen, but its proportion is diminished by a more rapid increase of the other parts, and in every organ where a peculiar organic structure is necessary nature seems to form it very early of a large size. This is the case with the eyes, the liver, the lymphatic system, &c.; nor, when the relative sizes are considered, is the

genital system of either sex an exception. The remainder of the blood is carried by the ductus venosus to the vena cava, where also the blood, after having circulated through the liver, arrives. We thus trace it to the right auricle; but, as the lungs are not yet expanded by air, the pulmonary system cannot contain the whole quantity, and one part, but its proportion is not exactly known, passes through the foramen ovale, a hole in the septum, which divides the auricles. The rest proceeds to the right ventricle; but of this portion only a part enters the pulmonary artery for the reasons assigned, and the rest is conveyed to the aorta, through a duct styled the *ductus arteriosus*. Thus the entire mass of fluids is conveyed to the aorta, to be circulated through the whole machine.

The nutrition of the fœtus has occasioned many controversies. We may just mention a friendly one between the first Dr. Monro and Mr. Gibson, in the first and second volume of an excellent collection, though too much neglected, the Medical Essays of Edinburgh; because they contain a greater variety of facts, respecting the fœtus, than are to be found in any other work. The subject may now be drawn within a narrow compass. The fœtus is probably not nourished by the liquor amnii, because this fluid is not nutritious; it contains but a small portion of animal gelatine, and a large one of neutral salts, and is rather excrementitious than wholesome. If employed for this purpose, it probably is not swallowed, since there are no fœces collected in the bowels, for the meconium is only the inspissated bile, and other fluids of the intestines, which have acquired a colour from the delay; and no allantois to receive an excrementitious discharge. It is not probably absorbed; for the surface of the fœtus when born is covered with mucus, apparently designed to prevent its irritation. This fluid, however, is now found to belong to the fœtal part of the ovum; so that were every fact adduced in support of the nourishment of the fœtus by the liquor amnii to be admitted, we must still seek for a supply. This supply is undoubtedly afforded by the mother; but it is still doubtful whether in the maternal part of the placenta the blood undergoes any preparation. We know of none; we can perceive none: it is apparently deposited in cells, and again absorbed.

Since, then, the connection of the fœtus and the mother is so slight; since there are no continuous vessels, and scarcely any, if any, nervous communication; what reason can be assigned for the reported influence of the mother's imagination on the child, either in impressing any peculiar mark, more essentially changing an organic structure, or mutilating it, in consequence of seeing similar objects? Such INFLUENCE IS WHOLLY UNFOUNDED; THE OFFSPRING OF FANCY, SUPPORTED BY ACCIDENTAL FACTS, OFTEN BY DESIGNED MISREPRESENTATIONS. Sound physiology denies every such connection; nor can it be established, without admitting a connecting ether or aura, which on any change made in the mother's system is followed by a corresponding one in the fœtus. We shall leave the establishment of such an aura to the visionary supporters of sympathetic medicine, or the modern dreamers, who believe in animal magnetism. No such exists, or at least the influence of no such medium can be perceived.

If we examine the various facts adduced, the marks, for instance, we shall find that they are as often seen without any previous affection of the imagination as with it; that the resemblance, when such fancies have occurred, is distant, and often imaginary. If we look at the changes of organization, we shall find, often, that the shock has taken place when the bones were firmly united, and when the disposition could not be changed without violent mechanical force: the fact mentioned by father Malebranche, where the limbs of the fœtus were fractured, from the mother seeing a criminal broken on the wheel, is evidently false, or the circumstances greatly misrepresented. When, in the advanced period of gestation, the sight of a mutilated person is apparently followed by a similar mutilation of the child, the influence of the sight is highly improbable. What becomes of the mutilated limb? It may be supposed to be deprived of life, and absorbed, since it is never found; but the time required for such a process is far beyond the whole period of gestation, and the putrid limb, long before it would be completed, must produce a fever of the worst kind, for it must be remembered that the fœtal blood returns to the mother. We might allege, that of ten thousands exposed to such sights, in perhaps only a single instance will the supposed consequence follow; and that it sometimes occurs without the previous spectacle. When both then happen, the concurrence must be pronounced accidental only. It is evident, however, that the fœtus is affected by the complaints of the mother. It has in many instances shared her eruptive diseases; sometimes seemingly her fevers; more probably her nervous complaints. If, with the little connection which we have shown to take place, it can partake of these diseases, it may be supposed to suffer more essentially, or it may appear that we have too rashly denied any nervous communication. These influences are, however, much less considerable than authors have supposed. The agitations of the nervous system must be conveyed to an organ so peculiarly irritable as the uterus, and any spasmodic contractions of that organ must be felt by the fœtus. The additional warmth also of the blood, in fever, may be supposed to affect the irritable little being, not yet born; and the matter of the small pox, which we can only trace, because this of all the febrile exanthema alone leaves any cicatrix, may undoubtedly be absorbed from the maternal part of the placenta. Nature, however, seems to have anxiously guarded against any communication, and the child often survives uninjured the most violent diseases of the mother.

The changes from the fœtal state take place from the moment the child breathes; but the cause of its breathing has puzzled the ablest physiologists. The necessity of taking breath has been attributed to irritation, to an "appetite for air," and to innumerable fancied causes. The real cause appears to be change of position. The fœtus, in the womb, assumes that position, which the superior strength of the flexor muscles produces. The body is bent forward, the knees drawn up, the legs backward, the arms across the body, and the fingers clenched. When the position is altered the ribs are raised, and the abdominal viscera fall down. A vacuum is the consequence in the lungs, which the air rushes in to supply. The sensation of uneasiness induces the necessity of expelling the air; and the same

causes concur to bring on the repetition of breathing, which, from the uneasy feeling excited by the necessity for inspiration and expiration, is regularly continued.

In consequence of the expansion of the lungs, a larger portion of blood is carried into that organ; the right ventricle is more completely emptied, and the impetus which kept the foramen ovale open, and which carried the blood through the ductus arteriosus, is lessened; they gradually contract into ligaments, and the whole of the fluid, brought by the veins, is carried through the lungs. When the supply from the umbilical cord is cut off, the ductus venosus contracts in the same way, and the vena portæ receives the blood from the returning veins of the abdominal viscera, as in the whole extent of the future life.

The fœtus differs, in many respects, from the adult, even after the changes enumerated have taken place. The head is very large in proportion to the rest of the body, the bones of the head soft and yielding, the sutures not yet formed, and a triangular space is left at the union of the coronal and sagittal sutures. The bones of the trunk, the extremities, and all the articulations, are remarkably flexible. All the protuberances of bones (apophyses) are distinct osseous portions, united by cartilages (epiphyses); the heads and condyles of bone, as well as the brims of cavities, are cartilaginous.

The brain and spinal marrow, the glandular and sanguiferous systems, are, we have said, larger than in the adult. A gland, peculiar to the fœtus and infant, is found at the upper part of the mediastinum, between its folds, which disappears in advanced age, and is apparently connected with the lymphatic system. The kidney is also divided into distinct lobes, as in brutes.

In the fœtus, the cavity of the thorax is, as may be expected, less than after respiration; the lungs are smaller, more compact, and of a red colour like the liver. The abdomen is disproportionately large, and the extremities particularly small.

It has been supposed, that if a child, who has only once or twice breathed, be thrown into water, the foramen ovale may continue open, and he may enjoy the advantages of living in air or under water. This idea is supported by the remark, that negroes are excellent divers, and that they are usually plunged into water as soon as they are born. The supposition is not impossible, but has never been reduced to practice. We have a faint recollection of the experiment having been tried on puppies without success.

The extra-uterine fœtuses are lodged either in the ovarium, in the Fallopian tubes, or in the cavity of the abdomen. One instance is recorded where the fœtus was found in the cavity of the abdomen, the uterus, Fallopian tubes, and ovaria, being at the same time in an unaltered state, similar to what happens where impregnation has not taken place. This and other appearances will, however, be readily understood, when we speak more particularly on the subject of GENERATION, q. v. (See Medical Memoirs, London, vol. iii. p. 176.) When extra-uterine fœtuses die, the weight, after some time, occasions an irritation, and an abscess is formed, by which the child generally comes away by parts. See instances recorded in the London Medical Observations and Inquiries, vol. ii. and iii. See also Dr. Hamilton's Outlines of Midwifery; Haller's Physiology;

Sabatier's Description of the Fœtus; Wrisberg's Observationes Anatomicæ; and Dr. Hunter's Tables.

FOLIA'CEUM ORNAMENTUM, (from *folium, a leaf*). The fimbriated part of the Fallopian tubes. See TUBÆ FALLOPIANÆ.

FOLIA'TA TERRA, (from its resemblance to *folium, a leaf*). See SULPHUR.

FOLIA'TIO, (from *folium, a leaf*), the disposition of the nascent leaves within the bud, differently distinguished according to the disposition of the leaves. See Martin's Botanical Dictionary.

FOLIUM, (from *φύλλον, a leaf*). A LEAF; called *folium*, to distinguish it from the leaf of a flower, which is called *petalum*. See PETALA.

A leaf is termed: 1. *Folium abruptum pinnatum*, abruptly pinnate, when they have neither leaflet, nor tendril, nor clasper at the end. 2. *Acinaciforme*, sabre-shaped. 3. *Acuminatum*, awl-winged, or *Integerrimum*, entire. 4. *Acutum*, acute. 5. *Bifidum*, bifid. 6. *Binatum*, two lobed. 7. *Canaliculatum*, channelled. 8. *Cartilagineum*, cartilaginous. 9. *Ciliatum*, ciliated. 10. *Cirrhous*, winged leaf. 11. *Conjugatum*, conjugated. 12. *Cordato hastatum*, heart arrow pointed. 13. *Cordatum*, heart shaped. 14. *Crenatum*, crenated. 15. *Crenatum acutum*, acute crenated. 16. *Crenatum duplex*, double crenated. 17. *Crenatum obtusum*, obtuse crenated. 18. *Crispum*, curled. 19. *Cuneiforme*, wedge shaped. 20. *Decompositum*, decomposite. 21. *Decurrens*, running winged. 22. *Deltoides*, deltoid, resembling the Greek Δ. 23. *Digitatum*, resembling a hand with the fingers extended. 24. *Dolabriforme*, hatchet shaped. 25. *Duplicatio pinnatum*, vel *Pinnato pinnatum*, doubly winged. 26. *Duplicato serratum*, doubly serrated. 27. *Erosus*, eroded. 28. *Hastatum*, pike, or javelin shaped. 29. *Hispidum*, thorny, stinging. 30. *Integerrimum*, perfectly entire. 31. *Lacerum*, lacerated, or torn. 32. *Lancinatum*, jagged. 33. *Lanceolatum*, spear shaped. 34. *Lineare*, linear, narrow. 35. *Linguiforme*, tongue shaped. 36. *Lunatum*, moon shaped. 37. *Lyratum*, lyre shaped. 38. *Nervosum*, nervous, fibrous. 39. *Oblong*. 40. *Obtuse*. 41. *Obtusum cum acumine*, blunt pointed. 42. *Orbiculum*, round. 43. *Ovatum*, oval. 44. *Oval*, or *Elliptic*. 45. *Palmatum*, palmated. 46. *Papillosum*, warted. 47. *Pilosum*, piled, or like velvet. 48. *Pinnatifidum*, wing pointed. 49. *Pinnato pinnatum*, double winged. 50. *Pinnatum abruptum*, abrupt winged. 51. *Pinnatum cum impari*, winged, with one pinna in excess. 52. *Plicatum*, plaited. 53. *Præmorsum*, bitten. 54. *Quinque angulare*, five-cornered. 55. *Quinque partita*, divided into five parts. 56. *Racemosum*, branching. 57. *Reniforme*, kidney shaped. 58. *Repandidum*, notched. 59. *Rugosum*, wrinkled. 60. *Sagittatum*, arrow pointed. 61. *Serratum*, sawed. 62. *Sinuato dentatum*, indented, sinuated. 63. *Sinuatum*, sinuated. 64. *Subrotundum*, roundish. 65. *Subulatum*, awl shaped. 66. *Supra decomposite*. 67. *Teres*, taper. 68. *Ternatum*, trifoliate. 69. *Tomentosum*, downy. 70. *Triangulare*, triangular. 71. *Trilobum*, trilobated. 72. *Triplicato ternatum*, triply trifoliate. 73. *Wing leaf*, with membranous foot stalks.

Leaves consist of a parenchymatous matter dispersed in the meshes of a net work, and the whole is covered by an expansion of the epidermis of the pedicle or foot-stalk. The upper pagina of the leaf seems designed to throw off the excrementitious exhalations of the plant,

and the under to imbibe moisture. It is necessary for these purposes that the light should have access to that part which is designed for the separation of the oxygen; and if a leaf is forcibly turned, by an opposite curvature of its foot stalk, it restores the upper pagina to the sun's rays. Leaves have been consequently supposed to bear some analogy to the lungs of animals.

FO'LIUM. It is the name of the philosopher's stone: and of that triangular membranaceous sinus, where the sagittal and coronal sutures in infants meet: it signifies a relaxed uvula in Arnaldus. See also **DEXAMENE**.

FO'LIUM, called also *fol.* *Indum, malabathrum, malabattrum, tamalapatrum; cardegi Indi; catou-karua, pseudocassia*; **INDIA LEAF**; is of a firm texture, of an oblong oval shape, pointed at both ends, smooth and glossy on the upper side, and less so on the under; of a yellowish green above, and of a pale brownish colour beneath, furnished with three ribs running its whole length, one very protuberant on the lower side, and two smaller ones which bound the edges. Both the leaves and their pedicles are very mucilaginous; chewed, they render the saliva slimy or glutinous; infused in water, they yield a large quantity of strong tenacious mucilage; but they possess little of the strong aroma of the bark. These leaves, according to Ray, are diuretic. It is an ingredient in the theriaca, and supposed by Bosc, from an examination of different specimens, to be the leaves of the *laurus cassia* Lin. Sp. Pl. 528. See Lewis's *Materia Medica*.

FOLLI'CLUS, FOLLIS, (from *φαλλος, a bag*). **A FOLLICLE,** a little bag; called also *crypta*. It is likewise the name of a large leathern bag, filled with wind, and used as an exercise by the ancient Romans. In surgery, it is a bag which contains the matter of abscesses and tumours, and the meliceris; in botany, the thin involucre or membranaceous cover which incloses the seeds of plants; in anatomy, a simple gland. See **GLANDULA**.

FOLLI'CLUS FE'LLIS. See **VESICULA FELLIS**.

FOMENTA'TIO. See **FOTUS**.

FO'MES, (from *fovendo*). **FEWEL.** When spoken of in diseases, it is the remote cause of the disease; most commonly the material, efficient cause. In the plural, *fomites*, it is generally applied to the infection contained in woollen or cotton, and rendered more deleterious by confinement.

FO'MES VENTRICULI. See **SPLEN**.

FONS PHILOSOPHO'RUM. **THE PHILOSOPHER'S FOUNTAIN;** the *balneum Mariæ*.

FONS PU'LLANS, vel PULSA'TILIS. See **FONTANELLA**.

FONTA'LE ACETO'SUM. See **ACIDULÆ**.

FONTANE'LLA, in anatomy, is the membranous part found in new born infants at the meeting of the coronal and sagittal sutures, and which at last ossifies. It is called *fons pullans*.

FONTANE'LLA, (a diminutive of *fons*, also *fonticulus*). **A LITTLE FOUNTAIN.** In surgery, it is metaphorically used to signify the small aperture called an *issue*. Issues were made in Hippocrates' time, and have maintained their credit down to the present day. The parts where issues are generally made, are, 1st, on the coronal suture, just where it joins the sagittal; but a perpetual blister on this part is to be preferred: 2dly, the neck: 3dly, the arms, near the lowest part of the

deltoid muscle, in the interstice between it and the biceps muscle.: 4thly, above the knee, on the inside of the thigh, in a hollow, which may easily be perceived by the finger: 5thly, below the knee, on the inside of the leg, where there is a space between the muscles, filled with cellular substance: 6thly, on the back; but the fifth would be more useful and less troublesome, if placed above the knee.

The method of making an issue is, first to mark the part with ink; then the operator and an assistant having raised the skin with their fore-fingers and thumbs, the operator pushes a lancet through the skin, to make an opening spacious enough to receive a pea, or a larger substance if necessary. This is introduced and secured by a sticking plaster and bandage: it must be renewed every twenty-four hours.

A caustic is sometimes applied, and continued six or eight hours; the eschar cut, and a pea inserted. The caustic, in some instances, is allowed to slough off, and the discharge continued by means of a pea.

Instead of common peas, wooden or silver balls are sometimes employed to promote the discharge; at others the dried oranges, called orange peas, or pieces of gentian or orris roots cut to a proper size.

Issues resemble, in some part of their effects, blisters, and, like them, produce benefits very disproportioned to their discharge. They act, however, slowly, and are more applicable to chronic than acute diseases. They produce a less considerable, and often a less effectual, discharge than setons; but are more cleanly and less painful. When any acrimony occurs in the fluids, for, on some occasions, such must be allowed, the drain of an issue is highly useful; and it appears strikingly so from inflaming and discharging at those times when this acrimony is usually deposited on the surface. When considerable determinations of blood to the head occasionally take place, two large issues will often prevent the attack; and in this case, too, they discharge more violently at the expected period of suffering. In chronic inflammations of the bones, issues are of considerable importance. In those enlargements of the bones, which are observed in scrofula, they are of service; and in those of the vertebræ, which produce distortion, they are valuable remedies. (See **DISTORSIO**.) In gout, they seem often to prevent the too frequent returns of paroxysms, and we are led to employ them from a similar effect of those drains which arise from chalk stones. In nervous affections they are highly salutary, particularly in some cases of epilepsy; and in angina pectoris, Dr. Macbride thinks that they have been of service when put in the thigh. They were formerly often used to prevent complaints, particularly in children; but they are now found to be troublesome and unnecessary.

Issues are formed with great advantage when we would heal ulcers of long standing. In many cases, after the ulcers are healed, the issues may be gradually diminished, as the constitution improves; but even then, to dry up the issue hastily would not be judicious, as many disagreeable, and sometimes fatal, effects have been the consequence. See *Bell on Ulcers*, ed. 4. p. 140; his *Surgery*, vol. 4. p. 376, 384. *White's Surgery*. *Lera on the Theory of Issues*; and *Hoffman*, vol. vi.

FONTICU'LUS, (from *fons, a fountain*). See **FONTANELLA**.

FORA'MEN, (from *foro*, to pierce). AN HOLE. See OS and CAPUT.

FORA'MEN CÆ'CIUM. The name of a hole in the middle of the tongue. See LINGUA.

FORA'MEN GRÆCUM; an opening in the basis of the skull, between the ethmoidal and frontal bones, through which a small vein passes.

FORA'MEN LA'CERUM. See CAPUT.

FORA'MEN OVA'LE. See COR.

FORAMINULENTUM OS, (from *foramen*, a hole). See ETHMOIDES OS.

FORCEPS, PINNERS; (quasi *ferriceps*, from *ferum* iron, and *capio*, to take hold). A small forceps is called *volsetta*. A surgeon's instrument of numerous and varied uses. The small forceps are employed to take hold of small parts, to remove dressings, or minute bodies, for which the fingers cannot be conveniently employed. Larger ones are used to extract bullets from wounds, polypi from the nose, calculi from the bladder, and occasionally the fœtus from the vagina and uterus, when advanced so low as to be conveniently reached, and the pains from debility or other causes are slack and inefficient. In each case their forms are different, but they can only be properly considered when we treat of each subject.

See Heister's Surgery. Mulder on the Forceps and Lever. Vide EMBRYLCA.

FORMA. FORM; opposed to substance or essence; as formal is to material. Thus a spasm is a formal cause of inflammation; a thorn a material cause.

FORMIAS, (from *formica*). FORMIATE. Salts produced by the union of formic acid with different bases; not used in medicine.

FORMICA. The name of a black wart, with a broad base, and cleft superficies; because the pain attending it resembles the biting of an ant: a varicose tumour also on the anus and glans penis.

FORMICA MILLIARIS. See HERPES.

FORMICA MINOR, (*quia ferat micas*; because of its diligence in collecting small particles of provisions together).

Parvula (nam exemplo est) magni formica laboris.

Ore trahit quodcumque potest, atque addit acervo.

THE ANT, or PISMIRE. This little insect, supposed to have greater strength in proportion to its size than the elephant, contains an acid which seems to occasion the uneasiness on our skins when they are said to have stung us. A gross oil is obtained by expression, after distilling them in water; and an essential oil arises with the acid liquor in distillation. The formic acid, obtained by distillation and washing the red ants in water, when concentrated, has a penetrating smell, and is corrosive; but its taste is so agreeable when greatly diluted with water, that it has been proposed to be used instead of vinegar.

The expressed juice of these little animals has been recommended to render baths stimulating, and employed in rheumatism; and an ant's nest bruised has been applied to the parts affected with rheumatic pains. The oil of ants has never been used. The quantity of acid to be obtained from them is nearly half their weight, and Fontana found it to approach very near the carbonic acid. See Lewis's Mat. Med. Neumann's Works.

FORMICANS, (from *formica*, an ant). CREEPING; an epithet bestowed by Galen on a low unequal pulse.

FORMIX. See HERPES EXEDENS.

FORMULA, a diminutive of *form*, and applied to the form of a medicine. The distinctions were formerly numerous and minute; the appellations varied from trifling accidental circumstances. We need not follow the singular fancies of Morellus, and some of his predecessors, but the most modern and useful author is Gaubius. He divides formulæ into *internal* and *external*. The former are either *solid* or *liquid*. The solid formulæ are *powders*, *boluses*, *electuaries*, *linctuses*, *pills*, *lozenges*, and *cakes* (*Rotuli*). The liquid formulæ are *infusions*, *decoctions*, *expressed juices*, *emulsions*, *mixtures*, *juleps*, *smaller mixtures*, and *draughts*. The julep is a dilute pleasant mixture, and decoctions were sometimes called *apozems*.

The external formulæ are *injections*, *aspersions*, *epithems* and *cataplasms* of different consistence; *baths*, *vapours of burnt bodies*, *plasters*, *cerats*, *ointments*, *odoriferous balsams*, *liniments*, *blisters*, and *frictions*. Formulæ, directed to the head, were *cucuphæ* (*caps*), *frontalia* applied to the forehead, and *collyria* for the eyes. Applied to the nose, *errhines* and *perfumes*; to the mouth and throat *dentifrices*, *stimulants* to produce a discharge of saliva (*apophlegmatismi*) and *gargles*; to the stomach *scuta*; to the anus *clysmata* and *suffusatorium*, to the vagina *pepsi*.

These are nearly retained, but not in all their variety; and the directions for each, so far as directions are necessary, may be found under their respective heads. In works of this kind it has been usual to add formulæ; but these can be only examples, and the simplicity of modern practice scarcely requires such. They are usually the refuge of quacks, and of those ignorant practitioners who direct a remedy to the name of a disease, and copy a form which they employ indiscriminately: for these reasons we have seldom introduced them, though we have offered every necessary hint to avoid heterogeneous mixtures. Should formulæ, however, be required, we will add them in an appendix.

FORNAX, (from the Arabic term *for*,) *Fornus*. A FURNACE. Furnaces are chemical instruments to expose conveniently any body to the degree of heat required. In all furnaces, we must endeavour, 1st, to confine the heat as much as possible to the object; 2dly, to prevent its being dissipated; 3dly, to produce the heat required with as little fuel as possible; 4thly, to be able to regulate the degree of heat according to our wants.

Of furnaces there are a great variety invented by chemists for the performance of their operations, which may be seen, with their constructions and uses, particularly in the Encyclopædia Britannica, under the article Chemistry; Lavoisier's Elements of Chemistry; and Dr. Black's Lectures. Unfortunately, we have no Dictionary of Chemistry to refer to; and the object is not so properly medical as to induce us to enlarge on it. See also ATHANOR, BALNEUM MARIE; and Dr. Lewis's Commercium Philosophico-technicum, part the first.

FORNICATUS, (from *fornix*, an arch or vault). Fornicated petals are such flower-leaves as are arched, like the roof of the mouth, as the crest of clary or sage.

FORNIX. See ACHICOLUM.

FORNIX, (from the Arabic term *for*,) is part of the corpus callosum in the brain, and called from a

distant resemblance that it hath to the arches of vaults. See CEREBRUM and LYRA.

FO'RTIS, A'QUA, is a name which artists have given to the nitrous acid, from its dissolving power. See NITRUM. It is also called *Elephas*.

FO'SSA, (from *fodio, to dig*). A DITCH. In anatomy it is synonymous with *fossa navicularis*.

FO'SSA NAVICULA'RIS. See AURICULA.

FO'SSA MA'GNA. The interior cavity of the pudendum muliebre, obvious on a separation of the labia.

FO'SSA PITUITA'RIA. See SELLA TURCICA.

FO'SSILIS SAL. See GEMMÆ SAL.

FO'SSILUS. A name of the *tibia*, and of the *fibula*.

FO'TUS, or FOMENTATIO, (from *foveo, to cherish*,) *embroche*. *Thermasma*, *chiliasma*. To foment, is to cherish with heat, to bathe with warm liquors; though dry powders, parched barley, or oats in bags, liquids in a bladder, or in a sponge, applied warm to the diseased parts, are also named fomentations. They are usually, however, fluids externally applied, as warm as the patient can bear them, in the following manner: two flannel cloths are dipped in the heated liquor, one of which is wrung as dry as the necessary speed will admit, then immediately applied to the part affected: it lies on until the heat begins to lessen, and the other is in readiness to apply when the first is removed. This alternate application is continued fifteen or twenty minutes, and repeated two or three times a day. If there is a wound, it is usually defended by a piece of thin cloth.

Every intention of relaxation and soothing by fomentations may be answered by warm water alone; but when discutients or antiseptics are required, the suitable ingredients must be added. Fomentations of warm water are not, however, employed as relaxants only. They are applied with advantage to contracted limbs, to indolent abscesses, foul ulcers, and sometimes to bruises. In these instances the stimulating power of the heat is useful to excite the action of the torpid vessels. See BALNEUM.

The common fomentation is a decoction of camomile flowers, in the proportion of an ounce to a quart, and it is often preferred to the *decoctum pro fomento* of the London College. R. Abrotani exsiccati; absinthij maritimi exsiccati, camæmeli exsiccati, singulorum, p. ʒi. foliorum lauri exsiccatum, p. ʒij. aquæ distillatæ m. ℥6. paulisper coque et cola. The preference is given to the former, on account of its being less complicated, and that little benefit is derived from the numerous ingredients.

The degree of heat should never exceed that of producing a pleasing sensation, except when employed as a stimulus: great heat produces effects very opposite to that usually intended by the use of fomentations.

FO'TUS ANODY'NUS. See ANODYNUM.

FO'VEA, (a *foveo, for fodio, to dig*). In anatomy it is the sinus of the pudendum muliebre. In the bath rooms it is a sudatory for receiving one or both the legs, in order to sweating.

FOVI'LLA, a fine substance imperceptible to the naked eye, exploded by the pollen in the anthers of flowers.

FRACASTO'RII SPE'CIES, i. e. pulv. èbólo, (from *Fracastorius*, the inventor). See BOLUS, CONFECTIO, and DIASCORDIUM.

FRACTURA, (from *frango, to break*). *Catagma*;

classis; clasma; agme. A FRACTURE. Dr. Cullen places this genus of disease in the class *locales*, and order *dialyses*; and defines it part of a bone having its cohesion destroyed by violence, and separated into large fragments.

Fractures are differently denominated, according to their direction; as a transverse, oblique, or longitudinal fracture. When one bone is broken in one place only, and no remarkable injury is perceived in the adjacent parts, it is called a simple fracture: when a bone is broken in more parts than one, or when two bones that are joined together, as the radius and ulna, are both broken, it was formerly called a compound fracture; but the term is now confined to those fractures in which the external integuments are penetrated by the end of the fractured bone. If with a fracture there is a dislocation, or a wound, it is then a complicated fracture. In fractures, the reunion of the separate parts of the bone is by a renewal of the organical bony substance, and not by a glutinous matter, which hardens into what is called callus.

Fractures are discovered by the eye, the ear, and touch.

The period in which the reunion may take place is influenced by the constitution, and many different circumstances. In pregnant women, a cure is sometimes not effected until after delivery; see London Medical Observations and Inquiries, vol. iv. and Hildanus mentions three cases of this kind: but the reunion sometimes takes place even in these circumstances. A scorbutic or a venereal taint may prevent the bone from healing, or a caries may retard the union; if a wasting of the limb, or a palsy, comes on, the cure will be slow, if ever effected. If a fracture happens in a bone over which an ulcer hath long continued, it is very difficultly united. A fracture in the cranium, vertebræ, ribs, sternum, os ilium, or os pubis, is dangerous, on account of the vicinity of the brain, spinal marrow, or other viscera.

If called after the tumour or a violent inflammation be come on, the extension must be deferred until these are removed; but if these symptoms are slight, reducing the limb may prevent their increase. If there is a wound, all extraneous matters should be removed at the first dressing, and all strictures lessened; if the wound is too small, it should be dilated; and, if possible, this should be done before inflammation comes on, as the parts are then more sensible; and if it can be effected without altering the relaxed state of the limb, a circumstance of such importance that hardly any thing should interfere with it, the dilatation should be made so that the discharge may be depending. Indeed, every means of preventing the matter accumulating in a depending part should be avoided. If a bone protrudes, a portion should be sawed off, unless it can be easily reduced; an operation but little troublesome. If a luxation accompanies a fracture, it should first be reduced, and afterwards the fractured bones replaced, though, if the fracture be very near the head of the luxated bone, the luxation may be left till the fracture is healed.

When a simple fracture happens, the bones should be replaced, and the limb laid in an easy state, slightly bent: the reduction was called by the Greeks *ca-thidrustis*. A cataplasm of oatmeal, oil, and vinegar, or, as a substitute, a plaster of ceratum album, should be next applied. The bandage with eighteen tails is the best, both in simple and compound fractures; it is more

commodious than the roller, as it allows of viewing the limb without disturbing it. At the conclusion, if the leg is œdematous, cold pumping, the lace stocking, and daily rubbing with a flannel, will restore the natural state of the limb.

Compound fractures are often attended with mortification; but this should not always hasten amputation. When any tendency to this symptom appears, a fomentation of a strong decoction of camomile flowers and wormwood, in which sal animoniac has been dissolved, sprinkling the flannels with a strong camphorated spirit at the time of applying it, should be used. The wound should be dressed twice a day, the part wrapped up with a warm cataplasm, and bladders about one half full of warm water applied, to keep up a proper warmth. The bark joined with rhubarb, in some cases with nitre, and in others with opium, camphor, volatile alkali, and snake-root, should be given.

When amputation seems necessary, we should consider whether life will not be endangered if it is omitted. It is impossible in some instances to know immediately whether a limb can be saved. However, when a bone or bones are broken into many pieces, and to a considerable extent, as is frequently the case when the accident happens from cannon shot, broad wheels of carriages, &c. when the soft parts are so torn and bruised as to render a mortification of the part a probable and immediate consequence, amputation will be necessary without delay. If the ends of a bone, or two bones, by which a joint is formed, be crushed, and its ligaments considerably injured, amputation cannot with propriety be deferred. Some instances of compound fractures also require speedy amputation; for an inflammation seizing the limb tends quickly to gangrene, and the progress is usually rapid. Instead, therefore, of waiting for a separation of the mortified from the sound part, or to try what art can effect, the operation is immediately necessary. A very short time makes all the difference between probable safety and death. If in a compound fracture this inflammation hath taken place, and hath continued some hours, amputation would destroy; and the only chance is to use such regimen as appears to be indicated; and when this has no further use, then to support the patients with cordials, wine, and bark. Again, inflammation may not run high; yet frequently there are collections of matter, which after several openings recur: the patient, instead of being recruited, wastes by the discharge, hath night-sweats, loses his appetite and strength. In these cases the bones continue disunited, and amputation at last is necessary. Mr. Pott observes, that in compound fractures there are three points of time in which amputation may be requisite. 1st, Immediately, or as soon as possible after receiving the injury; 2d, when the bones continue long without any disposition to unite, and the patient's strength failing from the discharge, death apparently impends; 3d, when a mortification shall have taken such complete possession of the inferior part of the limb, down to the bone, that, upon separation of their parts, the bone or bones would be left bare in the intermediate space. The necessity of early amputation in these cases arises from the ill effects of a greatly obstructed circulation, from the destruction of numerous vessels. The pain, irritation, and the admission of air, also produce considerable fever and inflammation, which quickly terminate

in gangrene and death. If a joint is injured, the danger is increased; as the pain and irritation, with the subsequent inflammation, from the admission of air into the cavity, are greater. If possible, then, the operation should be determined on before inflammation approaches; for, if this has taken place, it will be too late. In the second instance, the particular time for amputation must be determined by the patient or his friends; for, with the surgeon, it is not choice, but necessity. In the third instance, the time requires no consideration; for if the soft parts are destroyed, either the surgeon must saw the bones, or they must be left to separate. In either case the patient loses his limb. These are some of the principal instances which determine in favour of amputation; experience, and the several authors who have written on this subject, will suggest others, and amongst these may be consulted Pott's Works, with his pamphlet entitled Remarks on the Necessity, &c. of Amputation in certain Cases; Gooch's Works; Observations on Mr. Pott's General Remarks on Fractures, by Thomas Kirkland, Surgeon; and the Systems of Surgery, by Bell, Dease, Kirkland, &c.

Fracture of the carpus.—These bones are small, and rarely broken; and when fractured, they cannot be properly replaced, nor will they consolidate. The ligament and tendons are also generally so much bruised, that the joint of the hand becomes rigid; abscesses, fistulas, and caries, generally ensue, and relief is seldom obtained but by amputation of the hand. An attempt may be made by two assistants extending, while the surgeon endeavours to replace the fractured bone or bones. White's Surgery, p. 145.

Fracture of the clavicle.—Whatever part of the clavicle is broken, the part which joins the scapula descends below that which is fixed to the sternum, on account of the weight of the arm. When this bone is fractured, the patient cannot lift his arm; it hangs inclined toward his breast, and, from a slight motion of the humerus, the fracture in the clavicle will be evident to the touch, sight, and ear. To reduce this fracture is easy, but to retain the bones in their proper situation more difficult. An assistant should place his knee between the scapulæ of the patient, and with his two hands draw the shoulders back: the clavicles will be thus extended; and the surgeon, standing before the patient, must reduce the ends of the bone, by raising the arm to its proper situation, instead of loading the end next the sternum with compresses to bring down the rising end of the bone. A narrow but thick bolster is then to be applied above and below the clavicles, to fill up the cavities; upon these two narrow bolsters, in the form of the letter X, are to be laid; and over the whole a piece of thick paper moistened with vinegar. A wad of tow, or a ball made of soft rags, is put under the armpit, next to the fractured end, for the support of the shoulder; the bandage to keep the bones from moving, and a sling is fixed about the neck, to suspend the arm. See Bell's Surgery, vol. vi. p. 59. White's Surgery, p. 138.

A fractured neck.—The processus dentatus of the second vertebra is tied to the skull by a ligament, and kept close to the fore-part of the first vertebra by another in that vertebra, that it may not bruise the spinal marrow; and when either this ligament or process is broken, it is styled a broken neck, whose consequence is sudden death.

Fracture of the ribs.—When the ribs are broken, their ends recede from each other; but when they project outward, no considerable danger ensues. If they press inward they produce an uneasy pricking, inflammation, cough, fever, an abscess, or spitting of blood. The cure is generally completed by applying an exact uniform circular compressive bandage, if neither inflammation nor swelling forbid: if these symptoms attend, they must be reduced by bleeding, &c.; then the bandage and a cooling diet will succeed. See Bell's Surgery, vol. vi. p. 63. White's Surgery, p. 140.

Fracture of the skull.—When, from an injury done to the head by external violence, a loss of speech and of sense, a lethargy, or convulsions follow, no certain conclusions can be made from these symptoms, as they may be owing to extravasation or concussion as well as to fracture. If, however, upon making an incision on the part, the pericranium is found loose, a fracture has most probably taken place. In examining for a fracture, care is required to distinguish it from a suture, particularly the uncommon ones, as those about the ossa triquetra; but if, on scalping, we find the pericranium firmly adhering to any part that resembles a fracture, we may be assured that it is a suture. If, when the head is shaved, you can feel the pericranium under your finger to be loose, a fracture has clearly occurred.

When a fracture happens on the skull, the trepan is immediately used by some surgeons, with a view to obviate or prevent the effects of so great a degree of violence; but it is forbidden by the best practitioners, except a part of the skull is depressed. Celsus advises us not to proceed to an operation before the approach of unfavourable symptoms; and Ruysch adds, that "when the symptoms are not augmented, we are not to proceed to incision and perforation; but, after bleeding, we are to attempt the cure by repeated application of warm cephalic fomentations." The advice and practice of Mr. Bromfield, when a concussion of the brain happens, are of the same nature. See *Concussio*. White's Surgery, p. 211.

A fractured leg.—In the leg the tibia is generally fractured near its lower extremity, where it is weakest; and often, when the tibia is broken, the fibula is also fractured at its upper extremity. When there is a dislocation of the malleolus internus, the fibula is commonly fractured, and has occasioned it.

A fractured fibula seldom gives any uneasiness, or hinders the patient from walking; but it may be discovered by taking hold of the leg under the calf with one hand, and with the other moving the foot; for the hand which holds the leg will distinguish the fracture. Mr. Pott thinks that, in this case, a tight bandage upon the fractured part is not to be admitted; but that, if it is applied to the two extremities of the leg, the broken end will be brought into contact, and a cure will be effected.

When the tibia is fractured, lay the patient on the injured side, on a flat surface, and raise the knee of the fractured limb towards the abdomen, at the same time bending the joint; thus the extensor muscles of the foot are relaxed, and the extension required for the reduction will be performed with ease. Having replaced the fractured bone, apply a long splint padded with tow to the fibula, and another on the inside of the leg, over part of the tibia, and secure them with straps. The patient may lie on the injured side during the cure,

and thus a cradle or fracture box will be needless; the knee may also continue in the same posture as that in which the fracture was reduced.

If the tibia is fractured at its lower end by a gun shot, although the part above is apparently unhurt, the patient will lose his life unless the limb be taken off above the knee. Though if any other cause had produced a similar fracture, the operation below the knee would have succeeded. Bell's Surgery, vol. vi. p. 121. White's Surgery, p. 149.

Fracture of the cubit.—The cubit hath two bones, viz. the radius and ulna. Fractures in these are discovered by the sight, touch, and ear: by the touch and sight, if the hand of the affected cubit be moved inward and outward, though a fractured ulna, from its inability to support the joint, will be discovered sooner than that of the radius: the ear discovers a grating noise if the elbow be held steady, and the hand moved inward and outward.

If the radius is to be reduced, and the fragments have receded towards the ulna, an assistant should stretch the arm, and the surgeon should press down the patient's hand towards the ulna, until the depressed part is elevated. The arm on each side must then be compressed with the palms of the hands, so as to restore the compressed muscle between the ulna and radius, and the fragments of the radius to their natural position. A compress and strong pasteboard upon the fore part of the arm, over the quadratus muscle, will prevent it from drawing the fractured bone toward the sound one. The circular bandage must be applied, and the arm suspended in a sling, with the hand in a prone situation.

If the ulna is fractured, the same directions should be followed: remembering to turn the hand towards the radius, until the depressed part of the ulna has recovered its former position.

If both these bones are broken, we must still proceed as before. Mr. Pott observes, in this case, that it is necessary to put the longitudinal compresses as nearly as possible between the bones, in order to prevent the callus uniting them, which would hinder the rotatory motion of the arm.

It often happens in fractures of this part, that, notwithstanding every precaution, a stiff joint follows; therefore, though, in this particular instance, and in fractures of the patella, keeping the whole limb straight relaxes the particular muscles of the bones, yet if a stiff joint is apprehended, as soon as the benefits from relaxation have ceased, the limb should be gently bent; for a stiff bent cubit is much more useful than a straight one. See London Medical Journal, vol. i. p. 356; Edinburgh Medical Commentaries, vol. ix. p. 582; White's Surgery, b. iv.; Bell's Surgery, vol. vi. p. 84.

A fractured finger.—When the contusion of the hand or fingers is very considerable, amputation is most advisable; but if the part can be saved, the fractured bone must be properly placed, the fragments reduced, and the whole confined with a narrow fillet to the next finger. Begin the bandage about the wrist, carry it over the back of the hand to the finger; and, if more fingers than one are fractured, carry it round each separately, and then round them all: put a ball into the hand, and bind it tight to the fingers; continue the roller back to the wrist, and place the hand in a sling. Bell's Surgery, vol. vi. p. 93.; White's Surgery, p. 145

A fracture of the thigh.—Hippocrates justly observes, that when either the bone of the humerus or of the thigh breaks inwardly, the symptoms are more dangerous than when the same happens outwardly, because the vessels and nerves are lodged in the inner parts.

When the thigh is fractured in its middle or lower part, it may be reduced by the hand; but when the accident happens on the upper part, greater force is required. Wherever the seat of the fracture is, the position of the patient, and of the limb to be reduced, should be ordered as in the case of a fractured leg: When a due extension is made, and the ends of the fractured bone replaced, splints, properly padded with tow, must be secured; and if Gooch's machine for fractures of the thigh bone is used, patience only will be further necessary. If this machine is not to be procured, the position proposed, when the leg is fractured, may be trusted, and particularly when the neck of the thigh bone is the seat of the disorder.

When a fracture of the thigh is complicated with a wound, it is dangerous, and sometimes incurable. When near the joint it is usually fatal, as the large blood vessels are frequently lacerated. The danger is not much less if the wound is on the back part of the thigh, because of the difficulty in dressing it. If the hæmorrhage can be restrained by using the tourniquet, and taking up the wounded vessel, the fracture may be reduced; but if the bone is much injured, and the hæmorrhage violent, amputation is usually most eligible.

A fracture of the neck of the thigh bone is sometimes mistaken for luxation; but it is more easy to break than to luxate this bone, and fractures in the neck are more frequent than in its other parts. A fracture of this kind is reduced and retained with more difficulty than in the body, and a lameness usually follows the reunion. The oblique direction of the neck, with the number and strength of the muscles, occasion these difficulties.

When this fracture happens, according to Gooch, the thigh and knee are turned outwards; the limb is much shortened, and considerably shrunk; pain is felt in the course of the sartorius muscle, which, from its origin and insertion, must be greatly stretched, often causing pain on the inside just below the knee; and a crepitus is observed when the patient moves his limb. When these symptoms appear, the limb being gently but steadily extended, until the fractured limb appears as long as the sound one, let the patient be laid in the posture recommended when the leg is the part thus affected, and let bleeding be employed to prevent or remove inflammation. If Gooch's extending machine could be obtained, its use would be the most eligible method for preventing future inconveniences. Bell's Surgery, vol. vi. p. 95; White's Surgery, p. 146.

A fractured humerus.—If this bone is fractured in the middle, no great difficulty attends; but if near the superior and anterior head, both pain and danger follow. To reduce this fracture, place the patient in a chair; his elbow being bent, let an assistant steadily grasp the fractured bone at its lower end, while another assistant does the same a little below the shoulder; then the arm being extended gently, the operator takes the fractured part in his hand; and as soon as the extension is suffi-

cient, the bone being replaced, he applies the bandage, and confines it by hanging the fore arm in a sling.

It sometimes happens that when the case is an oblique fracture, the sharp end of the bone is so entangled in the adjacent muscles as to prevent a reunion; but if an incision is made upon them, and the point sawed off, they are easily replaced and readily unite. See Medical Museum, vol. ii. p. 404; Bell's Surgery, vol. vi. p. 79; White's Surgery, p. 143.

A fractured os innominatum.—In this case there is great danger, especially if the patient vomits a brown or bloody matter. In reducing it, the patient must lie on the sound side; the fractured parts must be restored by the surgeon's hands alone; then compresses, dipped in rectified spirit of wine, must be secured by means of the spica bandage. See White's Surgery, p. 143.

A fractured jaw.—When fractures of the upper jaw stretch towards the eyes, the consequent inflammation is often dangerous; and when they penetrate the antrum, they are generally tedious, and occasion great deformity. Replace the fractured bones with the fingers when there is no wound; or with forceps or a narrow scapula, when the parts are laid open; and a piece of adhesive plaster best retains the dressings. Bleeding, with an antiphlogistic regimen, must be advised to obviate inflammation of the eye and contiguous parts, and the reunion of fractured parts must be left to nature.

When the lower jaw is fractured, and its situation is ascertained, the bones must be carefully replaced; which is done by securing the patient's head, and pressing the fingers of one hand upon the inside of the jaw, while the other hand is employed externally in guarding against any perceptible inequality of the bone. If a tooth is seated in the course of the fracture, it must be immediately extracted; but if a tooth, not seated in the course of the fracture, is forced out of its socket, it may be replaced, and fixed by tying it to the contiguous firm teeth; the fractured bones must then be retained in a proper situation till they are firmly reunited, by means of a compress and bandage of soft old linen or cotton. The parts being kept firm by an assistant, a thick compress should be laid over the chin, and extended from ear to ear along each jaw; and, over the whole, a four-headed roller applied. Liquid diet is necessary until the cure is performed. See Bell's Surgery, vol. vi. p. 52, 58; White's Surgery, p. 137.

A fractured metacarpus.—An assistant may extend the fractured hand upon a smooth table, while the surgeon, with his fingers, endeavours to replace the fragments. White's Surgery, p. 145.

A fracture of the nose.—Both the bones and the cartilages are liable to be broken. If the bones are broken, the nose appears flat where the fracture is; but if the cartilage has suffered, the nose leans to one side. If the injury is considerable, the cure will be incomplete; and from the vicinity of this organ to the brain, the danger is considerable: an œzæna, a caries, or a polypus, may be the consequence. Fix the patient in a reclining posture, and elevate the depressed parts of the nose with a quill, replacing them in their proper order with the fore-finger and thumb of your other hand: to prevent their collapsing, fill the nostril with lint, or introduce a canula: if there is no wound, a plaster will secure the whole; but if there is a wound it must be treated in the

usual way. If a splinter is so situated as to be reunited with difficulty, it may be removed. When the bones are reduced, they do not easily separate. Mr. Bell thinks, that any very loose portion of bone should be removed immediately, whether it be raised up or forced into the nostril; but whatever adheres to the remaining portion of bone, with firmness, should be replaced. See Bell's Surgery, vol. vi. p. 49.; White's Surgery, p. 137.

A fractured knee pan.—When a small fragment of the fractured patella is drawn upwards, if the patient is fat, it is not very easy to discover the accident. In examining to decide whether the patella is broken, the knee must not be bent, because the fragments are thus separated further from each other, and occasion unnecessary pain. This bone is generally broken transversely; the lower part remains fixed to the knee, but the upper is drawn by the muscles on the fore part of the thigh. When the case is discovered, the patient must be laid on his back, the leg extended, and the muscles above the fractured part gently pressed downwards, until the fragments of the bones approach within an inch of each other; in this situation they must be retained by a compress and bandage. The fractured parts should never be brought close together, for a stiff joint might in that way be occasioned.

Sometimes the ligament which secures the knee pan to the tibia is broken, and this case is mistaken for a fracture of the knee pan: the mistake is not of much consequence, as the method of cure is the same. See Warner's Cases of Surgery; Medical Museum, vol. iii. p. 349, &c.; Bell's Surgery, vol. vi. p. 111; White's Surgery, p. 147.

Fracture in the foot.—Fractures in the tarsus, metatarsus, and toes, are generally accompanied with wounds, from the contusion of the nerves, tendons, ligaments, and membranes. They are cured in the same manner as those of the carpus, metacarpus, and fingers. Fractures in this part, as well as in the hand, and leg near the ankle, especially when the malleolus recedes from the principal bone, are seldom so completely cured as to leave the limb free from some inconvenience. Bell's Surgery, vol. vi. p. 130.

Fracture of the os sacrum and os coccyx—is discovered by the pain perceived in the part, and by the touch. The fragment must be reduced by the fingers; but if depressed inwardly, the fore finger must be introduced into the rectum, and the depressed part replaced. The T bandage should be then applied over a proper compress. The patient must keep his bed for two or three weeks; and when he turns from one side to the other, be cautious not to turn on his back: when he rises, the properest seat will be a chaise percée. See Bell's Surgery, vol. vi. p. 74; White's Surgery, p. 143.

Fracture of the scapula.—If the acromion be broken, it is easily reduced with the fingers, if the os humeri is raised a little upwards; but it is with such difficulty retained, that the arm can seldom be afterwards lifted freely: after the reduction, a compress must be put on it, and a ball under the arm pit: after the bandage is applied, the arm must be supported by a sling.

If the neck of the scapula, which is below the acromion, or the acetabulum, be broken, the accident is not easily discovered; but a stiffness of the joint, inflammation, abscess, or other bad symptoms, follow.

All other fractures of this bone are less hazardous;

and to reduce them, an assistant should extend the arm forward, whilst the surgeon is employed in restoring the fragments with his hands, laying on it compresses, with pasteboard splints, and securing all with the fascia stellata, or quadriga. See Bell's Surgery, vol. vi. p. 76; White's Surgery, p. 140.

A fractured sternum.—After a depression or a fracture, the part is in pain; and the accident is known by the bone grating, if moved by the fingers, and by its moving in consequence of a little pressure against it; though the proper indication is a manifest sinus or inequality in the part.

From the irritation produced by the fracture, and in part by the violence which occasioned it, pains in the breast, difficulty of breathing, violent cough, hæmoptoe, extravasations of blood within the mediastinum, with other dangerous symptoms, follow. To reduce it, the patient must lie on his back over some hard pillows, that his shoulders may be depressed, and the breast elevated; the operator must then press forcibly, to extend the ribs, and push the sternum forward. If this fails, a crucial incision must be made into the skin, and the depressed part of the sternum elevated with a terebra, gently screwed into the part.

After the reduction, the napkin and scapulary may be applied, to keep the thorax firm.

Mr. Bell, in the sixth volume of his Surgery, page 67, observed, that in some cases it is fractured without being displaced; in others it is not only broken, but at the same time forced in upon the pleura. When, therefore, the pain, cough, oppressed breathing, and other symptoms, do not yield to blood letting and other parts of an antiphlogistic course, an incision should be made upon the injured part, of a sufficient length to admit of a free examination of the bone; and the depressed piece may be raised either with a common scalpel, or a levator, if there be an opening that will admit an instrument. When this is not practicable, an opening may be made for this purpose with the trepan. If the operation be performed with caution, the bone may be raised with safety; and the sore must then be treated in the usual way. See White's Surgery, p. 139.

Fractures of the vertebræ.—When any of the vertebræ are fractured without affecting the spinal marrow, the posterior apophyses, or acute tubercles, are only injured, and these fractures are not dangerous. The parts may be replaced with the fingers, and on each side of the spina dorsi narrow compresses moistened with spirit of wine should be applied, secured with pasteboard splints, the napkin, and scapulary.

Fractures in these parts are easily known by the pain, and on slightly touching them.

If the transverse apophyses which tend towards the cavity of the thorax are broken, the heads of the ribs inserted into them will likewise be fractured, and the case is dangerous.

When the body of a vertebra is broken, the spinal marrow is injured, and the parts below the fracture are motionless, and death soon follows. In this case, not to seem either negligent or ignorant, the injured part must be laid bare, the fragments which press the medulla elevated, and, if loose, extracted: the wound may then be cleaned and dressed with warm stimulating applications. See Boerhaave's Aphorisms; Petit on the Diseases of the Bones; Aitkin's Treatise on Frac-

tures; Pott's General Remarks on Fractures; and Kirkland's Observations on Pott's Remarks; for machines to be used after the reduction of fractures, see Gooch's Cases and Remarks; Bell's Surgery, vol. vi. p. 71; White's Surgery, p. 142.

FRA'NUM, (from *fræno*, to curb). See LIGAMEN-
TUM ANNULARE, LINGUA and PENIS.

FRA'GA, (from *fragro*, to smell sweet). The STRAWBERRY. (See ARBUTUS.) *Fragaria vesca* Lin. Sp. Pl. 708. The common wood strawberry, the most agreeable kind, flowers in May, and the fruit ripens in June. A decoction of the whole plant is used against the jaundice.

FRAGARO'DES, (from *fragura*, a strawberry, and *ειδος*, likeness). BAREN STRAWBERRIES. See ARBUTUS.

FRAGI'LITAS O'SSIUM, (from *frango*, to break,) *friabilitas ossium*, has been supposed to consist in too great redundancy of the earthy principle in the sound habit. In the diseased, the scurvy, lues venerea, and scrofula, may occasion it. Mr. Sharp attributes it to a defect of the oil; but the real cause of fragility from disease is a deficiency of the earth, and the bones are broken with little or no pain. The *fragile vitreum* of pathologists is supposed to be owing to cold. See MORBI SOLIDI SIMPLICIS.

FRAMBŒ'SIA. See YAWS.

FRA'NCOLIN. See ATTAGEN.

FRA'NGULA, (from *frango*, to break; so called from the brittleness of its branches). See ALNUS NI-
GRA.

FRAXINE'LLA, (from *fraxinus*, the ash). See DICTAMNUS ALBUS.

FRAXINUS, (from *fragore*, from the noise its keys make when shook by the wind,) *bumelia*. The ASH-TREE; *fraxinus excelsior* Lin. Sp. Pl. 1509, is a tall tree, common in woods and hedges. Its bark whitish; the seeds oblong, reddish, or brownish coloured, shaped somewhat like a bird's tongue, whence they are called *lingua avis*, and *orintho-glossum*.

The fresh bark is bitterish and astringent, but loses these qualities in drying. A drachm of this bark is diuretic, and the watery extract hath the same effect. The middle bark hath been used in intermitting fevers, when assisted by alkaline salts.

The seeds are diuretic and healing, in the dose of a drachm. Raii Hist. Lewis's Materia Medica.

FRAXINUS O'RNŪS. The FLOWERING ASH. *Manifera arbor* Lin. Sp. Pl. 1510; though later authors have found the manna to be the production of another species not noticed by Linnæus, the *f. rotundifolia*. See MANNA.

FRE'NA. See ALVEOLUS.

FRIABILITAS O'SSIUM, (from *frio*, to crumble). See FRAGILITAS.

FRI'CTA. See COLOPHONIA.

FRI'CTIO, (from *frico*, to rub). RUBBING. Friction of the body, if duly continued and repeated, promotes absorption and perspiration, quickens the circulation, particularly through the finer capillaries. It contributes not only to convey medicines into the body, but also to their advantages when introduced. This remedy is best used when the primæ viæ are most empty, and the chylopoietic organs too languid, and should in that case be steadily applied over the whole abdomen. Gentle

friction with oily substances relaxes; but strong friction with rough dry cloths is a powerful tonic. It has been considered particularly useful in ascites, and many other cases where the action of the absorbent system is to be promoted. When the brush is employed, the vessels are only slightly stimulated; but the most effectual means of applying it is by rough cloths, flannels, or woollen gloves. As much pressure should be used as the parts can bear without pain, and it is often advantageous that the patient should be also the operator.

FRI'ESEL. See MILIARIS FEBRIS.

FRIGIDA'RĪUM, (from *frigidus*, cold). A vessel in the baths for holding cold water. It sometimes means the cold bath.

FRIGERA'RIA. See PUTRIDA FEBRIS.

FRI'GUS, (from *frigeo*, to be cold). COLD. In Vogel's Nosology it signifies the coldness of the feet and hands. Heat and cold are the names of certain sensations in our bodies, and depend on the substances which produce them having a less or a greater affinity for heat than the bodies themselves. See COLD.

FRI'TTA. FRITT; *ammonitrum*, is a mass of salt and ashes concreted with the sand in making glass.

FROND. A twig of a tree with its leaves; Linnæus applies this term to the peculiar leafing of palms and ferns. Martyn says it was anciently written *fruns*, from *βρω*, *pollulo*, to germinate or bud.

FRONDI'PORA. See ESCHARA.

FRONS, (from *φρονος*, *thought*, as the supposed seat of thought). The FOREHEAD is that part above the eyes destitute of hair, extending from one temple to the other; but in ancient authors it sometimes means the whole countenance. In botany it means a leaf or branch, from *fero*, to bear.

FRONTA'LE, (from *frons*, the forehead). The name of a topical medicine applied to the forehead; *anacolema* (see CATAPLASMA): it often means also a linen bag, in which cephalic ingredients are contained to be applied to the forehead. See EPITHEMA.

FRONTA'LIS, MU'SCULUS VE'RUS. See CORRUGATOR COITERII.

FRONTA'LIS NE'RVUS. The fifth pair of nerves from the brain, sends off its first branch, called *orbitarius crani ramus superior*, which is subdivided into three: the first is the frontal, which spreads on the upper part of the orbit of the eye, to the fat which surrounds the globe of the eye, the musculus elevator palpebræ, &c.

FRONTA'LIS SI'NUS. The FRONTAL SINUS. There are two of these formed of the separated laminæ of the os frontis; placed above the orbits, on each side the top of the nose: they are covered with the same membrane which lines the nostrils, and open into them; but are occasionally wanting.

FRONTA'LIS VE'NA is a branch from the external jugular, forming a vein in the forehead, called by the ancients *fræparata vena*.

FRONTIS, OS. The BONE OF THE FOREHEAD; *cornale os*, *inverecundum*, *motophon*. The external surface of this bone is smooth at its upper convex part, but below several cavities and processes are observed. At each angle of the orbit the bone juts out to form two internal and two external processes. The ridge which makes the supercilium is called the superciliary process. The lower part of the forehead, where the hair of the eye brows grows, is called *ophrys*. The nasal process

is situated between the two internal angular processes; and the two orbital processes are continuations of the superciliary: between these is an aperture for the reception of the ethmoid bone. At the internal angular process is a cavity for the *caruncula lachrymalis*; at the external angular process is another for the pulley of the musculus obliquus major. The foramina are three on each side; one in each superciliary ridge, through which a nerve, vein, and artery pass to the integuments of the forehead. Near the middle of the internal side of the orbit, in the transverse suture, or near it, is a small hole, called the *internal orbital*: the orbital internus posterior is smaller, and lies about an inch deeper in the orbit. On the inside of the *os frontis* there is a ridge, which, on the upper part, is imperceptible, and grows more prominent at the bottom, where there is a foramen cæcum; to this ridge the falx is attached. The frontal sinus is placed over the orbits, and is divided by the septum just described. This bone is of mean thickness, between that of the *os occipitis* and of the parietal bones; but at the orbital process, from the pressure of the brain and the globe of the eye, it is almost transparent. It will be obvious that the trepan cannot be applied over the sinuses to reach the brain.

FRUCTIFICA'TIO, (from *fructifico*, to make fruit-ful). FRUCTIFICATION, or FRUITING, consists in the flower and fruit; and there is no fructification without anther, stigma, and seed. When perfect, it consists of seven parts.—1. Calyx—2. Corolla—3. Stamen—4. Pistil—5. Pericarp—6. Seed—7. Receptacle.—Of these, the four first belong to the flower; the two next to the fruit; and the last is common to both. The pedicle of the flower or blossom is the stem of the fruit, and its fibres are expanded through the whole bulk. The epidermis forms the calyx, the next layer of the bark the liber, the wood the antheræ, and the medulla the stigma. All previously exist; and in no instance is there any new formation: all is evolution only.

FRU'CTUS, (from *fruor*, to use, or from *feri*, Heb.). FRUIT; *carpos*. It is properly the part of a plant wherein the seed is contained, but in general it is any seed or grain covered with a pulp or shell, or uncovered; but it is more strictly styled fruit when there is a pulpy covering. For the nutritious properties of fruits, see ALIMENT. The chemists call metals the fruits of the earth.

FRU'CTUS UMBILICA'TUS. UMBILICATED FRUIT is that on which the flower grows. The flower usually forms a cavity, called *umbilicus*, or *navel*, as in the medlar, hip, &c.

FRUMENTA'CEUS, (from *frumentum*, wheat). A term applied to all such plants as resemble wheat in their fruit, leaves or ears.

FRUME'NTUM, (quasi *frugamentum*, from *fruges*, fruit). CORN. It is spontaneous in many climates, but industry has meliorated it in all. It is a species of grass in its primitive state, whose seed is improved by culture. A name also of wheat. See TRITICUM.

FRUME'NTUM CORRUPTUM. See BRASIUM.

FRUME'NTUM I'NDICUM, FRUME'NTUM TURCICUM. See MAYS.

FRUME'NTUM SARACE'NICUM. See FAGOPYRUM.

FRUSTA'NEUS, (from *frustra*, in vain). Botanically applied, it means having the parts of fructification neutral or infertile.

FRU'TEX, (*à ferendo fructum*, from bearing fruit). A SHRUB. It is a plant with many woody perennial

trunks, such as roses, or seringas. Linnæus makes the distinction of a shrub from a tree to consist in its having no buds, though trees have often no buds in hot climates; and he acknowledges that nature has placed no limits between them. The word is generally used by gardeners for all woody plants of low growth.

FRU'TEX BA'CCIFER BRASILIE'NSIS. See CAAGHI-YUYO.

FRU'TEX I'NDICUS BA'CCIFER. See BELILIA.

FRU'TEX I'NDICUS SPINO'SUS. See CARA SCHULLI.

FRU'TEX ODORA'TUS SEPTENTRIONA'LIUM. See MYRTUS BRABANTICA.

FRU'TEX PAVONI'NUS. See POINCIANA.

FRU'TEX TERRIBILIS. See ALYPIA.

FRUTICO'SUS, (from *frutex*, a shrub). FRUTICOSE. Plants which are of a woody substance.

FUCOI'DES, (from *fucus*, and *ειδος*, likeness). A species of an aquatic plant, of a middle nature betwixt conserva and fucus. It is often finely divided, of a more tender substance than the fucus, and not distinguished by nodes and joints like the conserva or corallina.

FU'CUS, (from *φυκος*, from *fuka*, Hebrew, *antimony*; so called because, like antimony, it was used in painting the cheeks). A species of plant growing in the sea, whose leaves and stalks are of various figures. It is generally of a viscid and coriaceous substance, and furnished with vesicles on both sides, which admit air being separated to assist its floating. Its extremities are often set with tubercles, which have been supposed to be its fructification. Those used in medicine are, 1. *Alga marina latifolia vulg.* *Fucus vesiculosus* Lin. Sp. Pl. 1626. (See QUERCUS MARINA.) 2. *Lactuca marina*; *ulva marina* Lin. Sp. Pl. 1632; which is of the same use as the alga.

FU'CUS ESCULE'NTUS. The tangle of Scotland, an edible crisp, but not a very nutritious, marine plant.

FU'CUS MARI'TIMUS. See KALI.

FU'CUS MARI'NES. See ALGA.

FU'GA DÆMO'NUM, (because it was thought to drive away evil spirits). See HYPERICUM.

FUGACI'SSIMUS, (from *fugax*, speedy). In botany it is applied to the petals, and means of very short continuance.

FULCRA'TUS, (from *fulcrum*, a prop,) PROPPED; applied botanically to a branch, descending to the ground, and supporting the stem.

FUGI'LE. EAR WAX. (See CERUMEN AURIS). An appearance in the urine like wax. (Paracelsus.) It sometimes means a bubo, at others a tumour of the parotid glands.

FULI'GO, (quasi *fumiligo*, from *fumus*, smoke,) *araxos*, *asofer*, ASUOLI, SOOT, is the shining black concrete, formed by the smoke from wood. It hath a disagreeable smell, and a pungent bitter nauseous taste: the more resinous the wood, the more bitter will be the soot. By a chemical analysis it affords a volatile alkaline salt, an empyreumatic oil, a fixed alkali, an acid formed by the decomposition of the mucilage, and a resin soluble in alcohol.

Soot yields its virtues to water, or to proof spirit, each of which dissolves about one fourth part of it; and is considered as an antispasmodic, and an emmenagogue.

FULMINA'TIO, FULMINATION, (from *fulmino*, to lighten or thunder). In chemistry it means generally explosion, when it is the same with *detonation*. But in

the depuration of the more perfect metals, when infused with lead, a bright colour succeeds a kind of sulphureous cloud before appearing in the metal during the fusion, which has this appellation. See DETONATIO.

FUMA'RIA, (from *fumus*, smoke; since, like smoke, it draws tears). FUMITORY. *Fumis terra, capnos, herba melancholifuga; fumaria officinalis* Lin. Sp. Pl. 984. COMMON PURPLE FUMITORY. It is a plant with bluish green, finely divided leaves, producing, towards the tops of the stalks, spikes of irregular purplish flowers, followed each by a single seed; annual, flowering in May and June, and delighting in shady places. The leaves have a bitter saline taste; and an extract obtained from a decoction of them is very bitter. The juice of these leaves, if dropped into the eyes, is supposed to cure dimness of sight. The plant has been supposed by physicians of the first authority to be a powerful deobstruent, particularly of the hepatic system; and it is highly commended in scorbutic and acrimonious states of the fluids; consequently in various cutaneous diseases. The juice, mixed with whey, and used as common drink, is said to prove diuretic and laxative. Dr. Cullen has found it useful in many cases where bitters are prescribed; but it is chiefly useful in clearing the skin, and he has experienced its good effects in many instances of cutaneous affections, resembling lepra. The dose is two ounces of the expressed juice twice a day: the dried root may be also given in infusion, or decoction; or the extract may be substituted; for these all retain the virtues of the fresh herb.

FUMA'RIA BULBOSA, Lin. Sp. Pl. 983, is of similar virtues, but weaker than the *f. officinalis*.

FUMA'RIA A'LBa, also called *cysticapnos Africana scandes*. AFRICAN CLIMBING BLADDER FUMITORY.

Fumaria vesicaria Lin. Pl. Sp. 985, is a climbing plant, chiefly resembling the fumitory above described, only that the fruit is an oval bladder, containing the seeds.

FUMIGA'TIO, (from *fumus*, smoke). FUMIGATION. By the subtle fumes inspired, or sometimes swallowed, much benefit or injury may be produced. The latter is evident from the palsies produced among workers in lead and quicksilver mines, and the benefits derived from impregnating the air with salutary materials. Catarrhs and catarrhus coughs are relieved by fumes received with the breath, sometimes of warm water, at others, it is said, of æther; and by the same method expectoration is assisted in asthmas: even ulcers in the lungs have, it is said, been healed by this method. The advantage of fumigations in the cure of venereal ulcers is well known, though the practice is now disused. (See INHALATIO.) But this plan has been lately revived by Mr. Abernethy, and is supposed to affect the constitution when other methods have failed, and to produce its effects in a comparatively shorter time. Lalouette's powder was supplied by precipitating the oxide of mercury from calomel by means of ammonia, and it is sprinkled on a hot iron, while the fumes are confined by the patient being placed in a box. Partial mercurial fumigations are used also in white swellings of the knee, and swellings of the breast.

FUMIGA'TIO NITROSA. See CONTAGION.

FU'MUS TE'RRÆ. See FUMARIA.

FU'NCTIO, (from *fungor*, to perform). See ACTIO.

We shall add professor Richerand's new classification of the functions. It is elegant, comprehensive, and complete.

THE PLAN OF A NEW CLASSIFICATION OF THE FUNCTIONS OF LIFE.

CLASS I.—FUNCTIONS THAT SERVE FOR THE PRESERVATION OF THE INDIVIDUAL.—(Individual life.)

ORDER I.
Functions which assimilate the aliment by which the body is nourished.
(Assimilating, internal, or digestive functions.)

GENUS I.—DIGESTION
Extracts the nutritive part.

GENUS II.—ABSORPTION
Carries it into the mass of humours.

GENUS III.—CIRCULATION
Propels it towards the organs.

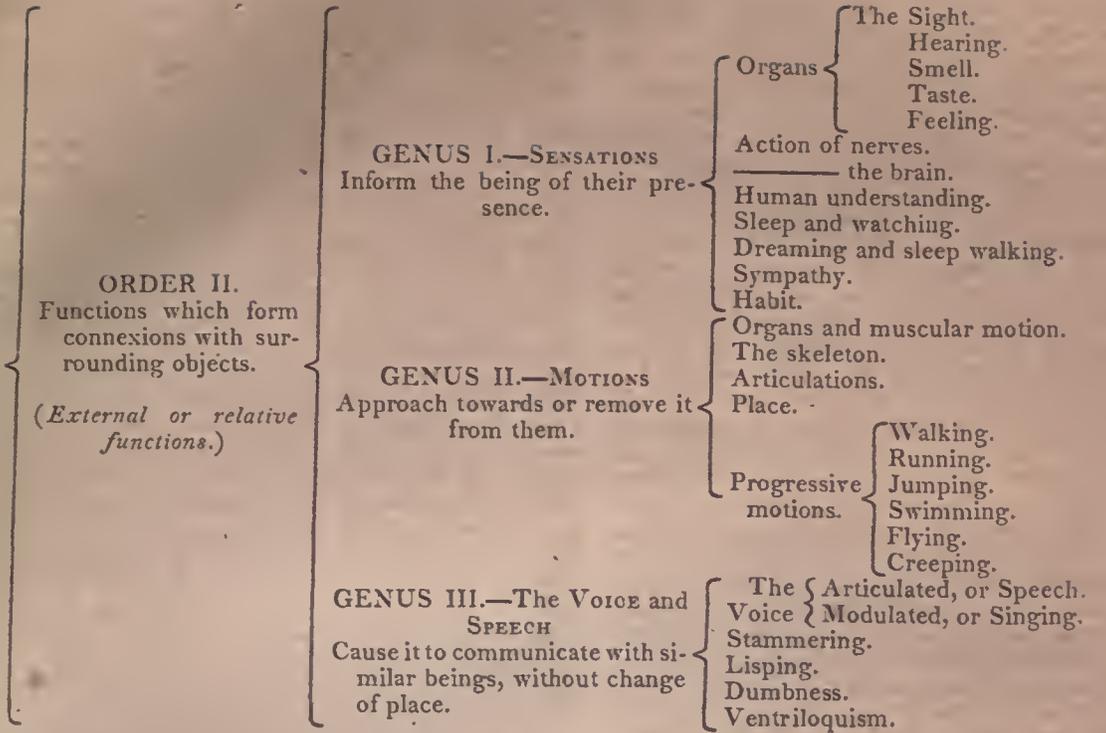

GENUS IV.—RESPIRATION
Combines it with atmospheric oxygen.

GENUS V.—SECRETION
Causes it to pass through several modifications.

GENUS VI.—NUTRITION
Applies it to organs, to which it is to supply growth, and restore their loss.

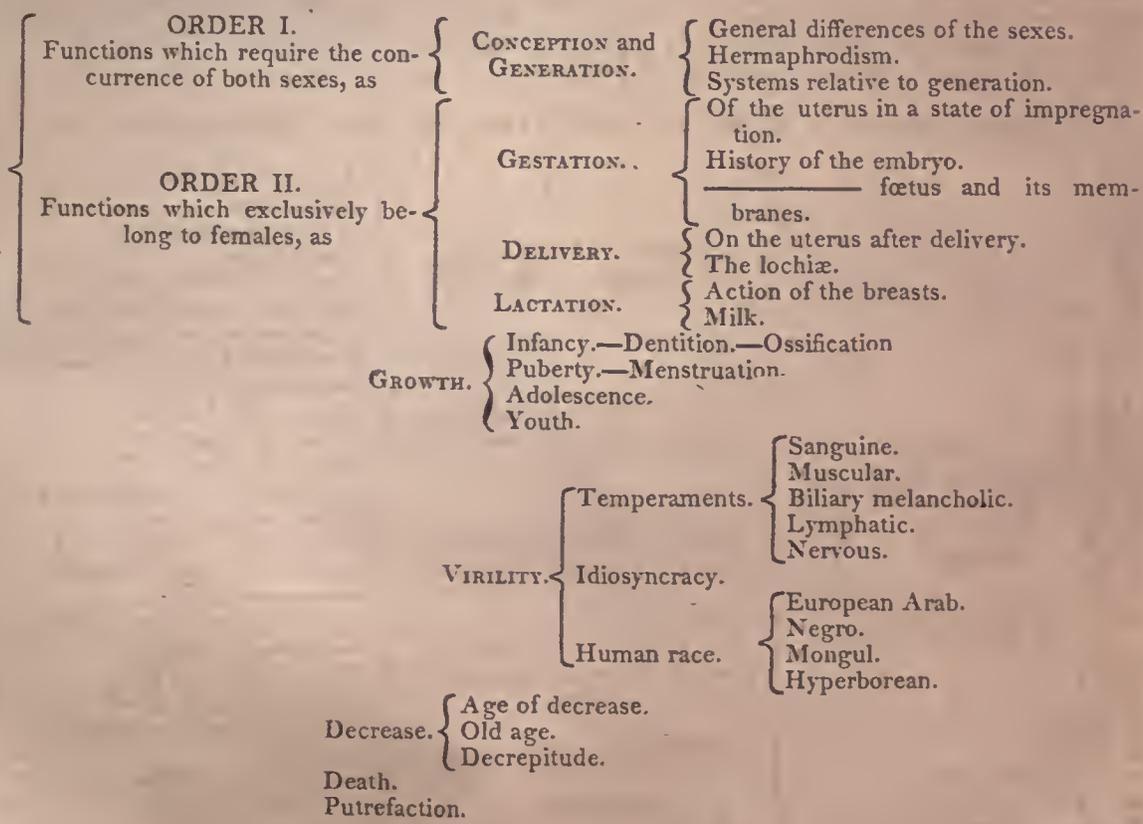

- Reception of the food.
- Mastication.
- Solution by the saliva.
- Deglutition.
- Digestion in the stomach.
- _____ duodenum.
- _____ intestines.
- Excretion of the fæces and of the urine.
- Inhalation of chyle.
- _____ lymph.
- Action of vessels.
- _____ glands.
- _____ the thoracic duct.
- Action of the heart.
- _____ arteries.
- _____ capillary vessels.
- _____ veins.
- Action of the parietes of the thorax.
- _____ lungs.
- Alteration of the air.
- _____ in the blood.
- Disengagement of animal heat.
- Exhalation.
- Secretion by follicles.
- _____ glands.
- Different in every part according to the peculiar composition of each.

(CLASS I. Continued.)

CLASS II.

FUNCTIONS THAT SERVE FOR THE PRESERVATION OF THE SPECIES.—(*Life of the species.*)

The splendid work of M. Vicq d'Azyr on the Brain furnishes us with the following table of the FUNCTIONS, or the *proper characters of living bodies*. These are, DIGESTION, NUTRITION, CIRCULATION, RESPIRATION, SECRETIONS, OSSIFICATION, GENERATION, IRRITABILITY, and SENSIBILITY. Every body in which one or several of these functions are observed must be regarded as an organized or living body.

I. *Digestion*. Which have one or many stomachs distinct from the œsophagus and intestinal canal: MAN, QUADRUPEDS, CETACEA, BIRDS, and CRUSTACEA.

LIVING BODIES,

Whose stomachs are distinguished from the œsophagus and intestinal canal only by some enlargement: OVIPAROUS ANIMALS, SERPENTS, CARTILAGINOUS and PROPER FISH.

Who have only an alimentary tube: INSECTS, WORMS, ZOOPHYTES.

Who have neither stomach nor intestinal canal: PLANTS.

II. *Nutrition*. Whose nutritious juices are absorbed by the vessels opening into the external cavities; ANIMALS of EVERY KIND.

LIVING BODIES,

Whose nutritious juices are absorbed by vessels opening externally: PLANTS.

III. *Circulation*. Having blood, blood vessels, and a heart with two ventricles and two auricles; MAN, QUADRUPEDS, CETACEA, and BIRDS.

LIVING BODIES,

A single ventricle, internally divided into several cavities and two auricles: OVIPAROUS QUADRUPEDS and SERPENTS.

A single ventricle, and auricle: CARTILAGINOUS and OTHER FISH.

Whose heart is formed by a long convoluted contractile vessel containing a white fluid: CRUSTACEA, INSECTS, and WORMS. In some crustacea there are traces of a heart.

Who have no heart, but vessels filled with fluids of different kinds: ZOOPHYTES and PLANTS.

IV. *Respiration*. Who breathe by free unconnected spongy lungs: MAN, QUADRUPEDS, CETACEA.

LIVING BODIES,

Who breathe by free cellular muscular lungs: OVIPAROUS QUADRUPEDS and SERPENTS.

By lungs adhering to the ribs provided with appendices: BIRDS.

By gills of different forms: FISH and CRUSTACEA.

By holes placed on different rings: INSECTS and EARTH WORMS.

By a trachea and external fringes: AQUATIC WORMS.

By tracheæ: PLANTS.

In which neither holes nor tracheæ are discernible: POLYPI.

V. *Secretion*. This takes place in different forms or degrees in every living body.

VI. *Ossification*. Which have an internal bony skeleton: MAN, QUADRUPEDS, CETACEA, BIRDS, OVIPAROUS QUADRUPEDS, and FISH.

LIVING BODIES,

An internal cartilaginous one: CARTILAGINOUS FISH.

An external horny: PERFECT INSECTS and LITHOPHYTES.

Calcareous: CRUSTACEA, SHELL FISH, the greater number of MADREPORES, ZOOPHYTES.

Woody: PLANTS.

Which have no skeleton: INSECTS in their larva state, WORMS, POLYPI.

VII. *Generation*. Viviparous: MAN, QUADRUPEDS, CETACEA.

LIVING BODIES,

Oviparous, whether hatched internally or without the body: BIRDS, OVIPAROUS QUADRUPEDS, CARTILAGINOUS and other FISH, SERPENTS, INSECTS, CRUSTACEA, WORMS, PLANTS.

VIII. *Irritability*. Wholly muscular or contractile: the greater number of the larvæ of INSECTS, WORMS, POLYPI.

LIVING BODIES,

Whose muscles cover their skeleton: MAN, QUADRUPEDS, BIRDS, CETACEA, OVIPAROUS QUADRUPEDS, FISH, SERPENTS.

Whose muscles are covered by their skeleton: PERFECT INSECTS and CRUSTACEA.

Who have some contractile parts, but no spontaneous motions: PLANTS.

IX. *Sensibility*. Who have nerves, and a brain distinct from their spinal marrow; ALL ANIMALS, except those in the following sections.

LIVING BODIES,

Who have nerves and a brain scarcely distinct from their spinal marrow: INSECTS, CRUSTACEA, WORMS.

Without discovered nerves, brain, or spinal marrow: ZOOPHYTES, PLANTS.

See ANIMAL.

-FUNGUS, (*σπογγος*, *sponge*; from their spongy contexture). TOADSTOOL, *besacher*; is the lowest, and a very imperfect vegetable genus, having neither visible seeds, flowers, leaf, nor the structure of a plant. Most of them spring up from, and are soon dissolved into, mucous matter. See Ray's Synopsis, and AMANITA.

FUNGUS, in surgery, is a spongy excrescence, which arises in wounds and ulcers, commonly called, though often improperly, *proud flesh*. In general, dry lint is the best application. A spongy lax flesh, rising from the bottom of ulcers, differs much from the fungus in healing wounds, and often requires the knife, or a caustic: the former is in one mass, but the fungus in healing wounds in many little protuberances. When this ill-conditioned spongy flesh arises, it is of very little use to attempt its destruction before the general habit is improved; and when this is effected, dry lint, or other gentle means, will be generally sufficient. The fungus

over a carious bone cannot be removed before the caries is stopped, and the exfoliation completed: the fungus then disappears spontaneously.

If fungous excrescences arise from the brain after trepanning, they may be cut away with a knife, or suppressed with lint dipped in rectified spirit of wine, and gentle pressure.

If the tumour appear to increase internally, a circumstance known by symptoms of compression on the brain, it has been sometimes advised to enlarge the opening of the bone; a precarious measure, often attended with dangerous hæmorrhage. Pressure in this case is inadmissible; but Mr. Abernethy suggests the application of vegetable astringents. Some benefit has, it is said, resulted from sprinkling these tumours with equal parts of myrrh and lapis calaminaris.

Fungus is also the name of a tubercle about the anus, occasioned and cured like a condyloma.

White swellings are called *fungi* by some authors. In Vogel's Nosology it signifies a soft œdematous tumour of the joints. Dr. Gottlieb Richter observes, that in consequence of external bruises, sometimes after catching cold, and often spontaneously, a round, pretty regularly circumscribed swelling arises round the patella: it is not painful, and a fluctuation is obvious. It sometimes occupies both sides of the patella, is sometimes confined to its ligament, and frequently surrounds the whole knee pan. The patient feels no complaint, except some degree of stiffness in the motion of the knee joint. This tumour must not be opened; and he recommends the following plaster, taking also tartar emetic in small doses, and rubbing the knee with the volatile liniment. R. Gum. ammon. \mathfrak{z} i. solv. in aceti scillitici, q. s. ad. consistentiam unguenti tenuioris. This must be spread thick upon leather, applied over the whole knee. Similar tumours on the joints of the elbow have been observed.

FU'NGUS ALBUS ACRIS, FU'NGUS PIPERA'TUS ALBUS. See AGARICUS PIPERATUS.

FU'NGUS ARTICULI. See SPINA VENTOSA.

FU'NGUS IGNI'RIOUS and LA'RICIS. See AGARICUS and AGARICUS QUERCUS.

FU'NGUS MELITE'NSIS. *Cynomorion coccineum* Lin. Sp. Pl. 1375, supposed to be an astringent, and used in diarrhœas and dysenteries.

FU'NGUS SALICIS, *boletus suaveolens* Lin. Sp. Pl. 1646. It has at first an acid taste, and is then bitter. It has been employed in hecticis, but is now disused.

FU'NGUS HEMATODES. This singular complaint was first distinctly described by Mr. Hey, in his very excellent work, entitled "Practical Observations in Surgery." It is a bloody tumour which forms in every part of the body, painful when seated in the muscles; but producing little inconvenience when in the cellular substance. It distends the integuments; but does not, like an abscess, render them thinner. When pressed with the hands, one part will give the sensation of a deep-seated fluid; in another the tumour is hard and uneven. When the integuments burst, the appearances are sometimes those of an excoriation only; sometimes a dark, bloody mass protrudes through the aperture. Where the fungus comes into contact with the muscles, they lose their natural redness and their fibrous appearance, becoming brown, and like the adipose membrane.

When the fungus appears through the skin, it bleeds

copiously, and the hæmorrhage is frequently repeated till the patient sinks; neither the hydrargyrus nitratus ruber, the hydrargyrus muriatus, antimonium muriatum, or undiluted vitriolic acid, can repress its growth. Amputation is the only remedy; and if the tumour has begun at the lower part of a limb, and the slightest portion is left at the upper, the disease returns. It appears to be an organised, and is probably a living, parasitic animal, nourished by the vital fluid of the patient, and capable of absorbing from the subjacent vessels what is effused from its own.

FU'NGUS MA'XIMUS ROTU'NDUS PULVERULE'NTUS. See LYCOPERDON VULGARE.

FU'NGUS MEMBRANA'CEOUS, and SAMBU'CI. See AURICULÆ JUDE.

FU'NGUS, PETRÆ'US MARI'NUS. See ANDROSACE.

FU'NIS BRA'CHIL. See MEDIANA VENA.

FU'NIS vel FUNI'culus UMBILICALIS, (from its resemblance to a rope). The NAVEL-STRING. It is of very different lengths, commonly about half a yard; usually fixed near the middle of the placenta, but occasionally near its edge. It is composed of two arteries and two veins: though sometimes the vein, and at others the artery, is single. These vessels are convoluted, and surrounded by a fine net work of fibres of a gelatinous texture. The arteries are continuations of the internal iliacs or hypogastrics; the veins are formed by the union of all the branches in the placenta; they are continued into the abdomen at the navel, and so on to the vena portæ in the liver. (See FÆTUS). After the birth, the remaining parts of the arteries in the abdomen form the ligamenta umbilicalia inferiora, and the veins the falciform or suspensory ligament of the liver.

There is always a point where the funis begins, and where the integuments separate from it: it is indifferent where it is divided, as it always drops off at the same place.

If the funis be torn off from the child, so that a ligature cannot be applied, Le Motte assures us he succeeded in preventing an hæmorrhage by applying pledgets of lint, and confining them with proper compresses and bandage; but some recommend the needle and ligature. Animals stop the hæmorrhage by drawing the funis with their teeth; and, in such cases, we might imitate the practice by employing the forceps.

If the child descends to the os externum, but seems to be drawn up and down as if suspended by a rope, the funis is probably too short, or entangled: in this case some practitioners have cut it about five or six inches from the child's belly; but with a little patience it will stretch sufficiently.

FURCELLA, FU'RCULA INFE'RIOR, (a dim. of *furca*, a fork). See ENSIFORMIS.

FURCULÆ, (from *furca*, a fork). See CLAVICULÆ.

FURFUR, (from the Hebrew term *farfarah*, to break into small pieces). BRAN. Called by Cœlius Aurelianus *cantabrum leptopityron*. It is commended as excellent for removing offensive sordes from the head; and for relieving headachs, when rubbed warm on it. It has been used also as an expectorant, in decoction, or rather in infusion; and, sweetened with honey, is said to relieve violent and obstinate coughs. We have already remarked that it is almost exclusively gluten and of an animal nature, producing, by distillation, ammonia

FURFURA, (from *furfur*, bran). SCURF. Small exfoliations of the cuticle from exudation, like bran, which follow some eruptions on the skin: a new cuticle is formed underneath during the exfoliation:

FURFURA'TIO. See FURFUROSI.

FURFURES, (from *furfur*, bran). The appellation of urine, whose sediment resembles bran. It is also called *petyroides*; and is synonymous with *furfurosi*.

FURFURO'SI, (from the same). Those afflicted with a scurf on the head, which, upon combing, discharges a scaly substance like bran, sometimes called *porrigo*, and *farrea nubes*.

FURNUS. See FORNAX.

FURIO'SUS, (from *furio*, to enrage; so called from the violence of pain). See AMBULO.

FUROR UTERI'NUS, (from *furo*, to be mad, and *uterus* the womb,) *acraï*, *brachuna*, *astromania*, *arascan*, *arsatum*. Dr. Cullen calls it *nymphomania*; and places it in the class *locales*, and order *dysorexiæ*. He defines it an unrestrained desire for venereal enjoyment: but there is one species, varying only in its degree. It is a kind of madness, or an high degree of hysteria; and its immediate cause a preternatural irritability of the uterus and pudenda of women, or an unusual acrimony of the fluids in these parts.

The disease is known by the wanton behaviour of the patient: she speaks and acts with unrestrained obscenity, and, as the disorder increases, scolds, cries, and laughs, by turns. While reason is retained, she is silent and melancholy; but her eyes discover an unusual wantonness, which is soon manifested by every word and action.

In general, it is relieved by time and medicines, more often by matrimony; but it sometimes degenerates into mania.

Bleeding is sometimes useful; but the best remedy is camphor, in doses of ten to fifteen grains, with nitre, and small doses of the tinct. opii, at intervals. The cerussa acetatta has been given in doses of three to five grains; and cooling purges have been repeated in proportion to the violence of symptoms with advantage. Injections of barley water, with a small quantity of hemlock juice, have been recommended; but we know not with what success they have been employed. The regulation of the mind; avoiding improper company, either of young men, or, what is infinitely more dangerous, wanton women; is of the highest importance. See Riverius's Practice of Physic.

FUR'UNCULUS, (from *furo*, to rage; from the violence of the heat and inflammation previous to suppuration,) called *dothein*; and by Paracelsus, *chiadus*, *chioli*; a BOIL, is a phlegmonous tumour which commonly terminates in a suppuration of a peculiar kind. It is a variety of the phlogosis phlegmone (Culleni), distinguished on account of the form in which it appears. A boil is a small circumscribed inflammation, arising in

the external parts, and terminating in an acute tubercle, about the size of a pigeon's egg, attended with redness and pain, and sometimes with a violent burning heat. These inflammations cannot be discussed; but for the most part suppurate spontaneously, but slowly, and break at first on their top, or the most pointed part, when some drops of pus, as from an abscess, come out. The germ, or what is commonly called the *core*, is next seen: it is a purulent substance, but so thick and tenacious that it appears like a solid body, which may be drawn out in the shape of a cylinder, like the pitch of an elder branch, sometimes to the length of an inch. The separation of this core is usually followed by the discharge of some liquid matter, spread through the bottom of the sore. As soon as this is discharged, the pain entirely ceases, and the opening heals spontaneously: if it should not, the cure may be effected by a small quantity of Peruvian balsam.

Suppuration is the best method of removing this kind of tumour; for if repelled, it almost as certainly returns on some other part: but indeed the surgeon is seldom applied to on account of it, the common method of applying a poultice of flour and honey, sometimes a plaster of shoemaker's wax, answering every purpose. If, however, they do not come forward to suppuration, this process should be assisted by fomentations, a gum plaster, or any warm application. In other circumstances, emollient cataplasms, mixed occasionally, if the pain is violent, with extract of hemlock, or with opium, are useful. The root of the white lily is supposed to unite a stimulus with its emollient property.

These complaints are seldom attended with any danger; they are more frequently signs of a strong constitution, capable of throwing some morbid matter out of the habit. They have been considered sometimes habitual; then alterative medicines are necessary. Rosemary has been recommended: and the burdock root has been even considered as a specific. See London Medical Journal, vol. i. p. 332. Pearson's Principles of Surgery, vol. i. p. 66, &c. White's Surgery, p. 17. See ABSCESS.

FUSA'NUS, or FUSA'RIA, (from *fusus*, a spindle: because its wood is made into spindles). See EVOXYMUS.

FUSIFO'RMIS, (from *fusus*, a spindle, and *forma*, likeness). Botanically, it is applied to the root, and means tapering like a spindle.

FU'SIO, (from *fundo*, to pour out). FUSION, *diachysis*. It is the reduction of solid bodies to a state of fluidity by fire. *Fusio* and *solutio*, per ignem, mean the same; but, by fusion, we usually understand a solution or liquation of metals or minerals: by liquefaction, a solution of pinguous and concreted substances; by solution, the union of a body with a menstruum into a transparent fluid.

G.

G A L

GABIA'NUM O'LEUM. See PETROLEUM VULGARE.

GABIRE'A. See MYRRHA.

GA'BRIEN. See BEYA.

GACIRMA. See CUMANA.

GA'GEL. See MYRTUS BRABANTICA.

GALA'CTIA, and GALACTIRRHŒ'A, (from *γαλα, lac, and ρεω, fluo*). An excess or overflowing of milk.

GALA'CTINA, (from *γαλα, lac*). See LACTICINIA.

GALACTITES, a fossil employed by the ancients, sometimes as an astringent, but more frequently as a promoter of the secretion of milk, Pliny xxvii. 59. It derives its name not from its colour, but from its whiteness when triturated with water, Dioscorides lib. v. c. 150; and seems to be the same with the morochites of Pliny, *ομοροχθος* of the Egyptians, the moroxite of Karsten. The ancients discovered it in Egypt on the banks of the Nile. Abilgaard found it to contain sixty parts of lime, twenty of alumine, four of magnesia, and four of carbonic acid. It differs from the dolomie in having a less proportion of the acid, and no iron.

GALACTO'DES, (from the same,) milk-warm, and a milky colour. Hippocrates.

GALACTO'PHORA, and GALACTOPOIETICA MEDICAME'NTA, (from *γαλα, milk, and φερω, or ποιω*). Medicines which increase the milk. No medicine seems to have a specific power on these glands; and the only means of increasing the milk is a diet as nutritious, and in such quantity as the stomach can bear; with ease and tranquillity of mind. To force food and drink, in order to increase the milk, will occasion uneasiness and indigestion, and obviate the intention we mean to promote.

GALACTO'PHORI DU'CTUS, (from the same). The LACTEALS. See LACTEA VASA.

GALACTOPO'SIA, (from *γαλα, milk, and πινω, to drink*). The method of curing by a milk diet.

GAL'E'NA INA'NIS. BISMUTH. See BISMUTHUM.

GALA'NGA. GALANGAL; the roots of the *maranta galanga* Lin. Sp. Pl. 3; a grassy leafed plant, which grows in China, and in the East Indies. The dried roots are brought into Europe in pieces of about an

inch thick; branched, full of knots and joints, with several circular rings, of a reddish brown colour on the outside, and of a pale red within.

This root hath an aromatic smell and bitterish biting taste; but the heat and pungency are superior to the bitter. Dr. Lewis observes, that the pungent matter appears to be of the same nature with that of pepper; that it resides not in the volatile oil, but in a resinous matter. Neumann thinks that it resembles ginger in its smell, taste, and chemical composition, but is less agreeable. It is used like the other spices in palsy and every species of debility.

There is a galanga major called *acori radix*, from a variety of the same species, weaker and much more disagreeable. See Lewis's *Materia Medica*. Neumann's *Chemical Works*.

GALA'XA, (from *γαλα, milk*). Is that white line in the heavens called the MILKY WAY; and is a congeries of fixed or nebulous stars. By analogy it is applied to the porosities in the cranium; and Charlton distinguishes the passages and distribution of the chyle in the mesentery by the name of galaxia.

GALBANATUM, a preparation of galbanum now disused.

GALBANUM, GUM, (from the Hebrew *chalbanah*), *albetad, chalbane, gesor*, is the concrete, gummy resinous juice of an evergreen plant, with leaves like those of anise, growing in Syria, the East Indies, and Ethiopia. It is named *ferula Africana, oreosilinum Africanum, anisum fruticosum galbaniferum*, and *anisum Africanum fruticescens* and *ayborzat; bubon galbanum* Lin. Sp. Pl. 364. LOVAGE LEAVED BUBON. The gum is brought to us in pale coloured, semitransparent, soft, tenacious masses, of different shades, from white to brown: the better sorts, when opened, appear to be composed of clear whitish tears, often intermixed with stalks or seeds of the plant. It is rather resinous than gummy, and is more completely soluble in alcohol than in water. The former menstruum indeed leaves only the impurities. It hath a strong unpleasant smell and bitterish warm taste, is unctuous to the touch, and softens in the fingers.

In medical virtue it may be said to be less antispasmodic than asafœtida, and a less powerful expectorant than the ammoniacum. Dr. Cullen thinks that alone

it has little power, but affords a variety, so requisite in the use of antispasmodics. Galbanum is, however, often useful in a flatulent state of the bowels; and is scarcely inferior to asafœtida, a medicine generally unpleasing by its smell, and which can be only given with advantage in pills, which many cannot swallow.

A considerable portion of the virtue of galbanum consists in its essential oil, which rises in distillation, either with water or with spirit; and great care is consequently required in purifying it. For inferior purposes, the best method is to expose it in winter to a sharp frost, and while brittle to powder it: thus the impurities may, in some measure, be separated in the searce: for internal uses it is included in a bladder, and kept in hot water until soft enough to be strained by pressure through an hempen cloth.

Besides the essential oil yielded by distillation with water, an empyreumatic oil is obtained by distilling in a retort without mixture. This oil is of a fine blue colour, but changes in the air to a purple.

It is common to spread galbanum on leather, and to apply it to the belly in hysteric disorders, and in spasms following delivery; but asafœtida, with about one third or one quarter of camphor, and as much opium, is preferable. See Neumann's Chemical Works. Lewis's Materia Medica. Cullen's Materia Medica.

The college of physicians order the following tincture:

Take of galbanum, cut into small pieces, two ounces; proof spirit of wine, two pints; digest with a gentle heat for eight days, and strain. They consider it as a warm antispasmodic, promising to be of service in flatulency, hysteria, and the asthmatic complaints of old people. Pharm. Lond. 1788. If decanted, it is a more powerful medicine; for the finer parts of the galbanum are suspended, and while the medicine is thus strengthened, the elegance of composition is not affected, as on mixture with water it becomes milky. If rectified spirit is employed, about one third of the dose will be sufficient. Externally, galbanum has been applied to expedite the suppuration of indolent tumours; and as a warm stimulating plaster. For the first purpose the following is often successful.

Cataplasmata galbani compositum. R. Rad. lili albi $\frac{3}{4}$ iv. caricarum $\frac{3}{4}$ i. rad. cepæ vulgaris contusæ $\frac{3}{4}$ i. ss. gummi galbani $\frac{3}{4}$ ss. Radix lili et caricæ coquantur, et simul contundantur; postea radix cepæ adjiciatur, et denuo galbanum vitello ovi solutum.

Galbanum is also an ingredient in the *filulæ à gummi, emplastrum lythargyri cum gummi*, and the *emplastrum ad clavos Pharm. Edinensis*.

GA'LBEUM. BRACELETS worn by the Romans; not only as ornaments, but as salutary: so called from the emperor Galba, who is said to have worn them.

GA'LBULÆ, (from *galbus*, yellow; from the colour). See CUPRESSUS.

GA'LBULUS, (from the same). When the skin of the body is naturally yellow.

GALDA GUMMI RESINA. Its source is unknown; but in taste and smell it resembles the gum elemi, and, like it, is reckoned a stimulant and resolvent. The ancients added to these virtues an expectorant quality. It is not at present to be procured.

GA'LE. See MYRTUS BRABANTICA.

GA'LEA, (from *γαλη*, a cat; because it was formerly

made of the skin of that animal). A HELMET. (See PILEUS). In anatomy it is the appellation of the *amnion*; in surgery, of a bandage for the head; in botany, of the upper lip of a ringent corolla or labiated flower. Among diseases, it is by analogy a name for a species of headach, which surrounds the head like a helmet.

GALEANTHRO'PIA, probably from *γαλη*, a cat; and *ανθρωπος*, a man, as it is a species of madness in which a patient imagines himself to be a cat, and imitates its manners.

GALEA'TUS, (from *γαλη*, a helmet). Botanically, it is applied to leaves or flowers which have the shape of a helmet.

GA'LEGA, (from *γαλα*, milk; because it increases the milk of animals, particularly of goats). *Ruta caphraria*, GOAT'S RUE, *galega officinalis* Lin. Sp. Pl. 1062. The root is perennial; on the stalks are pods with oblong kidney-shaped seeds. It is a native of Spain and Italy, where it is eaten as food; but is not noted in medicine.

GA'LEGA NEMOROSA VERA, a species of orobus. *Orobis vernus* Lin. Sp. Pl. 1028.

GA'LEGÆ. A species of senna. *Cassia tora* Lin. Sp. Pl. 538.

GALE'NA, (from *γαληνη*, a calm; supposed to tranquillize the violence of the disease). It was a name of the theriaca before the addition of vipers as an ingredient; and is now the name of a lead ore which contains a little silver. The lead ore is mineralized by sulphur, Haüy, iii. 456.

GALENICAL; the system or the practice of Galen. (See MEDICINA). Galenical medicines is a term employed in opposition to chemical. It was first used to distinguish the antagonists of the chemists; and the preparations are those in which fire is not employed, or at least in a slight degree, and in which no decomposition takes place. Decoctions are indeed galenical remedies; but the decomposition of the vegetable is, in this operation, imperfect.

GALE'NION. The name of an anodyne malagma, in P. Ægineta.

GALEO'PSULON, GALEO'PSIS, (from *καλος*, good, and *οψις*, sight; because it is supposed to assist the sight). *Lamium rubrum*, *urtica iners magna fetidissima*, *stachys fetida*, and HEDGE NETTLE. Unless the synonyms are erroneous, it must be the *stachys palastris* Lin. Sp. Pl. 311. It is supposed to be a good anti-hysteric, and an infusion of the leaves and flowers to be useful in nephritic colics. Boerhaave attributes some salutary qualities to the species called CLOWN'S ALL HEAL, see PANAX COLONI; to the YELLOW ARCH-ANGEL, and SPOTTED ARCHANGEL, see LAMIUM; but neither possesses any remarkable medical virtue.

GALEO'PSIS LUTE'A. See LAMIUM MACULATUM.

GALERICUM APONEUROTICUM. The tendinous expansion over the pericranium.

GALERI'TA, (from *galerus*, a hat; because its leaves are shaped like a hat). See PETASITES.

GAL'I. See INDICUM.

GA'LIA, (from *gallæ*, galls). There are two compositions; one called *pure*, the other *aromatic*; and galls were a part of each composition. *Galia moschata* contained aloes, amber, and musk; sometimes nut-

meg; galia zibettina, civet. The form was that of troches.

GALIA'NCON, (from γαλιος, a weasel, and αγκων, the elbow). See ANCI. Those who have one arm shorter than the other are called *galiancones*, from their resembling a weasel.

GALIUM APARI'NE. See APARINE.

GALIUM VE'RUM. See GALLIUM.

GALL SICKNESS, the name of a remittent bilious fever in the Netherlands.

GALLÆ, (from *Gallus*, a river in Bythia,) *nuces gallæ*, *gallæ maxima orbiculatæ*, *gallæ spinosæ*, *ceses*, **GALLS**; the productions of the *quercus cerris* Lin. Sp. Pl. 1415.

They are hard round excrescences; the nests of an insect called *cynips*, found in the warmer countries on the oak tree. The tear which issues from the wound, made by the insect, gradually increased by accessions of fresh matter, forms a covering to the eggs and succeeding insects. Those galls which have no aperture contain the dead insects. Two sorts are distinguished in the shops; one said to be brought from Aleppo, *galla spinosa*; the other from the southern parts of Europe, called *European galls*. The former are generally of a bluish, greyish, or blackish colour, and verging to a blue, unequal in their surface, difficult to break, and of a close texture: the others are of a pale brownish or whitish colour, smooth, round, easily broken, less compact, and of a much larger size. The two sorts differ in strength; but in other respects are of the same quality: the small, protuberant, bluish, and heavy ones are the best.

Galls are supposed to be the strongest astringent in the vegetable kingdom, without any other smell or taste. Both water and spirit take up nearly all their virtue, though the spirituous extract is the strongest preparation. The powder is, however, the best form; and the dose is from a few grains to half a drachm.

They are not much used in medicine, though they are said to be beneficial in intermittents. Dr. Cullen has cured agues, by giving half a drachm of the powder of galls every two or three hours, during the intermission; and by it alone, or joined with camomile flowers, has prevented the return of the paroxysms. A fomentation, made by macerating half an ounce of bruised galls in a quart of boiling water for an hour, has been found useful for the piles, the prolapsus ani, and the fluor albus, applied cold. An injection simply astringent is made by diluting this fomentation, and used in gleet and leucorrhœa. The camphorated ointment of galls has been found also serviceable in piles after the use of leeches, and is made by incorporating half a drachm of camphor with one ounce of hog's lard, and adding two drachms of galls in very fine powder. Galls are also employed for making black writing ink, and the colouring matter for dyeing black. The decoction of galls is more rough and astringent to the taste; but an infusion in cold water strikes a deeper black with green vitriol. This is not, however, always an accurate test of the degree of astringency. For the properties of the gallic acid, see CHEMISTRY.

See Lewis's *Materia Medica*. Neumann's *Chemical Works*. Cullen's *Materia Medica*.

GALLATU'RA. See ALBUMEN OVI.

GALLICUS MO'RBUS. THE FRENCH DISEASE. See LUES VENEREA.

GALLINACEUS LAPIS; the same with the lapis obsidianus of the ancients; the lave vitreuse obsidienne of Haüy, iv. 494.

GALLINA'GINIS, vel **GALLI GALLINACEI CA'PUT**, (from *gallinago*, a woodcock). When the prostate is cut open, we discover the eminence called *caput gallinaginis*, thick behind and slender before: on each side of this eminence appear the orifices of the vesiculæ seminales.

GALLI'TRICHIS. WILD CLARY.

GALLI'TRICHUM. See HORMINUM.

GALLIUM, (from γαλα, lac, milk; because it coagulates milk). Called *gallion*, **CHEESE RENNET**, **LADY'S BED STRAW**. It is the *gallium verum* Lin. Sp. Pl. 155; a plant with square stalks, and long narrow leaves, which commonly stand eight at a joint in the form of a star. On the tops appear thick clusters of small yellow monopetalous flowers, followed each by two seeds. It is perennial, found in dry waste grounds, and flowers in June and July.

The flowers have a strong, not disagreeable, smell; the leaves scarcely any: but both possess a degree of acidity, and are employ'd in curdling milk. It is on that account styled *cheese rennet*. The whole plant is said to be cooling and astringent; but seldom used in medicine. It is also a name for **MADDER**. See RUBIA SYLVATICA LEVIS.

GALLIUM LATIFO'LIUM FLO'RE LUTE'O. See CRUCIATA VULGARIS.

GALVANISM, (from Galvani, one of its earliest cultivators). Though the phenomena which Galvanism offers are by no means wholly new, yet the discovery of their nature and source, as well as their application, are among the most brilliant improvements of an inventive age. It was long since observed that the electric torpedo, and electric eel, as they were styled, could give, with powers scarcely impaired, many repeated shocks; and philosophers contemplated with astonishment batteries which required no new charge; an efficacy scarcely diminished by exertion. This effect was probably not produced by muscular exertion, for in that system there was no provision for the exercise of such powers. The discriminating organs were cellular, to which a large proportion of nerves could be traced, and anatomical investigation gave no further assistance.

Cotugno, a student of medicine, in 1788, on dissecting a mouse, punctured the intercostal nerve with his scalpel, probably while he touched the other part with his probe, and he felt a shock. The experiment, with some others, was repeated by Vassali; but the only conclusion drawn was, that nature had a power of preserving some portion of the electricity after death. Galvani added to our knowledge by showing us, that the contact of two metals was necessary for the production of this new power, which greatly resembled the electrical; and it was conjectured very early, that these metals acted as doublers of electricity. In the *Annales de Chimie*, we find a very ingenious calculation of their effects, on the principle of the two metals acting in this way (vol. xli. p. 3), in a report made by La Place, Coulomb, Fourcroy, Biot, &c. to the academy respecting the Voltaic pile. But we shall not enlarge

on this part of the subject, because it is scarcely medical, and because the Galvanic phenomena are more nearly connected with the oxidation of the metals. Before, however, we leave this early stage of the history, we may remark, that Sulzer, in 1769, and Fabroni soon afterwards, found that if a piece of silver was placed on the tongue, and a plate of zinc under it, on these metals touching each other a pungent taste was perceived.

Galvani seems rather to have retarded than promoted the knowledge of this science, by connecting it too closely with the fashionable system of electricity, and attempting to find, in the muscular fibre, the two sides of the Leyden phial. The theory of Volta is still different; yet the peculiar action of this singular fluid is not yet well understood. It is shown to exist, by coating, as it is styled, a nerve and a muscle with a different metallic substance, and then joining the distant coatings by some conductor. The muscle is thus powerfully agitated; and even long after life is at end, these motions may be excited. The heart, alone, is most disobedient to this power; and for a reason easily assigned. As an organ of peculiar importance, its nerves are derived from many different sources, communicating with numerous fibres of a very distant origin, in plexuses and ganglia. If then any particular nerve is coated, but a very small portion of the nervous power which regulates that organ is affected.

In the manner, however, described, the influence of Galvanism is very inconsiderable; the Voltaic pile, called from Volta, was contrived to augment its power. This pile consists of plates of zinc and copper, placed alternately, interposing woollen cloths, wetted with a solution of muriated ammonia, between each. It is improved in its powers, and the continuance of its effects, by fixing these plates in a wooden frame, and pouring in the interstices a dilute muriatic acid. It is varied often by using one metal, and different fluids, or supplying the place of metals with other substances, as charcoal and plumbago. These varieties, however, belong rather to the general view of the science than to the present article. For medical purposes, the trough, as it is called, is very generally employed; and the plates are squares, whose sides seldom exceed three inches. Larger ones have been tried; but though they seem to possess a greater Galvanic power, they do not communicate more: after their action they are less completely discharged. The shape is of no consequence; for they are often round, and then called *discs*.

The action of Galvanism on the human body is nearly that of electricity; but as a stimulant, it is less intense, and more steady. The cuticle in animals, and the epidermis in plants and seeds, resist it more powerfully than the electrical influence; and it is necessary often, for the purpose of increasing its power, to puncture the skin, so as to draw some blood. The coats of the nerves have apparently a similar effect; for the influence is greater, the nearer the coating is placed to the part on which the nerves are dispersed, where the coats are thinner, or wholly lost. In general, however, Galvanism does not seem to resemble accumulated electricity; but a weaker charge diffused over a larger surface. In the operation, the metals are oxidated, and the water between them is decomposed, the zinc apparently

yielding the oxygen, and the copper the hydrogen. As the water is seemingly decomposed on each side, it has become a problem to account for the disappearance of the oxygen on the side of the copper, and the contrary. Philosophers have not yet dared to face this difficulty, as it so strongly militates against the modern chemical doctrines. This decomposition of a watery fluid was, however, introduced very early into its medical system; and Galvani, resting on the hypothesis of Cotunnio de Ischiade Nervosa, that sciatica, and many other complaints, arose from the accumulation of a fluid within the nervous sheaths, supposed that it was of service from its influence on the morbid causes. We have no reason, however, to think that it has any effect in this way, though it has been supposed also from this circumstance to change the positive electricity of the healthy body to the negative state.

Galvanism seems chiefly to affect the nervous system, including the muscular fibres, and, indeed, in some degree, fibres of every kind, producing even some apparent contraction in the fibrin of the blood. The nerves and muscles, however, it penetrates more actively than the electrical fluid in its usual state; for it produces powerful contractions, and sensations of pricking and burning in parts insensible, from disease, to electrical sparks, and even shocks. The effects are increased by moistening the skin, and wetting it so much as even to penetrate the cuticle; still more, we have said, if the cuticle is divided: but it often happens that one person may be insensible to its influence, and occasionally the pile is a long time in producing its effects, seemingly from some obstacle, which is removed by an apparently inconsiderable change in the apparatus. It appears to penetrate the nervous system in every direction with equal facility, and probably passes through the minutest fibres, as, after a nerve has been cut and re-united by what seems a condensed cellular or ligamentous substance, the Galvanic influence is not transmitted. It apparently acts by exciting the nervous power; since, like all powerful excitors, it soon destroys irritability. Animals killed by the destruction of this principle soon become putrid; and this is also the rapid consequence of death by putrid miasmata, electricity, and Galvanism.

Galvanism, in consequence of its readily permeating the nerves, has been employed, by Humboldt, to ascertain what parts are nervous, and the real use of some nerves whose office was doubtful. The tendons, probably from the compactness of their structure, are insensible of the Galvanic stimulus. By his experiments it also appears that the third branch of the fifth pair of nerves supplies the organs of taste, and the ninth pair gives activity to the muscles of the tongue, as Galen supposed.

This active principle has been employed with success in restoring persons apparently drowned; and by establishing a communication between zinc and silver wires, introduced into the mouth and anus of small birds, Humboldt has recovered them from asphyxy. Except, however, in deaths from violence, Galvanism is useless; since, in the last struggles, irritability is usually destroyed. It has been recommended to distinguish a case of peculiar difficulty and importance, viz. the existence of amaurosis in cases of cataract. If the two metallic excitors, in a proper position, do not

produce the usual sensations in the retina, the operation will probably be useless, as the sentient power of the nerve is apparently lost.

M. Grappengeisser, the first author who seems to have applied Galvanism to medical purposes, used it chiefly in palsies, and in various weaknesses of the sentient or moving nervous fibres; it has been certainly useful, though obviously inefficacious in diseases arising from an organic defect. Yet, in a very considerable degree of what may be styled organic defect in the structure of the nerve itself, it seems to have been beneficial where this defect occasioned epileptic symptoms (Edinburgh Medical Commentaries, vol. last); and from this we are led to expect some advantages from the remedy, where epileptic paroxysms proceed from either extremity, and rise to the head in the form of an aura. In gutta serena, practitioners have not succeeded by means of Galvanism; and it ought to be remembered, that the very sensible retina seldom recovers its powers after it has been, for even a short time, in a paralytic state.

In cases of spasmodic contraction, as cramp, contracted fingers, or limbs, Galvanism has often relieved; and in lameness from gout it has been successful. In one instance, hydrophobia is said, by Vassalli Eundi, to have been cured by it; but, in sciatica, the same author adds, that it has been occasionally injurious, though in some circumstances he supposes that it may be beneficial. Nervous headaches, and similar symptoms, have been relieved by Galvanism; and Aldini thinks, that in two instances of mental derangement it has been highly useful. In the application of Galvanism to palsies, a remark of M. Pfaff should be attended to, though we believe it has not been confirmed by other practitioners, viz. that the zinc should be applied to the muscles, and the silver to the nerves; for if the arrangement is altered, the irritability of the muscles is diminished rather than increased.

This remedy has been employed in some cases of vitiated secretion. Its effects on the secretions, like those of electricity, are the increase of the discharge; and it is not improbable that where the secreted fluids are diseased from a relaxation of the vessels, Galvanism may be useful. It has been employed also, like electricity, in discussing indolent tumours, and in cataracts, but with no very marked or decided success. A few boasted cures have raised our expectations, but the little permanency of the benefit received has again depressed our sanguine hopes. After repeated experiments about the head, inflammations of the eyes, a catarrhal inflammation of the Schneiderian membrane, an insensibility of the organ of taste, headach, or vertigo, have followed; and Galvanism has been undoubtedly injurious where there was considerable irritability.

On the whole, then, we have not yet received very encouraging accounts of the success of Galvanism in diseases; and we fear that we must resign it, with electricity, as a remedy that promises to be beneficial, but whose advantages have not yet answered the flattering expectations first raised.

We have considered Galvanism only as electricity, but it is probably not exactly the same; and we may, with some advantage, add a few observations on this part of the subject, which, though not strictly medical, may per-

haps admit of some application to medicine. Galvanism will, indeed, produce all the phenomena of electricity; but it cannot be accumulated in non-conducting bodies, or excited by any operation on them. The distinction seems to depend on this, that in the electrical machine, the fluid accumulated on the non-conducters is raised from the earth, or drawn from the atmosphere around; in the Galvanic pile it is the fluid which formed a component part of the conductor, appearing in consequence of its change of capacity in this respect. In the doubler of electricity it is the same; and the electricity of the air appears to be truly Galvanic, since it is owing to the decomposition of water, and consequently a change in the capacity of air that before contained vapour. Conductors of electricity are also conductors of Galvanism, and in the same order. In the following series, viz. gold, silver, copper, iron, tin, lead, and zinc, each will become positive when connected with that which precedes, and negative with that which follows. The metal oxidated gives out the Galvanic fluid; and it may be produced by a single metal, if one part only is changed in its state. The most and least oxidable metals form the most active combinations; and after the metals, charcoal, muscular flesh, spirits, and beer, are conductors in their order. Charcoal is the most, and beer the least, powerful. Various circumstances in common life were little understood previous to the discovery of the Galvanic fluid. As it may be excited by two dissimilar fluids, and one metal, the improved taste of porter from a pewter pot, a fact generally acknowledged, may be owing to this principle; nor is it very absurd to suppose, that two persons in a different state of electricity may excite the Galvanic fluid by the medium of a single metal, as in the management of the Perkinian tractors.

We are not yet sufficiently informed of the influence of different animal substances as conductors or exciters of Galvanism. Galvanic effects probably arise from alternate strata of muscles and nerves; but it is more certain that this fluid acts particularly through the medium of the nerves. This has been denied, because leeches are sensible of this action, and in these animals no nerves have been discovered; but we shall show that they really have a nervous system. Mushrooms are also tolerably good conductors of Galvanism.

In the animal economy, the capacity of the fluids for containing electricity is constantly changing. To the facts adduced under that article, of the different states of the electricity of the fluids of the body, may be added, from the observations of Buyina, that in the shivering fit of fever the electricity is negative. In shivering from fear it is the same; and diseased cats are no longer electrical. Vigour, spirit, and activity in the human body, and probably all animals, are, therefore, connected with the positive, or as we have been willing to style it, with the excess of electricity; languor and disease with its defect. We find, too, in the electrical organs of the torpedo and gymnotus electricus, (for as the only organs in which they differ from other fish, we may presume that they are the seat and source of their peculiar powers,) that the surface is greatly increased by the numerous plates of which they consist, and that a very large proportion of nerves is sent to these plates. When we combine these facts, we shall find reason to conclude that the nerves are the probable sources of the

animal, Galvanic fluid; and that these and the nervous fluids are the same, or nearly related. If in the animal process the excess of electricity disappears, we must look for some reservoir in which it is collected, some storehouse from which it may be issued; and this appears to be the brain and nerves. Such, at least, are apparently the fair conclusions from the facts before us.

Mr. Wilkinson also supposes that the cells of the lungs are really Galvanic organs; and that the electricity of the air is discharged in these cells, where the fluid loaded with carbone (a conductor so powerful as to be discovered in a small proportion, even when mechanically mixed with any body, by means of Galvanism) increases its activity, thus giving a stimulus to the heart. The idea is ingenious, but it must rest on its own basis. We are not aware of any argument that will support or invalidate it. See Wilkinson's Elements of Galvanism. Le Sue's History of Galvanism. Aldini's Experiments. Annales de Chimie; and Philosophical Magazine, *passim*.

GALRE'DA, (from *galrey, jelly*, German). A jelly made by boiling the cartilaginous part of animals. In Paracelsus, it signifies an excrementitious mouldiness.

GAMBO'GIA, (from the province *Cambogia*, where it is produced in the largest quantities). From its supposed virtues, it is called *gunmi ad podagram*, *gunmi gutta*; and by corruption *gotta*, *gutta gamba*, *gamon*, *germandra*, *catagemu*, *gamboidea*, &c.; from its gold colour, *chrysofus*; and from its purgative quality, *succus laxativus*, *succus Indicus purgans*, and *scammonium orientale*; usually **GAMBOGE**.

It is a gummy resinous concrete, brought from the East Indies; not, as has been supposed, the produce of the tree called *coddam-pulli*; but more probably obtained from a shrub of the esula or tithymalus kind, referred by Koenig to a new genus, *stalagmites*. It is usually supposed to be the concrete juice of the *Cambogia gutta* Lin. Sp. Pl. 728; and is brought to us in large cakes and rolls. It is solid, brittle, of a smooth surface, perfectly opaque, free from any visible impurities, of a deep reddish yellow colour, and uniform throughout its whole substance; stains moist hands of a yellow colour; when chewed, it hath little or no taste; but soon after impresses a pungent acrimony and heat, and occasions a dryness in the mouth. It easily melts over the fire, ignites from the flame of a candle, burns with a white flame, and leaves a gray ash.

In medicine, it is chiefly used as a drastic purge; but in small doses, or united with other laxatives, often operates with safety and ease; producing copious discharges by stool. In many constitutions gamboge disagrees with the stomach, and occasions vomiting, with cold sweats, and other marks of dangerous commotion; and in dropsies, if given alone, it sometimes produces faintness from the discharge. The dose is from two grains to ten. Boiling in water is said to lessen its activity; solutions in alkalised water are supposed to act only by stool and urine.

In general, we have not found these observations correct. Rubbed with almonds, from its want of taste, it is a convenient laxative for children; and alkalis have been styled its correctors, but they seem only to change the colour from a yellow to a dull red.

It may be given in doses of three or four grains rubbed down with a little sugar; and repeated every three

or four hours; it then evacuates water freely, both by stool and urine. See **SPIRITUS COCHLEARIE AUREUS**.

It has been recommended also in obstructions of the bowels, in tænia, and in quartans. It, however, too often produces vomiting to be eminently useful in the first complaint; and to destroy a tænia; its dose must be unusually and dangerously large. It is employed, however, with advantage in Madame Nouffler's formula, to assist the action of the fern root. In quartans it is no longer exhibited.

The *gambogæ tinctura ammoniata*, ammoniated tincture of gamboge, has been of considerable service in some cutaneous complaints, if a tea spoonful or two are given every night and morning; and is made by dissolving eighteen grains of gamboge in two ounces of the spirits of ammonia.

Rectified spirit of wine dissolves five sixths, and acquires a deep gold colour from it: water, assisted by heat, takes up the same proportion; but on cooling deposits much of the resin: if the water is first impregnated with an alkaline salt, it is said to deposit none. See Tournefort's *Materia Medica*. Lewis and Cullen's *Materia Medica*.

GA'MMA, GA'MMATA, FERRAMENTA. An instrument mentioned by P. Ægineta, made like the Greek letter Γ , used for cauterising a hernia aquosa.

GA'MMARUS, (from *καμαρα*, an arch, from the vaulted roof of its shell). See **CANCER FLUVIATILIS**.

GA'MON. See **GAMBOGIA**.

GAMPHE'LE. The **CHEEK**. The **JAW**, (from *γαυροῦ*, crooked). See **BUCCÆ**.

GA'GAMON, (from *Γαγλαμν*, a fishing net; which it was said to resemble). The **OMENTUM**; and the name is assigned also to the contexture of nerves about the navel.

GA'NGLIA. See **SESAMUM VERUM**.

GA'NGLION. A primitive in the Greek. In anatomy, it imports a knot in which nerves from different sources are intimately mixed. Where two nerves join together, there is generally a ganglion, or plexus; as may be seen at the beginning of all the nerves of the medulla spinalis, and in many other parts of the body. See **PLEXUS**, and **CEREBRUM**.

In surgery, it is a moveable tumour formed on the tendons; generally about the carpus; but always near the skin, and not attended with any uneasiness. Ganglions are supposed to be formed of lymph, secreted within the vagina of tendons, differing in their form and consistence, though they never suppurate. Mr. Sharp reckons these tumours among those encysted ones called melicris. Dr. Cullen ranks it as a genus in the class *locales*, and order *tumores*, and defines it, a *hard moveable extuberation, fixed upon a tendon*.

Mr. Sharp assures us, that he hath frequently succeeded by making an incision through their whole length, at the same time dividing the ligament of the wrist, and afterwards dressing as in wounds in general. Mr. Warner gives two instances of his successfully extirpating them: he observes, that the objection from danger of wounding the subjacent tendon or ligament is of little importance, since these parts can be generally avoided; and the accident occurs daily in wounds without danger. He recommends the cutting away part of the cyst, and then destroying the rest by digestion. A seton passed through them is a safe and easy cure. See

Sharp's Operations in Surgery, in the chapter on encysted tumours. Warner's Cases in Surgery. Heister's Surgery. Bell's Surgery, vol. v. p. 476.

GANGRÆ'NA, (from γαίω, to feed upon). See MORTIFICATION.

GANGRÆ'NA O'RIS. See CANCRUM ORIS.

GANGRÆ'NA O'SSIS. See SPINA VENTOSA.

GANGRENE SCORBUTIQUE DES GENCIVES. See CANCRUM ORIS.

GA'NNANA, and GANNANAPE'RIDE. See CORTEX PERUVIANUS.

GA'RAB. See ÆGILOPS.

GA'RGALE, GA'RGALOS, GARGALI'SMOS, (from γαργαλιζω, to tickle or stimulate). TITILLATION, IRRITATION, ITCHING.

GARGA'REON, (from the Arabic gargar). See UVULA.

GARGARI'SMA, or GARGARI'SMUS, (from γαργαριζω, and that from γαργαριων, the throat,) anagargariston, diaclyisma, collutorium oris. A GARGLE. It is used for washing the mouth and throat when inflammations or ulcerations are present. A small quantity may be taken into the mouth, moved briskly about, and spit out; or held on the back of the throat, and agitated there by a gentle expiration: if the patient cannot do this advantageously, the liquor may be injected with a syringe. When gargles are required, they should be more frequently repeated than is usual in common practice. Simple gargles are designed for cleansing the fauces, and generally consist of vinegar and honey, with infusions of some of our indigenous aromatics. In cases of putridity, the bark, with mineral acids; decoctions of contrayerva, with tincture of myrrh, and port wine, occasionally with Cayenne pepper, as in the West India gargle, are necessary. See ANGINA and APHTHE.

GA'RARI'SMA ALU'MINIS. See HYPOSTAPHILE.

GA'RGATHUM. A bed on which lunatics were formerly confined.

GA'RON, or GA'RUM. A kind of pickle prepared of fish: at first it was made from a fish which the Greeks called garos; but the best was prepared from mackerel. Among the moderns, garum signifies the liquor in which fish is pickled. With vinegar is called oxygarum.

GARO'SMUM. See ATRIPLEX FÆTIDA.

GAROTI'LLO. See ANGINA GANGRÆNOSA.

GARYOPHY'LLON PLINII. See CASSIA CARYOPHYLLATA.

GAS, (from geist, in the German language spirit). ELASTIC FLUID, AERIFORM FLUID, ELASTIC VAPOUR. The word gas was first employed by Van Helmont to express the spirit which rises from fermenting liquors. By this term we now mean a permanent æri-form fluid, incapable of becoming fluid by cold, and owing its aerial form to its intimate union with caloric. See AER.

GAS PINGUE SULPHU'REUM. The deleterious exhalations from caves, usually the carbonic acid gas; sometimes hydrogenous gas.

GAS SULPHU'RIS. SULPHURIC ACID GAS.

GAS SYLVE'STRE. The subtle spirit which rises from fermenting liquors, carbonic acid gas.

GAS VENTO'SUM. The AIR.

GASCO'IGNI PU'LVIS, (from Gascoigne, the inventor's name). See BEZOAR ORIENTALIS.

GAS'TER, (γαστήρ). In Hippocrates it is usually synonymous with the abdomen; sometimes with the uterus; generally with the stomach.

GASTE'RXANAX. See BITHNIMALCA.

GA'STRICA, (from γαστήρ, the stomach). See GASTRODYNIA.

GA'STRICA ARTE'RIA DE'XTRA, vel GASTRICA MAJOR, proceeds from the hepatica arteria; passes behind the pylorus, and, beyond it, sends out the duodenalis or intestinalis; then runs along the right side of the great curvature of the stomach, to the neighbouring parts, to which, on both sides, it distributes branches, and at last ends in the gastrica sinistra.

GA'STRICA ARTE'RIA SINI'STRA, vel GA'STRICA MINOR, is a branch of the splenica; it runs from the left to the right, along the left portion of the great curvature of the stomach; supplies the omentum with branches called gastro epiploicæ sinistrae, and then communicates with the gastrica arteria dextra: from this union the gastro epiploicæ mediæ are produced.

GA'STRICA FEBRIS. This epithet is usually applied to the bilious remittents, styled fancifully by Pinel *meningo gastric*, and varied as either a remittent or continued fever. By Selle it is styled *glutinosa gastric*, from the quantity of mucous matter in the stomach. See Pinel Nosologie, and Selle Pyretologia.

GA'STRICA VE'NA, EPIPLOI'CA SINI'STRA. See GASTRICA VENA SINISTRA.

GA'STRICA VE'NA RE'CTA; called also *gastro epiploica dextra*. It is sometimes a branch from the vena portæ ventralis, or from its principal branches; goes to the pylorus, to the great curvature of the stomach, and communicates with the gastrica sinistra.

GA'STRICA VENA SINISTRA, goes out from the splenica, at the left extremity of the pancreas, from whence it runs to the great extremity of the stomach, and along the great arch, until it meets the gastrica dextra, sending in its passage branches to the sides of the stomach, and communicating with the coronaria ventriculi.

GA'STRICUS SU'CCUS, (from the same). The GASTRIC JUICE is a thin pellucid fluid, supposed to flow from the glands in the stomach to assist the solution and digestion of the food; but is probably only the remains of former meals. See DIGESTIO.

GASTRI'NUM. See CLAVELLATI CINERES.

GASTRI'TIS, (from γαστήρ, venter). See INFLAMMATIO VENTRICULI.

GASTROCE'LE, (from γαστήρ, the stomach, and κελος, a tumour). A RUPTURE OF THE STOMACH. The tumour is in the upper part of the linea alba; though it has happened that a portion of this viscus has been forced through the fibres of the diaphragm into the lungs. See ABDOMEN.

GASTROCNE'MII, (from γαστήρ, a belly, and κνημη, the leg, or shin bone). Albinus calls these muscles by the name *gemellus*, for each at its origin is a biceps rising from each condyle of the femur: the heads soon join, leave a notch, through which the large vessels and nerves pass, and the whole is inserted into the upper posterior part of the os calcis. The tendon of the soleus, with the tendon of this muscle, forms the tendo Achillis. They form the greatest part of the calves of

the legs. They are sometimes called *gastrocnemii externi*, occasionally *suræ*.

GASTROCNEMIUS INTE'RNUS. See **SOLEUS**.

GASTRO CO'LICA VE'NA, (from *γαστήρ*, the stomach, and *κόλον*, the colon,) is a branch from the mesaraica minor, and soon divided into two, one of which runs to the head of the pancreas, and forms the gastrica recta vena, and the colica recta vena.

GASTRODY'NIA, (from *γαστήρ*, and *ὄδυνη*, pain). *Gastrica, periadysmia*; PAIN IN THE STOMACH; usually a symptom of dyspepsia. When it arises from flatulence it has been styled *pneumatosis*.

GASTRO EPIPLOI'CA, (from *γαστήρ*, the stomach, and *επιπλοον*, the omentum). An epithet for the arteries and veins that go to the stomach and omentum.

GASTRO EPIPLOI'CA VENA. A branch of the gastrica sinistra.

GASTRO DE'XTRA. See **GASTRICA RECTA VENA**.

GASTRO SINI'STRA ARTE'RIA. See **SPLENICA ARTERIA**.

GASTRORA'PHIA, (from *γαστήρ*, the belly, and *ῥαφή*, a suture). **GASTRORAPHY**. This word strictly signifies the sewing up any wound of the belly; yet in common acceptation it implies that an intestine is wounded as well as the belly. This operation is useless in small wounds, but necessary in large ones. The best method is to pass double ligatures in one needle, in order to include the rolls at one end, and to be tied upon them with bow knots on the opposite side, which gives an opportunity of straitening and loosening the knots at pleasure. After passing as many ligatures as seem necessary, the lips of the wound are brought gradually together, and kept so until the knots are tied.

The operation of stitching the bowels can only take place where they fall out of the abdomen, so that we can see the situation and nature of the wound in the intestine. It requires no particular direction; but the end of the ligature must be suffered to hang without the external wound, that it may be more easily removed. See Sharp's and Le Dran's Operations.

GASTROTO'MIA, (from *γαστήρ*, belly, and *τεμνω*, to cut). **GASTROTOMY**. Opening the belly and uterus, as in the Cæsarean operation.

GATRI'NUM. See **CLAVELLATI CINERES**.

GAU'DIUM, (from *chadah*, to rejoice). **JOY**. Is one of the exciting passions, and, in a moderate degree, animates the whole system; renders the pulse free and soft; excites the action of the capillaries; and assists digestion: but if sudden and immoderate, like all violent excitements, it exhausts the irritability, so that madness or sudden death sometimes ensues.

GA'ZAR. See **LAURUS ALEXANDRINA**.

GAZE'LLA. (Indian.) The **AFRICAN WILD GOAT**, which affords the oriental bezoar. *Gazella Africana* is the antelope. See **ANTELOPUS**.

GECCO; **POISON**, peculiarly violent in its operation, procured, it is said, by irritating the most poisonous serpents. With this the Indians infect their arrows.

GE'DWAR, or GE'DWAR. See **ZEDOARIA**.

GEI'SON, (*γεισων*, the eaves of a house). See **VALLUM**.

GELA'SINOS, (from *γελως*, laughter). An epithet for the four middle fore teeth, because they are shown in laughing.

GELA'SMUS, (from the same). See **SARDONICUS RISUS**.

GELATINA, (from *gelo*, to congeal). **GELATINE** is an ingredient in the vegetable as well as the animal kingdom; though the former is more properly styled *gum* or *mucilage*. It is transparent, soluble slowly in cold water, and rapidly at 90°. Alkalis dissolve it, especially when assisted by heat; acids more rapidly. With the nitric acid it is partly converted into malic and oxalic acids. It is insoluble in alcohol; but a small portion may be added to the watery solution without any precipitation.

With tannin, a yellowish white precipitate is thrown down from a solution of gelatine, which forms an elastic adhesive mass, not unlike vegetable gluten, and is a compound of the tannin and gelatine. Indeed the tannin is the most certain test of mucilage in any body. By heat it is decomposed, and yields, in a retort, ammonia, a fœtid oil, zoonic acid, and a porous charcoal, leaving phosphat of lime, muriat of soda, and potash.

Gelatine soon becomes sour, and quickly putrefies. The animal mucilage, which greatly resembles it, is not precipitated by tannin, nor does it become a jelly by evaporation. The jellies of ripe fruits are denominated only from their consistence, which is obtained by sugar.

GELA'TIO, (from the same). **FREEZING**; sometimes the rigidity of the body which happens in a catoché or catalepsis.

GEMA'NDRA. See **GAMBOGIA**.

GEME'LLÆ CYSTICÆ, (from *geminus*, double). See **CYSTICÆ VENÆ**.

GEME'LLI, (from the same). See **GEMINI MUSCULI**.

GEME'LLUS, (from the same). See **GASTROCNEMIUS**, **GEMINUS**, and **BRACHIÆUS EXTERNUS**.

GEMINA'TUS, (from *geminus*, a twin). In botany it signifies having two growing from the same part.

GEMINI; the name given by Albinus to the two muscles which Winslow calls *gemelli*, sometimes named *marsupiales*, because they resemble a purse. They are two flat, narrow, small muscles, situated almost transversely one above the other, between the tuberosity of the ischium and the great trochanter, immediately below the pyriformis; parted by the tendon of the obturator internus. (See also **QUADRIGEMINI**.) The appellation also of twins (see **GENERATIO**); and a name of the extensor carpi radialis. Twins are also called *gemelli* and *didymi*.

GE'MMÆ, GEMMEUS, (from *gemma*, a jewel). *Fossilis sal, lucidum sal, maltheorum, almene, cibarius sal, sal rufus*, **ROCK SALT, FOSSIL SALT, COMMON SALT**, and *sal gem*, from its transparency. It is found in the mountains of Poland, Catalonia, Persia, and the East Indies; and is purified by solution in water, when it becomes the common or alimentary salt. In the mines of Wilizca it is sometimes hard enough to be turned in the lathe into toys and vases. The kind naturally pellucid is chiefly used in medicine; and supposed to be more penetrating than the salt formed by evaporation.

GEMS. See **CAPRA ALPINA**.

GEMU'RSA. The name of an excrescence betwixt the toes.

GE'NA, (from *γενος*, the cheek). The upper part of the face between the nose and ears.

GENE'IAS, (from the same). The downy hairs which first cover the cheek; the name also of a bandage mentioned by Galen, that comes under the chin. See **FASCIA**.

GENE'ION, (from the same). See ANTHEREON.

GENERA'TIO, (from *genero, to beget*). GENERATION. This peculiarly curious and interesting subject has employed the ingenuity and sagacity of physiologists of every age, though with little success. They have approached only the sacred fane; destroyed many ill-founded fabrics; exploded many ridiculous theories; and established the question at least on a secure basis.

Every animal propagates its like; and each being proceeds from an egg. In the lowest classes of animals, however, nature providently guards against the destruction of the species, by an impregnation continued through several generations: and, in some instances, has accumulated individuals in an apparently single body. To take, then, an accurate survey of the whole subject, we must commence at the earliest stage of animated existence.

Naturalists have, at last, agreed, that plants have distinct sexes; and the common experiment in the east on the date tree is admitted to be a general example of what takes place in the animation of the seed, styled its fecundation. We find this animation so perfect, that time scarcely destroys it if the access of the air is prevented. The ground, which has been covered for ages with buildings, will, if turned up, produce the peculiar plants of the soil, and those only. Where gardens have once been an exotic will spring among indigenous plants, claiming the distinction of a denizen. The impregnation of the ovum of an animal will be occasionally, in similar circumstances, lasting; for the tanks in India, though dried for months, will, after the first rains, swarm with eels similar to its former inhabitants. Where the sexes are separated by the force of winds, or other accidents, the former impregnation is continued to many, sometimes even six successive generations. In all these instances, the unvaried form and properties of the species show that the succession is not fortuitous; that the generation is not equivocal.

There is, however, a vicarious mode of reproduction, or rather a mode of increase by buds, where, as we have said, numerous individuals are collected in a single body. This mode is well known in the vegetable kingdom; but it is also found in the lower classes of the animal. The polypus is an instance of this kind. Some snakes possess a similar power of sprouting from buds, and can reproduce a considerable portion after mutilation: many animals of a higher order can reproduce a lost limb. In these cases, some appearances of successive impregnation may be suspected; but as we advance in the scale the power is less. When the operations of nature are more perfect, common resources have no longer an effect; the power of the bud, which can produce a new polypus, is not able to form another man, nor even reproduce the smallest portion.

We find also life more profusely bestowed in proportion to the simplicity of the structure. The production of mites mocks calculation: the elephant seldom produces more than two. Millions are contained in the spawn of a herring; but the human being produces one only. This simplicity of structure does not, however, depend on that of the muscles, for in a caterpillar Lyonnet enumerated some thousands, but on the construction and functions of the nervous system. Two or

three years bring the greater number of animals to their perfection: man requires at least twenty. Yet impregnation is equally the work of an instant; and, in these years, man, by the exertions of his own constitution, by his own efforts, brings forward his body and mind, till the result is a Locke, a Newton, or a Leibnitz. Life then, as by the touch of a Promethean torch, is the illumination of the moment: the constitution of the speck that is animated completes the work. When we survey in this atom the future being, its minuteness surpasses the conception, and its supposed increase appears an impossibility. It is a trite remark, that every thing is great or little by comparison; but it is of more consequence to observe, that our idea of "little" is regulated by our organs. What we can scarcely discern is very minute: what the greatest aid of glasses discovers appears to our minds the limits of existence. But we know it is not so. Light, for instance, has an almost insensible momentum; and we know its velocity is incapable of being measured, and is estimated at an immense rate. What then must be the body? It must be as far beneath the smallest atom that our glasses can discover, as that is to the column of a cathedral. When, then, we reach the smallest point which our organs, with the aid of lenses, can convey to the mind, it is our conceptions only that have attained their limits, in consequence of the imperfection of those channels by which ideas are conveyed. The world below us is apparently as extensive as that above; and we know not but that it may sink to atoms as minute, compared to the smallest we can perceive, as the whole solar system is vast and superior to it.

These reflections will not, we trust, appear misplaced, as they will facilitate our progress in the present consideration, and be applicable in many future disquisitions. We are now prepared then to repeat, with more confidence, that generation consists only in animation; and that the growth is the progressive evolution of organized parts, by the interposition of inorganic matter. To suppose that in the first created animals were contained the germs of every future generation (the Swiss hypothesis styled *emboitement*,) is apparently too extravagant, even with the assistance of our former reflections. It is probable that so "wonderful a piece of work as man" must be for ages forming by the concurrence of second causes. Such is the profusion with which the Creator seems to have bestowed life, that though we would reject the molecules organiques of Buffon in their immediate operation, according to his system, we think it highly probable that in the successive arrangements of the component parts of the more perfect animals they may have some share. The philosopher will perceive the tendency and end of these reflections, which it is unnecessary at present to pursue farther, as inapplicable to the present subject.

From the first exertion of philosophical investigation, it is reasonable to suppose that the source and means of our existence must have employed the reflections of those who were capable of penetrating in their inquiries beyond the narrow sphere which surrounded them; and, at different eras, it was believed that both the male and female contributed to the production; that the male was the only agent, while the female afforded support and nourishment; or that the fœtus was produced and

nourished by the female, and animated only in the moment of generation. We shall speak of each opinion, and its authors, very shortly, in their order.

The first and most obvious opinion was that of Hippocrates and Harvéy. It is indeed highly reasonable, and supported by every appearance: though the more modern systems of Haller, Bonnet, and Spalanzani, must, in some measure, modify and extend this theory, it will not be easy wholly to deny it. The discovery, however, of animalcules in semine masculino, for a time directed the views of physiologists to the second opinion; and Leuenhoeck, its author, eagerly supposed that he could discover among these embryos of each sex. Animalcules, however, are found in every fluid; and these appear only after some time, when a degree of putrefaction has probably taken place. More modern discoveries, also, respecting the changes progressively occurring in incubation, have wholly destroyed this system. Buffon, in his fanciful doctrine of the *molecules organiques*, has improved on this theory, and apparently attributes the production of the fœtus to the union of animated particles from each parent. The whole is embellished by his fancy, and adorned by his eloquence; but we can scarcely admit of their influence, except in more remote arrangements; and indeed the existence of these molecules must be considered rather as a probable idea than a fact, which admits of proof or application.

The discoveries of Haller and of Bonnet respecting the origin and independent life of the chick, *in ovo*, have greatly altered the views of physiologists on this subject: these have been assisted by Dr. Hunter's observations on the human gravid uterus at various periods of impregnation, and the result is the third of the opinions stated, which as the more recent and fashionable, we shall proceed to explain, with its various modifications suggested by different authors, and by the facts themselves.

According to this system, the fœtus pre-exists in the ovarium of the female; and in the moment of impregnation is detached from it. A vesicle remains (the corpus luteum), from whence it was apparently separated, a cavity peculiarly vascular, as is always found when any loss is to be supplied. To this is added, that when twins are contained in the womb, two of these vesicles are found. The ovaria are two spheroidal flattened bodies, inclosed between the folds of the broad ligaments, by which the uterus is, in part, suspended. They have no immediate connection with the uterus; but near them the extremity of a tube, which opens on either side into that organ, hangs with loose fimbriæ in the cavity of the abdomen. It is supposed, then, that in the venereal orgasm these extremities are erected, that they grasp the ovarium, and receive the ovum. This would appear fanciful and hypothetical, but that a perfect fœtus has been found in the ovarium, in these tubes, and even been discovered in the cavity of the abdomen, having apparently eluded the grasp of the fimbriæ. In neither case could the fœtus have ascended from the uterus, for whatever difficulty attends the hypothesis now to be explained, will act with equal force against this idea; and to it must be added, that on the latter supposition the embryo must depart from its nidus, where it is to be supported and nourished; on the former he approaches to it.

We may conclude, then, that the fœtus really pre-exists in the ovarium; but the question remains, how it is animated. The access of the male semen is known to be necessary; but the difficulty which attends the passage of the fœtus into the uterus equally militates against the progress of the semen into the ovarium. It has been eluded by Harvey, who supposes a seminal aura to reach the ovary; and by a Mr. Johnston, who suspects that the semen is absorbed, and carried to this organ through the medium of the circulation. The latter, for many reasons improper to be detailed in a popular work, is not probable; and the aura, when speaking of the fœtus, we have shown to be a vague and unsupported medium. In short, every view of the subject seems to show that the semen has a ready access to the embryo. In the same moment that the one is detached from the ovary and conveyed to the uterus, the other may reach that organ. But the fœtus when in the Fallopian tubes, or the abdomen, is animated, so that it is more probable, that by some action of the uterus and its tubes the semen is conveyed to the ovarium; and every fact shows that the muscular fibres of the uterus are at that moment most highly excited. It is certain, that for the purpose of impregnation the semen must reach the cavity of the womb.

Here then induction ends; and difficulties begin. From this view it may appear obvious, that generation is only the animation of a pre-existing germ; and that as we have shown the fœtus to be an independent being, at least dependent only on the mother for a supply of fluids, we have no difficulty in accounting for its growth, and the successive evolution of its different organs. Such, however, would be the conclusion of a shallow, uninformed physiologist. The union of a male and female of different species, even in the vegetable kingdom, is followed by an hybrid production, partaking the properties of both. The mule, the offspring of a horse and an ass, is a familiar example. In a large family, some of the children will partake the form, the temper, the diseases of the father; others of the mother. This cannot be owing merely to the means of excitement, much less to the small portion of nutriment which the semen can afford, supposing it a nutritious fluid, an idea anxiously supported. Bonnet's mechanical system of a net-work, the meshes of which the semen fills, thus modifying the form, is still less tenable; nor can we escape from the opinion first stated, that the male as well as the female contributes to the formation of the future offspring. The primordial embryo is undoubtedly in the female; but the "man stamps an image of himself," the "world's first wonder," either by an union of principles, or a modification of those which pre-existed, in a manner which will probably never be explained.

We have thus given, in a few words, the substance of numerous extensive disquisitions, endeavouring to distinguish facts from hypotheses. We shall be gratified if it should appear that we have explained the subject comprehensively, so far as it will admit of explanation; more so, if we shall be found to have avoided the pruriencies, which, under the veil of science, are so often indulged, and whose only purpose is to gratify sensuality. See Haller's *Physiology*, lecture 33; also the article *CONCEPTIO* in this work.

GENEVA. GIN. A spirit distilled originally from juniper berries; but at present flavoured by oil of turpentine.

GENIA'LIS ARTE'RIA, (from *genion*, *maxilla*). See MAXILLARIE ARTERIE.

GENICULA'TUS, and **GENI'CULUM,** (from *genu*, a knee, or joint). It is strictly a joint with an articulation; but frequently a joint in general, and synonymous with *nodus*, a knot: hence all roots and pods of plants, divided into joints, are said to be geniculated.

GENIO GLO'SSI, (from *γινίσιον*, the chin, and *γλωσσα*, the tongue). *Mesoglossi*. These muscles arise from the chin, above the genio hyoides, and enter the middle of the tongue to bring it forwards. Winslow thinks that they push the tongue out, retract, or expand it.

GENIO HYOIDE'US, (from *γινίσιον*, the chin, and *hyoides*, the bone of the tongue). *Rectus attollens*. A small muscle arising from a tubercle above the beginning of the mylo hyoides, and inserted into the upper part of the base of the os hyoides.

GENIO PHARYNGE'I, (from *γινίσιον*, and *φαρυγγίς*) *mylopharyngæi* (Douglas). Muscular fibres joined to the side of the genio glossi, and inserted into the sides of the pharynx, and continuing with the genio glossi to the chin.

GENIPI HERBA. See ARTEMISIA.

GENIPI VERUM, is a species of achillæa in Haller, which we have not been able to trace in the system of Linnæus. It is the *achillæa foliis pinnatis, pinnis simplicibus, glabris punctatis*; a strong bitter, and supposed to be useful in diarrhœa, indigestion, and epilepsy.

GENI'STA, (from *genu*, a knee; from the inflection and angularity of its twigs). *Cytisogenista*, *cytissus scoparius vulgaris*. COMMON BROOM; *spartium scoparium* Lin. Sp. Pl. 996. It is a shrubby plant, with numerous angular twigs; the leaves are small, and somewhat oval, set three on a pedicle; the flowers are papilionaceous, and of a deep yellow colour; seeds flat, hard, and brownish, in broad pods; common on heaths and uncultivated sandy grounds; flowers in May and June.

The leaves and tops have a nauseous bitter taste, which they yield by infusion in water and spirit, and which remains concentrated in the extracts. They are commended for their purgative and diuretic powers, and have been successfully employed in dropsies. Half an ounce of the fresh tops are boiled in a pint of water to half a pint, and two spoonfuls given every hour till it operates by stool, or the whole is taken, repeating it every day, or every other day. (See Lewis, and Cullen's *Materia Medica*.) The ashes of broom have been much used in dropsies by the recommendation of Sydenham; and their utility has been confirmed by the experience of other practitioners; but their whole power is supposed to depend upon the alkaline salt, and not on the vegetable from whence it is obtained, though the taste of the ashes shows that they contain no small portion of its essential oil. Lemery recommends the seeds.

An extract, called *extractum cacuminis genistæ*, is ordered to be made by the college of physicians, London. (See CHAMÆMELIUM.) It is given as an aperient and diuretic, in doses from ʒ ss. to ʒ i. in hydropic cases.

GENI'STA CANARIE'NSIS. See ASPALATHUS.

GENI'STA HISPA'NICA, and **GENI'STA JUNCE'A** *Spartium arborescens*, *spartium Hispanicum frutex*, and SPANISH BROOM: *genista Hispanica* Lin. Sp. Pl. 999; common in gardens, flowers in June and July. It is of the same nature as the common broom, but said to be more efficacious.

GENI'STA SPA'RTIUM SPINO'SUM. See ALHAGI.

GENI'STA SPA'RTIUM. *Nepa Theophrasti*, *genista spinosa minor*, *genista Germanica*, Lin. Sp. Pl. 999; and the LESSER FURZE. It is so generally known as not to need a description, and its virtues are insignificant.

GENI'STA SPINO'SA IN'DICA, &c. See BAHEL-SCHULLI.

GENI'STA SPINO'SA MA'JOR; *spartium majus*, *scorpius*, *genistellæ spinosæ affinis*, *bahel-schulli*, *nepa*, FURZE or GORSE, *ulex Europæus* Lin. Sp. Pl. 1045. Its medicinal virtues, if it has any, are the same with those of common broom.

GENI'STA TINCTO'RIA, Lin. Sp. Pl. 998, *chamæspartium genistella*, *tinctorius flos*, GREEN WEED, and DYER'S WEED; found in pasture ground, flowers in June and July, and seems to resemble common broom. See Raii Hist. Plant.

GENITA'LIUM, (from *geno*, or *gigno*, to beget). Diseases of the genital passages.

GENITU'RA, (from the same). The semen masculinum, sometimes the pudendum virile.

GENOU, (from *γενυ*, the knee). See DIARTHROSIS and ENARTHROSIS; but the term is not strictly applicable to the latter species, though used for all.

GENSING, (Chinese). GINSENG, *aralia humilis*, *nisi*, *sisarum montanum Coræense*, *aureliana Canadensis Iroquæis*, *plantula Marilandica*, *panax quinquefolium* Lin. Sp. Pl. 1512.

Ginseng is the root of a small plant growing in China, Turkey, and in some parts of North America, particularly in Canada and Pennsylvania. It is two or three inches long, taper, about the thickness of a little finger, often forked at the bottom; elegantly striated with circular wrinkles; of a brownish yellow colour on the outside, and whitish, or of a pale yellow, within; with one or more little knots on the top, the remains of the stalks of the preceding years, and the marks of the age of the root. The Chinese roots are somewhat paler than those from America, and supposed to be superior as tonics.

Ninzin has been supposed synonymous with ginseng; but it is a root of a different species, similar to, though weaker than that of ginseng: the ninzin root is larger, lighter, and less firm; whitish on the surface, yellow within, with a slight aromatic smell, an acrid bitterish taste, and is a species of sium; *sium ninsi* Lin. Sp. Pl. 361.

The Chinese esteem this root as a general restorative and powerful aphrodisiac; but these qualities it possesses in a very inconsiderable degree. (See Cullen's *Materia Medica*.) Indeed, though the Chinese give such extravagant accounts of its many virtues, from its sensible qualities we conclude it has very little power as a medicine. To the taste it is mucilaginous, and sweet like liquorice, yet accompanied with a degree of bitterness, a slight aroma, and little or no smell: the saccharine matter and the aroma of these roots are

preserved in the watery as well as in the spirituous extract; the latter is pleasantly warm.

A drachm of the ginseng root may be sliced and boiled in a quarter of a pint of water to about two ounces, and may be drunk as soon as it is cool: the dose must be repeated morning and evening; but the root may always be twice boiled. M. Rencaum says that the *hepatica nobilis Tragi* is endowed with the principal virtues of the ginseng. See Raii *Historia Plantarum*. Kempfer's *Amœnitates*. James's *Medical Dictionary*. Lewis's *Materia Medica*. London *Medical Transactions*, vol. iii. p. 34.

GENTIANA. GENTIAN, GREATER YELLOW GENTIAN, FELWORT, of the *European chincona gentiana lutea* Lin. Sp. Pl. 320. The stalk is unbranched and jointed; the leaves oblong, acuminate, ribbed, and set in pairs at the joints; the flowers in clusters at the top of the stalk, of a pale yellow colour, somewhat bell shaped, and deeply cut into five segments; the seeds contained in oblong capsules; the root moderately long, slender, branched, brownish on the outside, and of a deep gold colour within; its pith woody, though more spongy than the rest of the root. It is perennial, a native of the mountainous parts of Germany, Switzerland, and France, from whence the dried roots are brought to us; but the plant is found wild in England.

Sometimes the *thora valdensis* of Ray, or *aconitum pardalianches* of Bauhine, is sold for the gentian. It is known from the true gentian by a paler colour externally, having longitudinal wrinkles; its texture is closer than that of gentian; whitish within, and not bitter; but when chewed only mucilaginous. It is the *ranunculus thora* Lin. Sp. Pl. 775.

The best roots of gentian are of a middling size, of a lively yellow colour, tough, and most free from fibres. The older and larger roots are more porous; the younger and slender more compact.

Neumann obtained from \mathfrak{z} xvi. of the root, by means of rectified spirit \mathfrak{z} vij. ss. of resinous extract; and from water, \mathfrak{z} ix. of a gummy one. The London college directs the watery extract (see *CHAMÆMELI EXTRACTUM*); but the spirituous is preferable: the dose may be from gr. x. \mathfrak{z} ij. or \mathfrak{z} i. In distillation, spirit carried nothing over, and water too little to deserve notice.

It is a strong pure bitter, and by any agreeable addition is rendered very grateful to the stomach. Of all the preparations, the infusion in cold water is the most pleasing and active; but when a warm stomachic is required, the tincture of gentian is to be preferred.

The febrifuge virtues of the gentian root have been supposed equal to those of the Peruvian bark, but in many cases it has failed; yet when joined with galls and tormentil roots in equal parts, and given in proper doses, gentian has cured intermittents in Scotland. (See Cullen's *Materia Medica*.) It is, however, one of the principal bitters now employed by physicians; and as such medicines are supposed to be not only tonic and stomachic, but also anthelmintic, emmenagogue, antarthritic, and febrifuge, this root has as good a claim to these numerous virtues as any other. Bitters are supposed to relieve dyspeptic complaints, though arising from debility of the stomach, more effectually than bark, chiefly from their not producing any stricture on

infarcted viscera. When applied as a tent in wounds, it does not render the lips callous; so that it is often used with advantage for imbibing the moisture in issues, which it also dilates. See Lewis's *Materia Medica*. Raii *Historia*. Neumann's *Chemical Works*.

The officinal preparations of this medicine are the extract above noticed; the compound tincture of gentian prepared as follows:

R. *Gentianæ incisæ et contusæ* p. \mathfrak{z} ij. *corticis exterioris aurant. Hispalensium exsiccati* \mathfrak{z} i. *seminum cardamomi minoris contusorum demptis capsulis* \mathfrak{z} ss. *spt. vinosi tenuioris* \mathfrak{f} ij. Digest for eight days, and strain.

This is an elegant composition, a warm stomachic, and not injured by keeping: it was formerly the tinctura amara Pharm. Lond.

The compound infusion of gentian is made by macerating six drachms and a half of gentian, half an ounce of fresh lemon rinds, and a drachm of dry orange peel in twelve ounces of hot water for an hour. It was the *infusum amarum* of the former *Pharmacopœia*; but two drachms and a half of the gentian root are omitted in the present edition. It is a light pleasant bitter, strengthens the stomach, and restores the appetite: two ounces may be taken twice a day, and some cordial carminative tincture should be added if necessary.

Vinum amarum, Ph. Edin. is prepared by adding gentian root \mathfrak{z} ss. Peruvian bark \mathfrak{z} j. Seville orange peel dried \mathfrak{z} ij. *canella alb.* \mathfrak{z} j. to four ounces of proof spirit, two pints and a half of Spanish white wine. The ingredients should be macerated in the spirit for twenty-four hours, and the wine then added: after three days it may be strained. This is considered a very useful and elegant stomachic medicine.

GENTIANA MINOR, GENTIANA CRUCIATA, Lin. Sp. Pl. 334, and **CROSS WORT GENTIAN**. It grows in Hungary on hills and in dry meadows, but is rarely brought to us.

GENTIANA ALBA. See *LASERPITIUM*.

GENTIANA AMARELLA, Lin. Sp. Pl. 334, resembles the gentian, but is in taste intensely bitter.

GENTIANA ASCLEPIADEA, Lin. Sp. Pl. 329, scarcely differing in medical powers from the other species.

GENTIANA CENTAURIUM. See *CENTAURIUM MINUS*.

GENTIANA NIGRA. See *OREOSELINUM APII FOLIO*.

GENTIANA PURPUREA, Lin. Sp. Pl. 329, **PURPLE GENTIAN**; *cursuta*.

The stem is erect, simple, smooth, strong, succulent, about a foot in height; lower leaves nearly elliptical, ribbed, entire; upper leaves, in pairs, sheath like, concave, embracing the stem, pointed, ribbed, inclosing the flowers; flowers, large, purple, standing in whorls, upon short peduncles; calyx, a deciduous spathe; corolla, bell shaped, purplish, plicated, divided at the limb into five ovated dotted segments; filaments, commonly five, of the length of the germen, and furnished with conical antheræ; germen, oblong; style, cleft, points reflex, furnished with blunt stigmata; capsule, ovate, two celled, containing numerous small seeds; roots perennial, cylindrical, slender, branched, externally brown, internally yellow. It is a native of the Alps, introduced into this country by Saussure in 1768; is a

strong bitter, greatly resembling in appearance and taste the gentian, but in no degree superior, though used by some practitioners of Edinburgh for more than forty years. Dr. Home considers it as a variety of the *gentiana lutea*.

GE'NU, (from γονυ παρα το εις γην νευειτ; because by this articulation the body is bent towards the earth). The KNEE; also the patella, KNEE PAN. The knee is the articulation of the thigh and leg bone; as a ginglymus it admits of only flexion and extension, except in its bent state, when it will allow of a small rotation by the relaxation of the ligaments. This joint is made up of the femur, patella, and tibia; for the fibula does not reach it. The patella in extension is drawn up, in flexion pulled down. Under the ligament of the patella is a sac containing mucus, resembling the synovia. Its strength, as of all joints of the same kind, is on the side. The capsular ligament is large, and admits of the collection of a fluid within it when the swelling appears above and on each side the patella, but chiefly above, on account of the ligaments being thinner. What is called the synovial gland Dr. Hunter concludes is merely fat, like all the glands of a similar kind; and the real synovia is, he thinks, secreted by the vessels of the vascular membrane which covers the cartilages. Besides the capsular ligament, there are two others covering the posterior parts of the condyles of the femur, and fixed into the head of the tibia, between its two cavities; these ligaments are stretched when the leg is extended, and relaxed when the leg is bent, allowing at this time a little lateral motion. Between the tibia and the femur are two semilunar cartilages, thick on their external edges, and thin in their centre; and tied to the tubercle by their horns: they alter their figure according to the situation of the bones, to make the shape of one correspond to that of the other.

It sometimes happens that one or two pieces of cartilage, or bone covered by cartilage, are found loose in the cavity of this joint. Some of these are as large as common garden beans: they are generally flat, oblong, having their edges rounded. Mr. Cruickshank formerly considered them as belonging to the patella; and that, like the *ossa triquetra* in the skull, they were owing to distinct points of ossification: but having found one entirely cartilaginous, and another bony one covered by cartilage, formed on the lower end of the femur, he was convinced of his mistake. In the last mentioned case, Mr. Cruickshank observes that there was a cavity in the lower end of the femur, corresponding to the loose bone, showing a former connection; though, as both surfaces were nearly smooth, its manner was not evident. He supposes that during their growth these cartilages and bones are connected to the neighbouring parts by vessels; and that, when either their determined bulk is completed, or their size too large for the easy motion of the joint, they become loose. When this happens, the synovia, from the irritation, is secreted in greater quantity; the capsular ligament is distended, a degree of stiffness takes place in the motion of the joint, with more or less of external inflammation. The fluid underneath is distinctly felt; and the loose bit of cartilage rises frequently above the condyles of the femur, on the out or inside of the knee,

and may be taken between the thumb and finger through the integuments. When the patient hath walked much, the synovia is sensibly increased; and, on remaining quiet for two or three days, is as sensibly diminished. The symptoms are sometimes so mild as not to need an operation; but it is often the only expedient for relief. Mr. J. Hunter recommends removing them by incision; but thinks the particular spot where the operation is to be performed, as well as the manner of operating, deserve the greatest attention. There is a part of the ligament which receives the basis of the patella during the extension of the leg, and rather resembles cellular membrane than capsular ligament, lying under the lower extremities of the vasti and crureus muscles, before they are inserted into the patella. Mr. Hunter proposes to lay hold of the cartilage or bone, and cut upon them at this place: the incision, he thinks, should be no larger than just to allow of their being easily thrust out. A stitch or two is then to be passed through the divided integuments, but not into the cavity of the joint, and the lips of the wound by these means brought together. If they penetrated the joint, instead of uniting the parts, they would act as setons, and produce inflammation: for by a seton introduced into the tunica vaginalis testis we often obtain a radical cure of the hydrocele. The aim of the surgeon is, if possible, to heal the wound by the first intention; and a piece of sticking plaster, with a proper bandage, and position of the joint, may make stitches unnecessary. Mr. Hunter recollects six or seven cases in which these cartilages were removed by excision, though not exactly in the manner recommended; all of these succeeded except one, where the operation was attended with great inflammation, and followed by an ankylosis of the joint. Other instances of failure have occurred; but there are constitutions where any wound, particularly a penetrating one into the cavity of the joint of the knee, will be attended with danger. The circumstances to be avoided are too much exposing the cavity of the joint; lacerating or bruising of the capsular ligament; not properly closing the orifice in the integuments; or employing a blunt or dirty instrument in dividing them. Each may produce inflammation, and render the operation dangerous; but in tolerably sound constitutions, when performed with the necessary precautions, it is generally safe: when, however, the cavity of the joint is inflamed, the danger is very great. Ligaments and cartilages have fewer vessels than most other parts: they inflame, and suppurate, if exposed to irritation, with greater difficulty; the joint ankyloses, and is destroyed, or the patient sinks under a hectic from absorbed matter, if the limb is not amputated. See Cruickshank's in the *Edinburgh Medical Commentaries*, vol. iv. p. 342, &c. *Hunter's Works*. *Hay's Observations in Surgery*.

GENUFLE'XIO, (from *genu*, the knee, and *flecto*, to bend). KNEELING. In kneeling, the *ossa pubis* are lower than when we stand; and this not only increases the hollow of the loins, and throws the belly and its viscera more forward, but in some measure strains the abdominal muscles; occasioning syncope from the uneasiness. This depression of the *os pubis* in kneeling depends partly on the tension of the *musculi recti anteriores*, the lower tendons of which are, in this situation,

drawn with violence under the condyloid pulley of the os femoris. Winslow.

GENU'GRA, (from *γόνυ*, the knee, and *αγρα*, seizure).

GOUT IN THE KNEE. See ARTHRITIS.

GENU'NI DE'NTES. See DENS and SAPIENTIÆ DENTES.

GENUS, (from *γενναω*, to generate). See CLASSIFICATIO.

GEO'DES LA'PIS, (*λίθος γεαδης*, a stone, so called from *γη*, earth, which it contains). It is rather astringent and drying, somewhat detergent when applied to the eyes, mitigating inflammations in the breast, if mixed with water, and rubbed on it. Dios. lib. v. cap. 169. The fossil usually employed is an ocre, an ore of iron, sometimes a sulphurated iron; but the term by naturalists is confined to rounded stones containing a cavity which is sometimes filled with water.

GEOF. M. M. The abbreviation of Step. Franc. Geoffry Tractatus de Materia Medica.

GEOFFRÆ'A INE'RMIS; from Dr. Geoffry; SMOOTH GEOFFRÆA, OR BASTARD CABBAGE TREE. *Geoffroya inermis*, *foliolis lanceolatis*, of Swartz; of Ayton in the Hortus Kewensis; and of Willdenow, Sp. Pl. vol. iii. p. 1130. See Wright, Philosophical Transactions, vol. lxxvii. p. 507, tab. 10. This tree is a native of Jamaica, distinguished by the name of CABBAGE BARK TREE, OR WORM BARK TREE. The bark is externally smooth, and of gray colour; internally black and furrowed, has a mucilaginous and sweetish taste, with a disagreeable smell, and is considered as a powerful anthelmintic. Dr. Wright, who resided long in Jamaica, has supplied the safest and most efficacious modes of exhibition, from his own experience. It may be given either in decoction, syrup, powder, or extract. The decoction is made by boiling one ounce of fresh dried or well preserved cabbage bark in a quart of water, over a slow fire, till the water resembles deep coloured Madeira. This must be strained off, sweetened with sugar, and used early, as its virtues are soon lost. This syrup is formed by dissolving double the quantity of sugar in any portion of the decoction; and this will retain its virtues for many years. By evaporating the strong decoction of this bark to a proper consistence, the extract is prepared; though it must be continually stirred to mix intimately the resinous part, on which probably its efficacy will depend. The powder requires no directions: it resembles jalap, but is not so heavy.

A strong healthy person may take of the decoction, or syrup, two table spoonfuls; of the extract, three grains; and of the powder, ʒss.—and the dose must be gradually lessened, so that a child of one year should take only of the two first half a table spoonful; of the extract, half a grain; and of the powder, five grains.

These doses may be gradually increased till a nausea is excited; but it is safest to begin with small ones, and gradually increase them. The decoction is given in Jamaica, seldom failing to destroy worms in the intestines, and discharge them in considerable quantities. By frequent use, however, these animals become familiarised to the poison, and it is necessary to stop, or employ other medicines of inferior power. Cold water should not be drunk during its operation, as it is apt

to occasion sickness, vomiting, fever, and delirium. When these occur, or when too large a dose has been given, the stomach must be cleared with warm water; the patient purged with castor oil, and take plenty of lime juice for common drink: vegetable acid is the antidote to this poison.

For Mr. Anderson's account of this bark, and the mode of giving it, see PALMA NOBILIS.

GEOFFROYA SURINAMENSIS. Willdenow, vol. iii. p. 1130.

GEOPILY'SIA. A separation by solution. Ruilandus.

GER. The abbreviation of Gerarde; and employed in quoting Gerarde's Herbal, which was improved by Thomas Johnson.

GERA'NIS, (from *γερανος*, a crane; from its shape resembling an extended crane). A bandage used by the ancients in cases of a fractured clavicle, or a dislocated shoulder.

GERA'NIUM, (from *γερανος*, a crane, because its pistil is long, like the bill of a crane). A bandage used from the days of Hippocrates, now called *spica simplex*. In botany, it is the name for *BATRACHIUM*, CROW'S FOOT, OR CRANE'S BILL; its seed vessel consists of five capsules opening inwards, and containing each a single seed; the flowers are pentapetalous.

GERA'NIUM ROBERTIA'NUM, Lin. Sp. Pl. 955, *gratia dei*, and HERB ROBERT; hath reddish or purplish flowers on one pedicle; the leaves are divided down to the foot stalk into three segments, and these again are deeply cut. It is the only sort used in medicine. Its strong smell, salt, and slightly astringent taste, seem to point out some medicinal powers; and it has been employed to repel the milk in hæmorrhages of the bladder and increased mucous discharges. Externally it has been applied to bubos and ulcers of the mammæ, though disused in the present practice.

GERA'NIUM BATRACHOI'DES, *gratia dei Germanorum*, and CROW'S FOOT CRANE'S BILL; *geranium pratense* Lin. Sp. Pl. 954. It hath two blue, but sometimes white, flowers on one pedicle; the leaves are large, wrinkled, and divided into five or seven segments, which again are deeply cut on their edges.

GERA'NIUM COLUMBI'NUM, *pes columbinus* Lin. Sp. Pl. 956, DOVE'S FOOT, and DOVE'S FOOT CRANE'S BILL; hath purple flowers, standing two on a pedicle; the leaves are shaped like those of mallows, and have long foot stalks.

GERA'NIUM MOSCHA'TUM, Lin. Sp. Pl. 951. MUSCOVY, and MUSKED CRANE'S BILL, *acus mocchata*; hath a number of red flowers on one pedicle; the leaves are indented, oval shaped, set in pairs along a middle rib, which is terminated by an odd one.

GERA'NIUM SANGUINA'RUM, Lin. Sp. Pl. 958, *hæmatodes*, and BLOODY CRANE'S BILL; hath solitary flowers, which on their first appearance are red, but soon change to a bluish colour; the leaves are roundish, but divided almost to the pedicle into five segments, which are often subdivided at the extremities into three.

All these plants are found wild in different parts of this kingdom; they flower in May, June, and July. They have an astringent taste; and this quality is extracted by water as well as by rectified spirit, and, on

evaporating the filtered liquor, remains in the extract. See *Radii Historia*. Lewis's *Materia Medica*.

GE'RARAT. A name in Avicenna for some poisonous animals.

GERMA'NDRA. See GAMBOGIA.

GE'RMANIS O'LEUM. See CARPATHICUM, and MELISSA.

GE'RMEN, (quasi *geramen*, from *gero*, to bear). See BLASTEMA.

GEROCO'MIA, (from *γερων*, an aged person, and *κομια*, to be concerned about,) that part of medicine which relates to old age.

GERO'NSTERRE WATER. See SPADANÆ AQUÆ.

GERONTO'XON, (from *γερων*, an old person, and *ροζον*, a dart,) a small ulcer like the head of a dart, appearing sometimes in the cornea of old people. See BOTHRION.

GE'RULA. A monstrous plant. Paracelsus.

GE'RYON. QUICKSILVER. See ARGENT. VIVUM.

GESN. The abbreviation of *Conradi Gesneri Historia Plantarum*.

GE'SOR. See GALBANUM.

GESTA'TIO, (from *gero*, to carry). See ÆORA.

GESTA'TIO. GESTATION, or PREGNANCY, *cyphoria*. It is the progress of the fœtus from the time of conception to that of parturition. See FÆTUS.

The time of a woman's pregnancy is nine solar months, or about two hundred and eighty days; but the child is sometimes born at seven months, and in a few instances at ten. See *MEDICINA FORENSIS*.

From the moment in which the fœtus is animated, a change takes place in the mother's constitution. Sometimes this is so striking as to be at once perceptible; sometimes it is so trifling that months pass on before any obvious change takes place. The change first perceptible is increased irritability. Fancies the most singular and extravagant possess the mind; objects most cherished lose their interest, and others seem to assume new attractions; the appetite is equally capricious; the sleep is broken and interrupted. The stomach partakes of this caprice; and food, the most alimentary, loses its relish, while the most unpleasing, and apparently disgusting, diet is sought after. At the moment of leaving the bed, sickness and faintness come on; the stomach strains with violence, and nothing, or a little bile only, is discharged. The greater number of these symptoms, however, occur in most instances only about the end of the month or six weeks, and they vary in their number and degree, seldom disappearing till about the middle period, or about two hundred days. In this interval they are often truly distressing. Every kind of food is immediately rejected, faintness follows, and even the night is not free from distressing fancies. In such circumstances art is of little avail. Opiates will sometimes quiet the irregular exertions of the stomach, but it will sometimes fail. The columbo root, in powder or in tincture, is sometimes useful; and the aqua kali, or ammoniæ puræ, will occasionally relieve the vomiting, or the distressing heart burn. In general, something should be taken into the stomach before the expecting mother rises from bed, and a cup of peppermint or camomile tea is the most effectual means of relieving the usual urging.

The cause of these commotions we know not, but they are evidently neither unnatural nor morbid. They

arise probably from the irritation of the uterus, communicated to the stomach, and are the effect of the new unaccustomed motions excited in this very irritable organ. That they are not morbid is sufficiently clear, from their scarcely in any instance producing abortion, and from the child being born healthy and active; though for at least three months, sometimes through the whole period, the mother has never retained a single meal, and is apparently worn to the lowest state of debility; a degree of debility under which some delicate women have sunk. The final cause seems to be the necessity of securing a supply for the fœtus. When a woman is first pregnant, all the evacuations are diminished, and a plethoric state occurs. Nature, at that time, requiring no recruit, rejects every addition: secure in what is provided, all adventitious aid is rejected. Were more accumulated, the embryo might be thrown off by the effort of vessels excited beyond their powers; and vomiting, which, as we have shown, determines to the surface, prevents the uterine vessels from being too much distended. When the uterus rises above the pelvis, when the fœtus has attained the power of motion, and is felt at first in irregular fluttering, and afterwards by more distinct actions, all the supply which the mother can convey is wanted. The scene is then changed: the appetite returns, the sleep is uninterrupted, digestion rapid and perfect, the spirits free and unruffled. So far from irritation suggesting fancied evils, real ones disappear; and, though she sometimes *talks* of the future delivery being fatal, she *acts* as if she looked forward to a numerous offspring, and even to *their* descendants. In short, if there is a period of greater health and activity than any other, it is from the two hundred and fortieth to the two hundred and eightieth day; interrupted only, at last, by the unwieldy size, and probably, through the whole, by a little constipation.

In other cases the practitioner feels greater difficulties. Pregnancy sometimes is not discovered by its appropriate symptoms, and these are occasionally concealed. In the early weeks, the abdomen is said to be flatter than usual: it is at least not fuller; and if obstruction takes place, with none of the appropriate symptoms of pregnancy, *that* is considered as a disease, and active emmenagogues are employed. Luckily, this discharge, as we shall find, is not much in our power. If a woman is married, not advanced in years, even though in a bad state of health, pregnancy should be always suspected. If she has been before regular, the suspicions are stronger; but, if not so, we must still suspect, and avoid any powerful evacuants, till the period when the state can be ascertained by unequivocal symptoms, or by the touch. If the woman is clandestinely pregnant, every artifice is employed to conceal the real symptoms, and the facts are only ascertained by the greatest address. The look of a chlorotic and a pregnant girl greatly differs. In the former the face is sunk; the skin muddy; the breasts flaccid; and the nostrils dry: in the latter, whatever are the symptoms of debility, the skin is clear, the features retain some animation, the breasts are full, and the nipple ruddy. These appearances cannot be disguised; but the state of menstruation is concealed, for by this means they hope to escape from their inconveniences, by the probability of what they style "forcing medicines" being ordered. In every circumstance, however, where the slightest

doubt remains, the prudent practitioner will abstain from active measures, till the period arrives when the tumour, or the touch, will clear all his doubts. The tumour, in these clandestine pregnancies, is attributed to dropsy; and on this head we have already spoken. (See ASCITES.) The touch is more decisive; and, by this means, real pregnancy may be ascertained, and distinguished from scirrhus, or polypus of the uterus. If the woman leans forward on a chair, the surgeon, from behind, introduces his fore or middle finger into the vagina, and moves it round till the point touches the os tincæ. In the virgin state it is smooth and even; the uterus yields to the finger, and may be moved like a light ball with ease. In the first three months the difference is inconsiderable; but the tubercle at the mouth of the uterus is somewhat enlarged, and the womb itself sinks, seemingly, lower in the vagina. These marks are, however, equivocal; for even in the unimpregnated state women differ in these respects. But at about the fifth month, the cervix uteri begins to be distended, and the os tincæ to offer a different sensation to the finger. The tubercle shortens, the orifice expands, the uterus itself is moved with difficulty. At last the os tincæ no longer conveys the idea of a fissure, but of an elliptical tube, and is sometimes at that period wholly beyond the reach of the finger. The tumour, at the same time, affords no unequivocal sign. It is not uniform over the whole abdomen. It does not yield, as if its contents were flatus; there is no fluctuation, as if there were water; no unequal hardness, as if any contained part were scirrhus. The swelling rises from above the pubes, generally leaning to one, very often the right, side: it is circumscribed above, hard, but not considerably or irregularly so; and from the state of the urinary secretion, cannot be confounded with a distended vesica. In the fifth month the uterus extends about half way between the pubes and navel, and the neck of the womb is sensibly shortened. In the seventh month the fundis uteri reaches to the umbilicus; in the eighth, midway between this and the pit of the stomach; in the ninth, to the scrobiculus cordis. After the fifth month, and more decidedly in the further stages, the breasts are full; the areola round the nipple extends, and from a ruddy assumes a brown or blackish hue. In reality, however, after the sixth month deception must be at an end: the facts are decisive.

Not to break the continuation of the subject, we omitted mentioning the distinction between pregnancy and scirrhus, or polypi of the uterus. In the first the weight of the womb is considerable, but the edges of the os tincæ are hard and irregular: in the second we find also considerable weight in the uterus, but the other symptoms of pregnancy are wanting, and it is very generally the disease of advanced life.

During gestation the uterus enlarges not from distention or pressure, for distended organs become thinner, and compressed ones thicker than natural: the womb preserves its former thickness; and even increases to the usual bulk of the gravid state when the fœtus is in the ovary, the Fallopian tubes, or the abdomen. Its substance, during gestation, becomes softer; its veins enlarge, so as to assume the appellation of sinuses; its arteries run in a serpentine direction, and freely anastomose, especially near the placenta, and

open obliquely into this organ. Its fibres are circular, and arise from three distinct sources; the spot where the placenta is attached, and from the orifice of each tube. When the womb rises high, as is usual in a first pregnancy, the ligamenta rotunda are considerably stretched, and pains, striking from the belly downward, are very distressing.

A surgeon is often consulted about the reckoning. It is usual to commence from about the middle of the period between the last return and the suppression; but it is safer to reckon about a week earlier. If the menses return scantily in a woman usually regular, the reckoning should commence about a week before this inefficient recurrence. But the whole should be corrected by the *quickenings*, the period when the child's motion is perceived. This is at first indistinct, resembling rather a flatulence in the bowels; but producing sometimes a deliquium. When thus unequivocally marked, somewhat more than the fourth month may be supposed complete, or from one hundred and thirty to one hundred and forty days. When not thus marked, about a week may be reckoned back from the *certain* feeling of a motion, and that may be fixed on as the same period of pregnancy. When, from the irregularity of the menses, the weakness of the child's motion, and the mother's age, generally connected with the two former, we cannot determine from either circumstance, the state of the tumour must decide. See La Motte's *Midwifery*; Denman's *Midwifery*, vol. i.; and Dr. Hamilton's very excellent *Outlines*.

GESTICULA'TIO, (from *gesticular*, to dance about). GESTICULATION. Oribasius described it as a middle kind of exercise betwixt dancing and mock fighting. It is the expression of the passions and feelings by action, as in the modern pantomime; and was formerly a gymnastic exercise.

GE'UM RIVALE, Lin. Sp. Pl. 717; a plant with little smell, but of an austere taste; a native of North America, where it is celebrated as an astringent and tonic, and employed in diarrhœas, dysenteries, and even supposed a specific for intermittents.

GE'UM URBA'NUM, (γεον). See CARYOPHYLLATA.

GHI'TTA. See GAMBOGIA.

GHORA'KA. See CARCAPULI FRUCTU MALO, &c.

GIALA'PPA. See JALAPA.

GI'BBER, and GIBBO'SITAS, (from *gibbus*, crooked). GIBBOSITY, CROOKEDNESS. The chest and spine are both distorted by a faulty arrangement of the vertebræ. See CYRTOIDES and CYRTOMA.

GI'BBUS, (from *gabah*, a hill, Hebrew). In botany it means having both sides convex.

GI'FFÆ. Tumours behind the ears.

GI'GARUS. See DRACONTIUM.

GIL'ARUM. See SERPYLLUM.

GILIADENSE BA'LSAMUM. See BALSAMUM.

GINGI'BERIS AMARITU'DO, (γινγίβρις). See CANELLA ALBA.

GINGIBRA'CHIUM, or GINGIPEDIUM, (from *gingivæ*, the gums, and *brachium*, the arm, or *pēs*, the foot). The scurvy, in which the gums and arms, sometimes the feet, are affected. See SCORBUTUS.

GINGI'DIUM, (γινγιδιον). See CHEROPHYLLUM.

GINGI'DIUM HISPANICUM. See VISNAGA.

GINGI'VÆ, (from *gigno*, to beget; because the

teeth are generated in them). The GUMS; *ula*, the plural of *ulon*. Pollux distinguishes the flesh on the outside of the teeth from that on the inside, or the part between the teeth: the first is *ulon*; the two last *enulon*: *ula* also sometimes means a tumour on the gums. They are that reddish, compact, fleshy substance which covers the two sides of the whole alveolar border of each jaw, insinuates itself betwixt the teeth, then called *harmos*, and adheres to them. Arteries from the carotids run in the gums, and the nerves are from the fifth pair.

The gums are apt to become spongy, and to separate from the teeth; but the usual cause is a stony crust which forms itself on the teeth. When this calculus is separated, the gums soon recover their former state, especially if rubbed with a mixture of the infusion of roses and the tincture of myrrh. In cases also of ulcerations in the gums, mouth, throat, and fauces, the following gargles are useful.

The alum gargle is made by dissolving two drachms of alum in a quart of barley water, adding three ounces of honey of roses. This is also useful in relaxations of the uvula, and other cases where astringents are necessary.

The myrrh gargle consists of six parts of lime water, three of honey of roses, and one of tincture of myrrh. In scrofulous ulcers, where unctuous applications are inadmissible, it is useful.

The scurvy also affects the gums; and when not manifest in any other part, sometimes appears in the mouth: when a scorbutic disorder invades the whole habit, its first symptom is swollen gums. Sometimes a scorbutic complaint attacks the gums, and occasions heat, pain, and itching in them; if touched, they bleed; white spots, red and inflamed about their circumference, are occasionally observed; and if neglected, especially in young persons, a copious flux of thin fetid saliva is discharged, which corrodes all around it. In Holland it is called the WATER CANCER. Besides proper internal antiscorbutics, and the Peruvian bark in large doses, the best external application is the muriatic acid, diluted with water.

GINGERBREAD, a warm, wholesome bread, composed of flour, treacle, and ginger.

GI'NGLYMUS. A HINGE. See DIARTHROSIS.

GI'NSENG. See GENSING.

GITH, or GIT, (from *ketsa*, Hebrew). See NIGELLA ROMANA.

GITHA'GO, (from *gith*). See NIGELLASTRUM.

GLABE'LLA, (from *glaber*, smooth, because usually without hair). The space betwixt the eye brows.

GLA'BER, (from *galab*, Hebrew). SMOOTH. In botany, applied to the leaf it means having a smooth even surface.

GLABULÆ. See CUPRESSUS.

GLADI'OLUS, (*communis* Lin. Sp. Pl. 52, from the sword-like shape of its leaf). FRENCH CORN FLAG; *xiphium*, *anactorion*. Its root is tuberous and double; the leaves like those of the iris; the flower liliaceous, and divided into six segments. It is cultivated in gardens, and flowers in June. The root is externally discutient; internally alexipharmic; and said to be aphrodisiac. See Raii Hist.

GLADI'OLUS FÆTIDUS. See IRIS FÆTIDUS.

GLADI'OLUS LUTE'US. See IRIS PALUSTRIS.

GLA'MA, or GLA'ME. Sordid and swollen eyes. GLA'NDES UNGUENTA'RIÆ. See MYROBALANI.

GLA'NDIUM, (from *glans*, a nut). See THYMUS.

GLA'NDULA, (from its resembling a nut). *Aden*. A GLAND; a distinct soft body, usually of a reddish colour, which separates a peculiar fluid from the general mass, either injurious to the system, or for some useful purpose in the animal economy. It has been doubted whether an artery without convolution may not be adapted for secretion. It is impossible to prove a negative; yet it appears highly improbable, unless the supposed secretion be merely a serous exhalation.

The glands are roundish bodies, seated in the cellular membrane, generally near the large vessels, from which they receive considerable branches: they are of different consistence, and various colours. Sylvius first divided them into conglobate, now called *lymphatic* and *conglomerate*. (See CONGLOBATA, and CONGLOMERATA GLANDULA). Malpighi added what he called the *folliculus* or *simple gland*; such as are found behind the ears, but more remarkably in the fauces.

Dr. Nicholls divides the glands into sinuous, tubular, and equal. A sinuous gland is one whose several follicles have their own excretory ducts, transmitting their fluid to a common basin, as the kidneys. The tubular is the same with the conglobate gland of Sylvius, of which the testes are an instance. In an equal gland the vessels are branched, as in the liver.

Glands are most commonly divided according to the nature of the fluids they furnish, into mucous, sebaceous, lachrymal, salivary, and biliary; but these distinctions are only the parade of science, and add little to its utility.

Ruysch proves, by subtle injections, that the substance of the glands is vascular, consisting of a ramifying artery, partly terminating in a vein, and partly in an excretory duct. But there is not the slightest evidence that the extremity of the artery forms a continuous canal with the excretory duct. On the contrary, a hollow cavity is probably interposed, in which the fluids stagnate, and in which the change principally takes place. Mr. Hewson, however, thinks that the little globular bodies called *cryptæ* and *folliculæ* are only convoluted arteries.

In reality, however, the structure of glands is little known. From corroded injections we perceive only ramifications of vessels in angles peculiar to the organ, and constant in every individual; and on this regular arrangement a mechanical theory of secretion has been raised. In no instance, however, do we find that the injections pass by continuous vessels into the excretory ducts; and in very few will they, by any management, penetrate so far.

When the glands are swollen only, if hard, they are said to be indurated; if harder, and irregular in their feel, to be scirrhus; if, when hard, they are painful, they are styled incipient or occult cancers; if their hardness and pain continue, carcinomata, or inveterate occult cancers; and if the skin breaks, they are called ulcerated and true cancers.

Indurated glands in children's necks are common, and of little importance. The lymphatic system in the

early periods is large, and from want of irritability often obstructed. These tumours, even though they apparently tend to suppuration, may generally be removed by the use of small doses of calomel, with sea water, in a sufficient quantity, daily to produce a gentle discharge from the bowels. Cicuta, sometimes recommended, is unnecessary, and often injurious. Should the glands not be painful, no application is necessary; but they should be kept perfectly cool. See SCROFULA, SCIRRHUS, CANCER, LUPIA, NÆVUS. Kirkland's Medical Surgery, vol. ii. p. 475.

On the nature and structure of glands see Sylvius, Malpighi, Ruysch, Cowper, Havers, De Bordeu, &c.

GLA'NDULA LACHRYMA' LIS; LACHRYMAL GLAND, is a hard conglomerate gland, situated in a cavity of the os frontis, within the orbit, above the external canthus. From the lachrymal gland, on the inside of the tunica adnata of the eye lid, six or seven excretory ducts perforate the tunica adnata by as many orifices, at the distance of a few lines from the tarsus, and evacuate a saline aqueous fluid, called the tears, between the eye lid and the bulb of the eye. The extremities of very small arteries exhale also a moisture from the whole surface of the tunica conjunctiva, which, mixed with the liquor of the lachrymal gland, and the mucus of the Meibomian glands, moistens and lubricates the eye, and the inside of the eye lids.

GLA'NDULA LACHRYMA' LIS, and INNOMINA' TA. See CARUNCULA LACHRYMALIS.

GLA'NDULA PITUITARIA; a small greyish body, lying between the sphenoidal folds of the dura mater on the sella turcica. It is oval, white or greyish within, and sometimes apparently divided into two lobes. It is covered by the pia mater, and the opening of this covering is the extremity of the infundibulum. It has been supposed the seat of the soul, as it is the only single organ of the brain, but is probably a lymphatic gland.

GLA'NDULÆ CERU' MINIS. See AUDITORIUS MEATUS.

GLA'NDULÆ MYRTIFO' RMES. When the hymen is torn, the broken fimbriæ of the membrane contract and form apparent glands; but their glandular structure has not been ascertained. They are so denominated from their fancied resemblance to myrtle berries.

GLA'NDULÆ ODORI' FERÆ, are situated on the inside and at the lower edge of the glans penis; and secreting a fluid, which thickens by stagnation, and acquires a particular offensive smell. These glands are often inflamed in those who have a long prepuce; and emit a matter exactly similar to that which flows from the urethra in gonorrhœa. It is, however, doubtful whether this discharge be venereal.

GLA'NDULÆ PACCHIONIÆ. Small oval fatty bodies in the longitudinal sinus, which are probably not glandular. See CEREBRUM.

GLA'NDULÆ SUPRA RENA' LES, and RENALES. See CAPSULÆ ATRABILIARIE.

GLA'NDULÆ VASCULA' RES. See COWPERI GLANDULÆ.

GLANDULOSO CA' RNEUS, (from *glandula*, a gland, and *carneus*, fleshy,) an epithet given by Ruysch to some excrescences which he observed in the bladder.

GLANDULO' SUS, (from *glandula*, a gland). Bo-

tanically it is applied to a leaf, which has minute glands on its surface.

GLANS. AN ACORN. It is also a strumous swelling; and a name for a pessary, or a suppository, denominated from its resemblance.

GLANS JO' VIS THEOPHRA' STI, (from the same). See CASTANA.

GLANS PE' NIS, (from the same,) *balanos*, *cuspis*, and *nut*. It is formed by the corpus spongiosum urethræ, turned over the corpora cavernosa penis, and covered by a continuation of the integuments. When the cuticle is removed, every little villous body seems a vessel. In the fifth volume of the Edinburgh Medical Essays, a glans penis is said to have been regenerated after amputation; but of this restoration we have many doubts.

GLANS UNGUENTA' RIA. See BEN.

GLA' STUM, (quasi *calastum*, from Callia, who is supposed to have first used it). WOAD; *isatis sativa*, vel *latifolia*; *isatis tinctoria* Lin. Sp. Pl. 936, is cultivated only for the use of dyers, who obtain from it their best blue; an inferior sort is called by the French *vouede*. The plant is not used in medicine, though it is said to be astringent, probably because the indigo is supposed to be so; but this fœcula is the production of a very different plant, the *indigofera tinctoria* Lin. Sp. Pl. 1061. (See INDICUM.) From the *isatis sylvestris* a volatile salt hath been obtained by fermentation only. This is a variety of the *isatis tinctoria*; but it is a plant of the class *tetradynamia*, many of which afford ammonia. See Lewis's *Materia Medica*. Neumann's *Chemical Works*.

GLA' STUM I' NDICUM. See INDICUM.

GLAUBE' RI SAL; so called from its discoverer or inventor. GLAUBER'S SALT, *sal mirabilis*, *admirabilis*, *sal catharticum Glauberi*, *natron vitriolatum*. The Dauphiny salt is a natural production of this kind, obtained from an earth in the province of Dauphiny in France; but that in general use, and which receives the name of Glauber, its author, is artificial; consisting of a vitriolic acid with the mineral alkali. See CHEMISTRY.

The salt which remains after the distillation of the muriatic acid is directed to be exposed to a strong fire, in an open vessel, to separate the remaining acid, to be boiled in distilled water, strained, and crystallized. Ph. Lond. 1788. In cold weather it will shoot in forty-eight hours, and in warmer weather in about twice the time.

The fineness and largeness of the crystals greatly depend on the quantity of acid. The Edinburgh college directs one part of the oil of vitriol to two parts of sea salt for obtaining the spirit of salt, and the residuum is as nearly of a due degree of acidity as can be ascertained by a general rule.

Mr. Fergus, of Piccadilly, London, says, that from two pounds and half of kelp, and nearly two ounces of the oil of vitriol, he obtained half a pound or more of Glauber's salt. He takes calcined kelp ℥ i. powders, and dissolves it in a glazed earthen pan with boiling water ℥ ij. filters the clear liquor into a similar vessel, adding gradually, when hot, as much oil of vitriol, diluted with somewhat more than an equal part of water as is necessary to saturate it. It is then filtered, evaporated to a pellicle, and crystallized.

The *sal catharticum amarum* is nearly of the same quality with the *natron vitriolatum*, and often substi-

tuted for it. But its basis, instead of the alkali, is magnesia, which is detected by adding an alkali in solution to the sal catharticum, from whence the magnesia is separated. The salts do not, however, differ in their medical properties.

The true natron vitriolatum is apt to lose so much of its water of crystallization as to become opaque, and fall into a white powder. It is applied externally in a cataplasm, by dissolving an ounce of the vitriolated natron in half a pint of water, and reducing it to a proper consistence by crumb of bread. It is applied in those inflammations of the eye where the secretions are deficient; the form is attributed to Dr. Kirkland.

In small doses, plentifully diluted with water, it is laxative and diuretic; in larger ones, cathartic. For the latter purpose it is given from ℥ss. to ℥ij. and, if diluted in water, from one pint to two should be employed, and in that case the dose of the salt may be diminished. It then answers every purpose of the Epsom and similar waters; cools and checks the circulation so much, that Dr. Alston thinks it specific in active hæmorrhages. Gangrenes are sometimes washed with a solution of it in vinegar. It has been supposed, when too freely taken, to attenuate the blood, and produce dropsies. It may perhaps debilitate, by injuring the digestive organs; but can produce little permanent mischief. See Lewis's *Materia Medica*, Glauber, Boyle, Becher, and Stahl.

GLAU'CIUM, (from γλαυκος, blue, from its colour). See PAPAVER SPINOSUM.

GLAU'CO'MA, GLAU'CO'SIS, or GLAU'CE'DO, (from γλαυκος, blue). Mr. Sharp, *Operations of Surgery*, p. 158—163, says, that the glaucoma of the Greeks is the suffusio of the Latins, and the cataract of the present times. (See CATARACTA). Woolhouse, Maitre Jean, and M. St. Yves think it a cataract, with a gutta serena; called *cataracta glaucoma*. In this complication of diseases the operation and all other means are useless, unless to ease pain.

GLAU'CO PHYLLUS, (from γλαυκος, blue, and φύλλον, a leaf). Botanically applied to leaves of an azure or sea green colour.

GLAU'CO'SIS. See CATARACTA.

GLAU'RA. See SUCCINUM.

GLAUX VULGARIS, (from γλαυκος, sea green,) *astragalus glaux* Lin. Sp. Pl. -1069; *glycyrrhiza sylvestris flore luteo*; *fœnum Græcum sylvestre*; *hedysarum glycyrrhizatum*. LIQUORICE VETCH. It grows in thickets and under hedges; flowers in July: the herb and seed are commended for increasing the milk in women's breasts; the root is sweetish, astringent, and diuretic, but very rarely used. This plant is often sold for the galega. Raii Hist.

GLECO'MA HEDERA'CEA. See HEDERA TERREST.

GLE'CHON, (γλεχων). See PULEGIUM VULGARE.

GLECHONITES. Wine impregnated with pennyroyal.

GLEET. See GONORRHEA MUCOSA.

GLE'NE, (γληνη, the socket of the eye,) the cavity of the eye, and the pupil; but it is used to express any slight depression or cavity in a bone which receives another bone in articulation. Cotyle is a similar cavity, but deeper. See Os.

GLENOI'DES, (from γληνη, and ειδος, likeness). The same as glene; but particularly applied to two cavities, or small depressions in the inferior part of the first vertebra of the neck.

GLEUCI'NUM O'LEUM, (from γλευκος, must). GLEUCINE OIL; formerly made by infusing several aromatics in wine and olive oil.

GLEU'COS, (from γλυκυσ, sweet). MUST; sometimes sweet wines. See MUSTUM.

GLEU'XIS, (from the same). Wine in which are much saccharine and extractive matter.

GLISCHRO'CHOLOS, (from γλισχρος, viscid, and γληνη, bile). Bilious viscid excrements.

GLISOMA'RG0. See CRETA ALBA.

GLOBO'SUS, (from globus, a globe). GLOBULAR, round. In botany it is applied to the root.

GLOBULA'RIA FRUTICO'SA. See ALYPIA.

GLO'BUS HYTE'RICUS, (quasi *glomus*, from γαλον, Hebrew, a globe or round ball). In hysteric disorders a ball seems to ascend from the stomach into the throat, so as to threaten suffocation. This seeming ball is flatulence, confined by spasm in the upper orifice of the stomach. When this is relaxed, the air escapes through the œsophagus. The only remedies are laxatives, the warm carminatives, and opiates.

GLO'CHIS, (from γλωχης, the point of a spear). The point of the pubes of plants.

GLOMERA'TUS, (from glomer, a cluë of thread). In botany it means growing together in a globular form.

GLO'SSA, (γλωσσα). See LINGUA.

GLOSSA'GRA, (from γλωσσα, the tongue, and αγρα, pain). A rheumatic pain in the tongue.

GLOSSOCA'TOCHOS, (from γλωσσα, tongue, and κατεχω, to depress). An instrument for depressing the tongue, described by P. Ægineta.

GLOSSOCE'LE, (from γλωσσα, and κηλη, tumour). An extrusion of the tongue.

GLOSSOCO'MA. A retraction of the tongue.

GLOSSOCO'MON, (from γλωσσα, a tongue, and κωμα, to guard). A case for the reeds of a hautboy or glossocomion, and employed as the appellation of an instrument or case for containing a fractured limb.

GLO'SSO PHARYNGÆ'I, (from γλωσσα, and φαρυγγε, pharynx). These muscles are fibres which come from the tongue, running along its lateral edges, from which they are separated as they run backward, and down on the sides of the pharynx, under the stylopharyngæi. (See PHARYNX). The name also of the cephalo pharyngæi.

GLOSSO-STAPHYLI'NI, (from γλωσσα, and σταφυλινης, staphylinus). These two muscles are fixed in the lower and lateral part of the basis of the tongue, whence they run obliquely backward, along the anterior arches of the septum palati, and terminate insensibly on each side near the uvula. They form the substance of the two anterior arches of the palatum molle.

GLO'TTA. See LINGUA.

GLO'TTIS, (from γλωττα, the tongue,) is the narrow aperture at the upper part of the aspera arteria, and covered by the epiglottis when we hold our breath, or swallow. The glottis, by its dilatation and contraction, contributes to the modulation of the voice.

GLU'CINE. An earth lately discovered, but not yet employed in medicine. It is denominated from the sweetness of its salts.

GLUE. Inspissated animal gluten. A good glue impermeable to water may be made by boiling a handful of quick lime, with four ounces of lintseed oil, to the consistence of a paste, and then drying it on iron plates.

GLU'MA, (from γλωφα, *to scrape or bark*). **HUSK, CHAFF;** a species of calyx peculiar to corn or grass, infolding the arista: it is either uniflora; multiflora; univalvis; bivalvis; multivalvis; colorata; glabra; or hispida.

GLUS. See **DYSURIA MUCOSA.**

GLUTÆ'A ARTERIA, (from γλουθος, *the buttock*), is a branch of the hypogastric artery, and generally the largest: near its beginning it sometimes sends out the iliaca minor, and sometimes the small branch that goes from that artery to the os sacrum, and other parts fixed to it; afterwards this artery passes out of the pelvis, in company with the sciatic nerve, through the upper part of the great sinus of the os innominatum, below the musculus pyriformis, and is distributed in a radiated manner to the three glutæi muscles. In its passage it gives branches to the os sacrum, os coccygis, the musculus pyriformis, the muscles of the anus, and to the neighbouring parts of the rectum, forming a particular hæmorrhoidalis interna. It sends twigs to the bladder, and parts near it: and detaches a pretty long branch, which runs down with the sciatic nerve.

GLUTÆ'US MA'XIMUS, (from the same,) *glutæus major*, is a muscle which rises from the posterior lateral part of the os coccygis, from a ligament extended between the os sacrum and the latter bone; from the flat surface of the ilium, where it is connected to the os sacrum; and from the spine of the ilium. Its anterior portion grows tendinous, where it runs over the trochanter major, and makes part of the fascia of the thigh: the posterior is inserted into the hind part of the femur, to assist its extension. This muscle with the glutæus medius and minimus, make up the fleshy part of the buttocks, from which they are denominated.

GLUTÆ'US ME'DIUS, rises as high as the spine of the os ilium, and is inserted into the very uppermost part of the trochanter major, bringing the thigh backward and outward.

GLUTÆ'US MI'NIMUS, rises rather lower than the preceding, and forms a middle tendon inserted into the trochanter major, blended with the medius. It is an abductor of the thigh.

GLU'TEN, (quasi *geluten*, from *gelo*, *to congeal*). **GLUE, LENTOR;** the part of the blood which gives firmness to its texture. (See **BLOOD**). It is also a component part of vegetables, and is particularly found in the husks of grain. It is soluble in alcohol and alkalis; in its properties it approaches very nearly the nature of animal substances, and affords, in distillation, ammonia, containing hydrogen, carbon, and nitrogen. It is obtained also by boiling the expressed juice of cresses, scurvy grass, and many other plants of the tetradynamia class, after it has stood till the colouring matter has separated.

GLU'TIA, (from γλουθος, *the buttock*). See **CEREBELLUM.**

GLU'TOS, (from the same). **A BUTTOCK.**

GLUTTUPA'TENS, (from *gluttus*, *the throat*, and *pateo*, *to extend*). An appellation of the stomach, which is only a dilatation of the œsophagus.

GLYCYME'RIDES MA'GNA. See **CHAMA.**

GLYCYPI'CROS, (from γλυκυσ, *sweet*, and πικρος, *bitter*, from its taste). **WOODY NIGHT SHADE.**

GLYCYRRHI'ZA, (from γλυκυσ, *sweet*, and ρίζα, *a root*). *Liquiritia; dulcis radix; and adifson; glycyrrhiza glabra* Lin. Sp. Pl. 1046. **SMOOTH LEGUMINED,** or **COMMON LIQUORICE,** is a plant with oval leaves, set in pairs along a middle rib; the flowers are small, bluish, and papilionaceous, standing in spikes on naked pedicles; followed by smooth pods, containing flat kidney shaped seeds: the root is long, slender, flexible, of a brownish colour on the outside, and yellow within. The plant is perennial, a native of the southern parts of Europe, and cultivated in England. The roots may be taken the third year after the slips or offsets have been planted. An inferior kind, the glycyrrhiza echinata, is sometimes substituted.

The English liquorice is equal to the foreign; and the root, when carefully dried and powdered, is of a richer and more agreeable taste than when fresh, of a dull yellow colour, but often adulterated by a mixture of flour. The dry root is not inferior to the fresh: but it may be kept moist even in dry sand; wet sand rots it.

Liquorice is almost the only saccharine substance that does not produce thirst; and it was consequently called *adifson*: but this quality arises from the necessity of chewing the root, and partly from the stimulus of a slight bitter combined with its sweetness. It covers the offensive taste of many unpalatable medicines, and does not readily ferment: it has been esteemed attenuant, detergent, diuretic, expectorant, and demulcent; though it has only properties similar to sugar, and is preferable only as a demulcent, since its expressed juice dissolves slowly. It yields all its virtue to water; but spirit dissolves less of the mucilage, and the spirituous tincture and extract are the sweetest.

The extract of liquorice, ordered to be prepared like that of camomile, would be best made by pressing the fresh roots betwixt iron rollers, and inspissating the juice. The usual extract is adulterated by a mixture of the pulp of prunes. See Lewis's *Materia Medica*, and Cullen's *Materia Medica*. Neumann's *Chemical Works*.

GLYCYRRHI'ZA SYLVE'STRIS FLO'RE LUTE'O. See **GLAUX VULGARIS LEGUMINOSA.**

GLYCYRRHI'ZA TROCHI'SCI. See **BECHICA.**

GNAPHA'LIUM, (from γναφαλον, *cotton*, from its soft downy surface). **CUDWEED; albinum.** *Gnaphalium dioicum* Lin. Sp. Pl. 1199.

GNAPHA'LIUM ALPI'NUM. See **LEONTOPIDIUM.**

GNAPHA'LIUM LUTE'UM. See **ELYCHRYSUM.**

GNAPHA'LIUM MARI'TIMUM; called also *gnaphalium marinum, gnaphalium cotonaria; athanasia maritima* Lin. Sp. Pl. 1182; **COTTON WEED, OR SEA CUDWEED.**

All the species of cudweed are astringent, and supposed to be useful in fluxes and hæmorrhages; but not used in this country.

GNAPHA'LIUM MONTA'NUM; pes cati; hispidula; elchrysum montanum flore rotundiore; pilosella minor; a variety (β) of the *g. dioicum*. **MOUNTAIN CUDWEED, OR CAT'S FOOT.** It is very common in France, and a syrup made of it hath been celebrated under the name of *syrupus de hispidula seu œlurofo*.

GNAPHALIVM VETERUM. A species of BASTARD DITANY. See PSEUDO-DICTAMNUS.

GNA'THOS, (from γναπιῶ, to bend, from its curvature). The entire cheek, sometimes only the lower part, between the angles of the mouth and ear, which the Latins call *bucca*; occasionally the jaws and the jaw bones.

GNIDIA GRA'NA, (from *Cnidus*). See CNIDIA GRANA.

GOACO'NEZ. The name of a large tree in America: it affords the balsamum purius, vel album; but the source is unknown. See Raii Hist.

GO'AN. The name of a tree in Persia, of whose ashes putty is made.

GO'BIUS, or GO'BIO, (from *goba*, Hebrew). The fish called the GUDGEON. See AMYGDALOIDES.

GO'GGLES. Spheroidal bodies made of horn or black ivory, to cover the eyes, which are fixed by means of a black ribbon round the head. In the front is a small aperture, and sometimes a glass. They are used to defend weak eyes from dust, and, in cases of squinting, to keep the optic axes in the same direction; but in the latter case they seldom succeed, the patient preferring to see with one eye only.

GOMPHIASIS, (from γομφος, a nail). See AGOMPHIASIS.

GO'MPHIOI, (from the same). See MOLARES.

GOMPHOMA, GOMPHOSIS, or ENGOMPHOSIS, (from γομφος, a nail; *clavatio*). A Greek term for that species of synarthrosis which resembles a nail driven into a piece of wood, of which the teeth in their sockets are an instance.

GONA'GRA, (from γονυ, a knee, and αγρα, a pain,) *gonyalgia*. The gout in the knee.

GO'NE, (from γοινομαι, to generate). The SEED; in Hippocrates the uterus.

GONGRO'NA, (from γογγυλος, a round tubercle in the trunk of a tree). Any hard tumour, but particularly a BRONCHOCELE, q. v.

GONGY'LION, (from γογγυλος, round). See PILULA.

GONOI'DES, (from γων, seed, and ειδος, form,) resembling seed. Hippocrates often uses it as an epithet for the excrements of the belly, and for the contents of the urine, when they resemble seminal matter.

GONORRHŒ'A, (from γων, seed, and ρεω, to flow,) an involuntary efflux of seminal juice: but this is not the proper appellation of the disease to which it is applied, and the term now commonly used is *blennorrhagia*, from βλενος, mucus, and ρεω, to flow, i. e. *mucifluxus*; and to gleets the name *blenorrhœa*, or *mucifluxus flavissimus*, without phlogistic symptoms, is assigned.

Dr. Cullen places this disease in the class *locales*, and order *apocrenoses*; and defines it a preternatural flux of fluid from the urethra in males without any libidinous desires. The first species is *gonorrhœa pura*, or *benigna*, a mucous discharge from the urethra, without dysuria, or lascivious inclination.

2. GONORRHŒ'A IMPU'RA, *maligna, syphilitica*, a discharge resembling pus from the urethra, with heat of urine, &c. after impure coition, to which often succeeds a discharge of mucus from the urethra, with little or no dysuria, called a *gleet*.

3. GONORRHŒ'A LAXO'RUM, *libidinosa*, a pellucid

discharge from the urethra, without erection of the penis, but with venereal thoughts while awake.

4. GONORRHŒ'A DORMIENTIUM, *oneirogmos*, when during sleep, but dreaming of venereal engagements, there is erection of the penis, and a seminal discharge.

The *gonorrhœa benigna* is defined by Dr. Fordyce, "an increased secretion from the mucous glands of the urethra, without infection." The matter discharged is whitish and mild, producing no excoriation, or other disorder, on the parts through which it passes, or on which it falls.

The principal cause is a weakness in the parts which are the seat of the disorder; occasional causes are too frequent purging, violent exercise on horseback, too frequent indulgences, cold, excess of spirituous liquors.

The virulent gonorrhœa is a local inflammation, attended with the discharge of a puriform matter from the urethra in men, and from the vagina in women, preceded by a slight sensation at the end of the penis, like a flea bite; accompanied with a frequent desire of making water, which occasions a scalding, or pricking and burning pain, during the time of its passage, particularly felt at the orifice of the urethra, and a little below it, arising from a stimulus applied to these parts. The lips of the urethra appear full and inflamed; a tension is felt in the penis, and the urinary passage is seemingly straitened, particularly at one part, viz. about half an inch below the orifice of the urethra. At this place also the urine, which is felt like scalding water, gives a hot pungent sensation, almost insupportable, and flows in a small interrupted stream. A little whitish mucus appears about the orifice of the urethra, and, if pressed a little above its extremity, the discharge is increased. The mucus soon assumes a greenish hue, verging to a yellow, and is thin. The disease sometimes appears within twenty-four hours after the infection, and is then proportionally slight; generally between the fourth and fourteenth days. Sometimes, by the violence of the irritation, the secretion of mucus seems to be considerably diminished, so that a very small discharge only takes place, though the other symptoms be extremely violent. In this case the disease hath obtained the very improper name of *gonorrhœa sicca*.

When the inflammation is extremely violent, the irritation produces frequent erections, particularly in bed; and as the frænum is usually inflamed, and will not admit of the usual distention, the penis is incurvated with intolerable pain. In this very exasperated inflammation, the perinæum is red and swollen, and all the parts around the trunk are distended and uneasy. The glans penis swells, and is transparent; the prepuce inflames, and cannot be drawn back, or if back, cannot be brought forward, constituting the disease styled ΡΗΥΜOSIS or ΠΑΡΑΡΗΥΜOSIS, q. v. In the former case a hard cord is sometimes felt extending along the back of the penis, which is an inflamed lymphatic, and sometimes the forerunner of a bubo; but almost universally some ulceration precedes the appearance of a bubo. The seat of the disease is in the urethra, near its extremity; but it sometimes extends to Cowper's glands and the prostate. In the greater number of cases the inflammation goes on gradually increasing for ten days or a fortnight, and then as gradually recedes: the tightness grows less; the mucous discharge thickens and grows whiter, and

at last wholly disappears. In women the seat of the complaint is in the vagina, attended with the pungent sensation as in men; but, except when violent, so that the nymphæ and meatus urinarius are affected, not with such a painful heat of urine. *Sic FLUOR ALBUS.*

The matter of the discharge hath a purulent appearance; but is only the mucus of the urethra or vagina secreted in an unusual quantity, and changed in its colour and consistence by the stimulus applied to the parts; like the mucous discharge from the nose or lungs on taking cold. The discharge from the urethra or vagina was long supposed to arise from an ulcer, and various arguments were adduced in favour of an opinion now rejected. Much stress has been laid on the following fact recorded by Swedjar, from Dr. Stoll; but numerous observations of a similar kind have been made in England, and we want not to go to Vienna to dissect persons who have died while affected with gonorrhœa. "Dr. Stoll had, about the year 1782, the instructive opportunity of dissecting a man who died while labouring under a virulent gonorrhœa. On opening the urethra carefully, he found its internal surface preternaturally red; two of the lymphatics preternaturally white and enlarged; and the puriform matter oozing out from the internal membrane, especially at the lacunæ, where the seat of the disorder was, without the least appearance of an ulceration or excoriation."

A discharge of mucus, if not connected with a venereal taint, even when accompanied with inflammation, is not infectious; and the common gleet, when inflammation is secondarily excited, by high living or violent exercise, is equally innocent. Yet when it has preceded a venereal taint, the greatest caution is necessary. A degree of virus, which makes no impression on a part habituated to its stimulus, may convey infection to another unaccustomed to its action.

The gonorrhœa was for many years considered to be a local effect of that poison which, when introduced into the system, produced syphilis. The conclusion was obvious, as it was received in the same manner, and in the same organs. More attentive discrimination led to doubts on the subject, and to some experiments which, though personal, were scarcely justifiable. It was recollected, that the syphilis appeared more than a hundred years before the local inflammation was observed or described; that the latter often continued for several months without being attended by the former; and that the alteration from syphilis to gonorrhœa was a rare occurrence, not without suspicion of a new infection. These doubts suggested two important alterations in practice. Mercury was disused in gonorrhœa, and cooling medicines, with laxatives, only employed; or the inflammation was at once boldly checked, either by astringents, or by exciting a greater inflammation with a more violent and temporary discharge. The result of these plans is more decisive than a host of arguments. They were, for a long time, treated as dangerous innovations, and numerous are the cases of syphilis said to have been produced by their means. Mercury, however, was gradually considered as less essential to the cure, and no great inconvenience has resulted. Syphilis sometimes apparently arises from gonorrhœa; and it is not surprising that, in such persons, either plan of checking the latter should be also attended with the for-

mer. In fact, both diseases are introduced at the same time; and the criterion of future syphilis, the chancre, sometimes appears very early in gonorrhœa. It is, we believe, absolutely certain that the matter of chancre introduced into the urethra will not produce a gonorrhœa, and the discharge from the urethra inserted under the skin will not produce syphilis. Yet there is little doubt but that the diseases are nearly related; and were we to indulge in speculation, we should suppose that the gonorrhœa was at first derived from syphilis; but that in a series of years, and successive introductions to different constitutions, it assumed a milder form, and became specifically distinct. In the same way it is not improbable that the vaccina may have been originally small pox. The gonorrhœa is undoubtedly, at present, a much more mild disease than on its first appearance, and in many persons can scarcely be called a disease. In former periods, the distressing train of symptoms rendered it truly terrible; and its consequences were swelled, often scirrhus, testicles; fistulæ in the perinæum; unconquerable strictures in the urethra; incontinence of urine, &c. These, excepting probably the strictures, are now comparatively uncommon.

Various are the preservations from gonorrhœa recommended and advertised as nostrums. We should perhaps not greatly assist the cause of morality were we to show how its precepts might be violated with impunity; but perhaps the fatal effects of a momentary deviation from the path of virtue may be sometimes obviated, without holding out encouragement to vice. There is, in fact, no certain preventive; though the danger of infection may be certainly diminished by the most scrupulous cleanness, washing with soap and water, or water to which a small proportion of the aqua kali puri has been added. The proportion should be such as to make a very slight impression on the tongue; and, in producing this effect, the alkali must be very gradually added; if it be first made strong, and afterwards diluted, the stronger alkaline solution dissolves the mucus of the tongue, so that each successive addition of water scarcely makes any difference in the taste, as the tongue is more tender. The poison of the gonorrhœa is applied apparently to the orifice of the urethra; but, in the erected state, when the corpora cavernosa urethræ are distended, the urethra itself is a little inverted; and, when collapsed, the part which before appeared the orifice is the upper portion of the canal. This collapse assists the progress of the poison still a little lower, and it at last rests about a finger's breadth in the urethra. In the use, therefore of preventatives, some of the fluid must be insinuated into the urethra, and a little may be even injected in a more diluted state.

When the idea that this disease was distinct from syphilis began to prevail, practitioners attempted to cure it, at once, by dissolving and discharging the mucus. The means employed was an injection of what was then called the caustic alkali, a weak solution of the kali purum, proportioned in the manner just mentioned. It certainly cured the disease, without any remaining inconvenience; but the inflammation it excited was sometimes so considerable as to be more troublesome than even gonorrhœa, and we are apprehensive that strictures in the urethra have been a frequent consequence. Injections of a solution of hydrargyrus muriatus have been

also recommended, and employed with success; not indeed as a mercurial, but as a stimulant. Each stimulates the mucous glands of the urethra, increases the secretion of mucus, and washes away, in the discharge, the remaining poison. The proportion varies; but about two grains to eight ounces of distilled water is sufficiently strong for men. The vagina is less sensible than the urethra; and in women the proportion should be increased, till it produces a smart pungent pain. This remedy is said effectually to relieve the most obstinate gonorrhœas in that sex.

Another method of extinguishing the disease has been attempted, viz. by exhibiting a large dose of the corrosive sublimate internally. It produces a very violent commotion in the system, in which every spasm, every obstruction, yields; but the remedy has not been sufficiently tried to enable us to decide on its efficacy, or indeed on its safety.

In the CURE OF GONORRHŒA, *vænesection* has been freely recommended. The earlier practitioners used it liberally; but we have said that the disease was, at that time, probably more violent. At present the young and the eager surgeon is so fond of his lancet, that we often find blood drawn, when little necessity appears for any evacuation. The inflammation is, in general, local, and requires rather a steady antiphlogistic plan than any decisive interference. If, however, general fever should come on, should the erections be painful and frequent, bleeding must be freely used, to diminish the general tone. *Purging*, another general remedy for active inflammation, has been too rashly employed. It was usual to give a large dose of calomel at bed time, and the colocynth pill, or some other drastic early in the morning. This plan debilitated the constitution, occasioned gleans, and left the most distressing hypochondriacal complaints. It has been accused also, though perhaps without reason, of producing hernia humoralis and strangury. Yet a plan, which was for so many years continued, could not have been wholly useless, or highly injurious. From its abuse arose probably the chief inconveniences; for we now find an active laxative, about twice in a week, with cooling diet and perfect rest, a ready way of removing even troublesome gonorrhœas.

In the general treatment of the disease, *rest* is of the greatest consequence; and this alone, with little assistance from medicine, will complete the cure. But, with this, every part of the antiphlogistic plan should be employed. The *diet* should be cooling, and even the mildest animal food should be eat sparingly. Milk, vegetables, ripe fruit, and the different farinacea, should constitute the principal nourishment; and the drink consist of barley water, with gum arabic, lintseed tea, toast and water, capillaire, or orgeat with water. It has been usual to dissolve nitre in the drinks; but this remedy is not without suspicion of irritating the urinary organs; and, if given, it should be largely diluted. Cream of tartar is more useful, and may be admitted. Whatever increases the flow of urine renders it less acrimonious, if the medicine is not conveyed to these organs; and a gentle *diuresis* will do little injury, as it will not weaken the tone of the parts. The usual *laxatives*, now recommended, are the neutral salts, castor oil, or senna; and with these two or three motions may daily be procured. Opiates should be given at night, to prevent the

painful erections, and to relieve the pain of the chordee, if it exist; and, to the opium, camphor forms an useful addition.

Topical remedies are important. Frequent bathing the part, and the greatest cleanliness, are requisite; particularly washing under the glans, to prevent the accumulation of the fluids from the odoriferous glands, which produces irritation, inflammation, and often ulcers. Injections are now freely used, perhaps too freely. If emollient only, or gently sedative, they do little injury; but astringent injections in the early periods often prolong the disease, and we suspect, occasion the too frequent consequence of gonorrhœa, strictures. It is not sufficiently considered, that even the introduction of the pipe of the syringe often occasions a greater irritation than the injection itself can relieve. In the earlier stages, the aqua lithargyri acetati, largely diluted, is only admissible; and, with this, sometimes the mucilage of gum arabic, occasionally oil of almonds, may be added. Opium often forms a useful ingredient in such injections, and we have usually added it to milk, separating the curd; but the opium, finely powdered, and united with the oily injections mentioned, is equally useful. To four ounces of distilled water, or oil of almonds, eight drops of acetated litharge is sufficient, and about fifty drops of tincture of opium, or three grains of the substance. One part of acetated ammonia to eight or ten of water, forms a cooling pleasant injection. When the scalding of urine is troublesome, four drops of muriatic acid, added to two ounces of water, is often useful. When the hydrargyrus muriatis is employed, one grain may be added to six ounces of water: sometimes a drachm of purified mercury is mixed with an ounce and half of water, by the means of as much mucilage; but this injection seems to possess no peculiar virtue.

When the inflammatory state is removed, astringent injections are employed. Of the metallic astringents, zinc and copper are the principal; but the astringent balsams are sometimes recommended. Ten grains of vitriolated zinc may be dissolved in four or six ounces of water; a drachm of the cuprum ammoniacale in six ounces of rose water; or ten grains of the blue vitriol in two or three ounces, according to the sensibility of the patient. When the inflammation is considerable and long continued, a mixture of syphilitic infection may be suspected, and mercurials are sometimes, though rarely of service. In such cases, Plenck's powder, or calomel, has been suspended in mucilage, and injected into the urethra, or mercurial ointment has been rubbed in the course of the urethra or the perinæum. When the balsams are employed in injections, about one drachm of the balsam copaibæ may be united with two ounces of water.

When the inflammation is slight, the pain inconsiderable, and the matter glairy, the Peruvian bark may be freely administered, the diet rendered a little more nutritious, and the cold bath employed.

GONORRHŒA BALANI. See GONORRHŒA SPURIA.

GONORRHŒA BENI'GNA. See GONORRHŒA PURA.
GONORRHŒA CHORDA'TA, when accompanied by a chordæe.

GONORRHŒA LIBIDINO'SA. GONORRHŒA LAXORUM.

GONORRHŒA MUCO'SA. A GLEET. Subsequent to gonorrhœa a discharge of matter frequently continues, incapable of conveying any disease, and not attended with inflammation. It appears to be, in general, a discharge from the mucous glands of the urethra, in consequence of the relaxation which has followed increased action; and is occasionally owing to the irritation of very violent purgatives, sometimes to strains, or the various causes of debility. The general remedies are, tonics of every kind, particularly bark and cold bathing, astringent injections, regular and constant exercise. It has been removed by a blister to the sacrum, and, in one instance, by a blister to the perinæum.

Though this disease sometimes yields with the greatest facility, yet a similar complaint, a GLEET, is often peculiarly distressing and obstinate. Doubts have lately arisen, whether it be the same as the true mucous discharge, from a weakness of the glands of the urethra, or whether it is a vitiated secretion, from some change in their organization. The language of Mr. Hunter is highly exceptionable, in a philosophical view, as appearing to assign a reason from merely varying the expression of the fact. To "take on diseased action," or "a habit of action," is saying no more than that a part is diseased, or that a discharge continues from habit; and indeed it has been doubted, by a very respectable author, whether Mr. Hunter has not retarded the progress of science by such jargon, and his inconsequential reasoning, more than he has assisted it by his observations. We have premised these remarks, chiefly as an apology for not employing Mr. Hunter's language, while we are availing ourselves of his facts.

That a gleet arises from weakness of the glands, is highly probable from the nature of its causes; but, were this true, we should find tonics and stimulating applications generally effectual. We need not, however, tell every practitioner how often he is disappointed in the best concerted plans of this kind. If we look at some of the more peculiar causes, they will not greatly assist us. We find a gleet, for instance, generally accompanying a stricture in the urethra; and frequently a swelling of the prostate gland. In each case it cannot be wholly owing to weakness, and we are rather led to suspect some local irritation. If we look at the nature of the discharge, we shall find little additional information; for it consists of globular bodies, floating in a slimy mucus, rather than a serum. From this circle of difficulties we cannot escape but by conjecture. Mr. Hunter supposed it to be owing to a state of the glands, not unlike what occurs in scrofula; and thinks the continued discharge from the eyes, or the tonsils, in consequence of a cold falling on these parts in a scrofulous habit, analogous cases. The discharge of gleet, however, differs in its nature, and in the obstinacy with which it resists the remedies useful in the other complaints. Sea water injected into the urethra has no effect: small doses of mercurials more frequently fail than succeed; nor is it certain that the sea water bath is more effectual than one of fresh. We should rather

suspect that it arises from some obstructions of the glands, from a thickening of their coats during the previous inflammation of gonorrhœa, or the continued irritation of the other causes; but that gleet will sometimes insensibly cease without evident reason, or from remedies which could not make so considerable a change in a short period. It is better, however, to attend to the effects of remedies.

Practitioners have attempted to cure gleet by general medicines, or topical applications. The general medicines are tonics and astringents, or stimulants; but the latter, though they deserve the title by being circulated through the arterial system, act only in consequence of their topical determination. The tonics are, cold bathing, the Peruvian bark, and the preparations of steel: these will sometimes succeed, and as often fail. Each has been occasionally tried for several months without success; and they have been combined with as little effect. Yet the general constitution always derives benefit from this plan; and should we fail in our principal object, our labour is not wholly in vain. The astringents or stimulants are the turpentine and the balsams, the astringent gums and cantharides. The effects of these medicines are not very striking; but Mr. Hunter thinks that if they produce no salutary effects in a short time, they will be useless; and he limits this period to the first six or eight days. They often in this time remove the complaint which recurs on their being discontinued, so that they should be employed long after the discharge has ceased.

Of the astringent gums we have little experience, and believe their power to be inconsiderable; but the stimulus of cantharides has often succeeded. This remedy must be cautiously employed, beginning with very small doses, about fifteen drops of the tincture, which may be gradually increased; as in the irritable state of these organs even a common dose may excite dangerous inflammation.

The topical remedies are, tonics, stimulants, or those of other topical inflammations. The decoction of bark, the solutions of copper, of iron, zinc, and lead, are occasionally employed. There is little room for choice; and we succeed with one or the other apparently by accident. Nothing is so capricious as this disease; *varium et mutabile semper*. The stimulating applications are equally uncertain. We once cured an obstinate gleet by the injection of punch, a remedy suggested in a convivial moment; at another time by green tea. Mr. Hunter mentions a case in which the undiluted extract of Goulard succeeded, apparently by producing a violent inflammation. The introduction of a bougie has had the same effect, and riding post has been equally beneficial. It is, however, an useful precaution, suggested by Mr. Hunter, that previous to the use of stimulant applications, the irritability of the patient should be known; and it should be ascertained whether any inflammation was likely to be conveyed along the urethra to the testes or the bladder. Bougies are sometimes rendered stimulant, by covering them with some active liniment or ointment. In general, the distention irritates sufficiently; but turpentine, mercurial ointment, or a camphorated liniment, will add to their powers. While the use of a bougie is continued, the discharge usually proceeds; but, after some time, about three weeks or a month, it should be omitted, and we may

then judge whether it has succeeded. If the running stops, the cure is usually effectual: if it continues, the remedy, if repeated, will be unsuccessful.

The remedies for topical inflammation are stimulants in the vicinity. Blistering the urethra, in its course, has succeeded. Drawing the electrical sparks, in the course of the canal, has had an equally beneficial effect. The discharge has been stopped by a recent gonorrhœa, and by the recent infection of syphilis, on the appearance of chancres. Venereal connections will sometimes occasion a return, and a recent infection has been suspected; but, in this case, the renewed discharge follows almost immediately, and a mistake is nearly impossible. Violent exercise and free living will also occasionally bring it back, with suspicious symptoms of inflammation; but its quick appearance, the nature of the discharge, its vanishing on rest and low living, soon destroy every apprehension that may have been entertained.

In women, gleans are equally obstinate; but they generally pass under the appellation of *leucorrhœa*. The greater number of remedies mentioned are inapplicable in such cases; and general tonics, with astringent or stimulant injections, can only be employed. But leucorrhœa is so common, and so little disgraceful, that, in such cases, medical assistance is seldom required, unless the discharge is in excess.

GONORRHŒA ONEIROGMIOS. The discharge of semen during sleep.

GONORRHŒA SPURIA, vel BALANI, a discharge from the corona glandis.

GONYALGIA, (from *γόνυ*, the knee, and *αλγος*, pain). See GONAGRA.

GORDIUS. A genus of vermes, which infest the inhabitants of hot climates by burrowing under the skin. There are two species, the *g. aquaticus*, and *g. medinensis*. The former requires no medical treatment: for the latter see DRACUNCULUS.

GORGONIAS. CORAL. When taken from the sea it hardens into a stony substance: an effect supposed to be produced by looking on the gorgons. See CORALLIUM.

GOSSIPIUM, (from *gotne*, whence *gottipium*, Egypti). See BOMBAX.

GO'TTA. See GAMBOGIA.

GOU'TIER. See BRONCHOCELE.

GRACILIS, (from *gracilesco*, to become small). The name of some thin and flat muscles.

GRACILIS INTERNUS. See RECTUS INTERNUS.

GRACILIS ANTERIOR. See RECTUS CRURIS.

GRADATIO, (from *gradus*, a progression). GRADATION is an exaltation of the qualities of metals in degree, by which their weight, colour, and consistence, are brought to greater degrees of perfection; for it has not the power of changing the substance, but only elicits their hidden qualities. Rulandus, Johnson. See EXCITATIO.

GRADUATIO. The solemn academical process, by which a *degree* of doctor of medicine is obtained; a process eluded by some venal universities, and perhaps not always conducted with sufficient strictness. It is eluded also by individuals, who call themselves doctors; and the public give them implicit credit for the title and their pretensions to it. In the university of Edinburgh the following regulations are observed:—

1. No person shall be promoted to the degree of Doctor of Medicine, except on one or two stated days in every year, viz. on the 24th of June, or 12th of September, or the days immediately thereafter.

2. No person shall be received as a candidate, until he has applied during three complete years to the study of medicine, in this or some other university, and has attended to all the branches of the science of medicine; viz. anatomy and surgery, chemistry, botany, materia medica, and pharmacy, theory and practice of medicine, and clinical lectures delivered by professors of medicine, on hospital patients.

3. Whoever is desirous of obtaining a degree, must deliver, before the 24th of March, or 12th of June, a medical dissertation, composed by himself, to some one of the medical professors, that he may peruse it, if necessary correct it, and affix to it a written testimony that he has perused it, with the date when he received it.

4. Then, whoever is desirous of a degree in medicine must communicate his intention to the Dean of the Faculty of Medicine, on or before the 20th of April or June, and at the same time deliver to him his inaugural dissertation, with the testimony of the professor who perused it, to be subjected to the consideration of the Faculty of Medicine.

5. After this he is to undergo a medical examination by the faculty, either *viva voce* or in writing, that no person may be received as a candidate who is not well acquainted with polite literature and the science of medicine. As the professors think themselves bound in honour not to divulge the unfavourable result of an examination, a candidate may be remitted to his studies in this stage of his trials, without injury to his reputation or interest.

6. On the 18th of May, or 6th of August, the candidate shall, in an examination by two professors, in the presence of the Faculty of Medicine, give a farther proof of his advancement in the various branches of medical knowledge enumerated above.

7. To the candidate, after having passed these trials, shall be proposed, by one of the professors, an *aphorism of Hippocrates*, and, at the same time, by another professor, a *medical question*; the former of which, explained by himself, and illustrated by a commentary, and the latter, along with an answer to it, supported by proper arguments, he shall return to the professors, by whom they were proposed on the 28th of May, or 11th of August, and shall defend his commentary, and answer, before the Faculty of Medicine, on the 30th of May, or 18th of August.

8. If, by having duly fulfilled these conditions, the candidate shall deserve to be promoted, he shall receive from two of the professors, two histories of diseases, with questions annexed to them, for the purpose of writing an illustration of the one, and answers to the others. These histories, with the illustrations and answers, he shall deliver on the 12th of June, or 1st of September, to the professor who proposed them, and defend them before the Faculty of Medicine on the 15th of June, or 3d of September.

9. After the candidate has been approved of at his first examination, on the 18th of May, or 6th of August, he shall be permitted to send his dissertation to the

press, and shall deliver eight copies, accurately printed, to the Dean of the Faculty of Medicine, on the 15th of June, or 3d of September.

10. If the candidate, after having printed his dissertation, shall be approved of by the Medical Faculty at his third examination, all these proceedings shall be reported to the Senatus Academicus, by the Dean of the Faculty of Medicine, with whose approbation and authority he shall be ordered to publish his dissertation, and defend it in a meeting of the university, on the 24th of June, or 12th of September; when, if the Senatus shall think fit, the highest medical honours, that is, the degree of Doctor in Medicine, shall be conferred on him, with the usual solemnities, as the reward of his diligence and study.

11. To give greater solemnity to all these proceedings, the Faculty of Medicine shall always meet within the university on each of the above mentioned days, at nine in the morning. And if any candidate shall absent himself at the hour appointed, without sufficient reason, he shall not be permitted, on this occasion, to proceed with his trials, or obtain the degree of Doctor in Medicine.

It is required that all the abovementioned exercises shall be performed in the Latin tongue.

The regulations enacted by the Senate of the University of Glasgow, respecting degrees in medicine, are the following:

1. That before any person can be allowed to be a candidate for a degree in medicine, in this university, he shall appear personally before the senate, and lay before them evidence that, during the space of three years, or sessions of six months each, he has regularly attended in some university or universities, or in some medical school or schools of reputation, the following medical classes, viz. anatomy and surgery, chemistry and pharmacy, the theory and the practice of physic, materia medica, and botany.

2. That he shall bring forward evidence that, during one year at least, he has attended medical classes in this university.

3. That the candidate shall undergo three separate examinations in private, by the medical professors of the university, and write a commentary on an aphorism of Hippocrates, and another on a case of disease propounded to him by the said examiners. The first examination shall be on anatomy and physiology; the second on the theory and practice of physic; and the third on chemistry, materia medica, pharmacy, and botany.

4. That the examiners shall report to the senate their opinion respecting the medical knowledge of the candidate; and if their report be favourable, his name, as a candidate for a degree, shall be entered in the minutes of the senate, and a day fixed, when the candidate shall read his commentaries on the aphorism and case, and answer such questions on the several branches of medical science, as shall be put to him by the examiners, in presence of the senate. If the senate be of opinion that the candidate has shown himself worthy of a degree, it shall be conferred, in presence of the senate, by the vice-chancellor, provided the candidate has not published a thesis, which he may, or may not do, according to his own option; but if he has published a thesis,

he must defend it, and the degree must be conferred in the comitia.

5. The whole of the examinations shall be carried on, and the commentaries on the aphorism and case must be written in the Latin language.

GRA'MEN, (quasi *gradimen*, from *gradior*, to creep along, from the extension of its roots). GRASS.

Grasses are one of the seven natural families, into which all vegetables are distributed by Linnæus. They are defined to be plants which have very simple leaves, a jointed stem, a husky calyx, termed *gluma*, and a single seed. In Tournefort they constitute a part of the fifteenth class, termed *apetalis*; and in the sexual system of Linnæus they are mostly contained in the second order of the third class, termed *triandria digynia*. Wheat, oats, barley, and rye, are grasses improved by culture. Grasses form the fourteenth order in the fragments of a natural method in *Philosophia Bôtanica*, and the fourth of the natural orders at the end of *Genera Plantarum*.

GRA'MEN AVENA'CEUM. See ÆGYLOPS.

GRA'MEN CANINUM; also called *gramen Dioscoridis*; *gramen repens*, and *loliaceum radice repente*; QUICK GRASS; COUGH GRASS; and DOG'S GRASS. The French call it *chien-dent*; *tritium repens* Lin. Sp. Pl. 128. It is a creeping perennial grass, of a whitish green colour, with knotty stalks, bearing a spike of imperfect flowers, somewhat resembling a wheat ear; the roots are whitish, or of a pale yellow, long, slender, jointed at distances, variously bent and interwoven.

The roots are sweetish, mildly aperient, and supposed to be deobstruent, diuretic, useful in ulcers of the bladder, strangury, and calculus biliaris. A considerable quantity of the expressed juice of fresh roots must be taken every day, if any benefit is expected. Sheep and cattle greatly improve in spring by the fresh grass, which produces a diarrhœa, and a discharge often of calculi.

GRA'MEN CRU' CIS, CYPERIO'IDIS, and ÆGYPTIA' CUM, *neiem-elsalib*, are roots in medicine named *cyperi*. The plants which produce them grow in watery places, have leaves and flowers in some measure resembling the water grasses, and are called *cyperus grasses*; ÆGYPTIAN COCK'S FOOT GRASS, or GRASS OF THE CROSS. The roots and plants possess the same virtues as the dog's grass, and are serviceable in the earlier stages of dropsy. They are supposed to correct the bad smell of the breath; to relieve nephritic disorders, colics, and uterine complaints; and are taken in powder and decoction, though the present practice properly disregards them.

The long and round cyperus are produced from the *c. longus* and *esculentus* Lin. Sp. Pl. 67. Some other species, particularly the *c. odoratus*, are employed, and some species of the *carex* occasionally substituted for them.

GRA'MEN DA'CTYLON; also called *dactylon radice repente*; *gramen dactyloides*; *gramen canarium ischami paniculis*; *gramen legitimum*; COCK'S FOOT GRASS. *Panicum dactylon* Lin. Sp. Pl. 85; grows in fields and vineyards, in sandy places: its virtues are the same as those of dog's grass. See GRAMEN CANINUM.

GRA'MEN DA'CTYLON AROMATICUM. See JUNCUS ODORATUS.

GRA'MEN LOLIA'CEUM. See LOLIUM.

GRA'MEN MA'NNÆ; *gramen dactylon esculentum*; *ischæmon sativum*; *festuca fluitans* Lin. Sp. Pl. 111. RUS-
SIA SEED and MANNA GRASS; grows in Germany and
Poland: its seeds are small, oblong, pellucid, white,
of a faint taste, and, when decorticated, similar to
rice.

GRA'MEN PARNA'SSI. See PARNASSIA.

GRA'MEN SPICA'TUM. See PHALARIS.

GRA'MIA. The sordes of the eyes.

GRA'MMA. See SCRUPULUS.

GRA'MME, (*γραμμῆ, a line.*) See IRIS. A French
weight. See WEIGHTS.

GRA'NA INFECTO'RIA KE'RMES. See CHER-
MES.

GRANADI'LLA PERUVIA'NA, (dim. of *granado*,
a pomegranate). See CATAPUTIA MAJOR.

GRA'NAL. An evergreen tree in America of a
poisonous quality.

GRANA'TA MA'LA, (from *granum, a grain*; be-
cause full of small seeds). *Granatum*; *mala junica*;
malum granatum; *malicorium*; POMEGRANATE: *junica*
granatum Lin. Sp. Pl. 676; is a prickly tree or shrub,
with long narrow leaves, deep red flowers, set in bell-
shaped cups of the same colour: the fruit is about the
size of an orange, with a thick, tough rind, externally
brownish, internally yellow, with a juicy pulp, and nu-
merous seeds, called *coccones*, in cells like a honey
comb. It is a native of the south parts of Europe.

The flowers are a mild astringent, similar to those of
the wild pomegranate, which are preferred on account
of their being larger. The pulp of the ripe fruit is a
grateful subacid sweet, and of the same general quali-
ties as the summer fruits. The rind is moderately
astringent, called *cortex granati*; *malicorium*; *psidium*,
and *sidium*: it yields its qualities copiously to water, but
the flower most freely to spirit. Dr. Cullen asserts,
that the strong styptic taste of this bark, and the black
colour it strikes with green vitriol, show sufficiently its
astringent power; and it is commonly supposed to be
among the strongest of this kind. He has frequently
found it useful in gargles; in diarrhœas; and in exter-
nal applications; nor does he think it, internally used,
more dangerous than other astringents. That it can
suppress the catamenia, as has been supposed, seems to
him very doubtful. Its dose, in powder, is from ʒss.
to ʒi. of the infusion, or decoction, an ounce and half.
See Raii Hist. Lewis and Cullen's *Materia Medica*.

GRANATRI'STUM. See CARBUNCULUS.

GRANA'TUS SYLVE'STRIS. See BALAU-
STIUM.

GRANDE'BALÆ, (*quod in grandioribus ætate, nas-
cuntur*). The hair under the armpits.

GRA'ND-GOR. The vernacular Scotch appellation
of LUES VENEREA, q. v.

GRANDI'NES. Tumours on the eyelids, resem-
bling hail stones. See CHALAZA.

GRANDINO'SUM, (from its resemblance to a hail
stone,) Os. See CUBOIDESOS.

GRA'NDO, (*quod, similitudinem granorem habeat*).
HAIL. See CHALAZA and CRITHE.

GRANULA'TIO, (from *granum, a grain*.) the re-
duction of metals into small grains, (see COMMUN-
TIO,) and the raising of the fleshy parts of ulcers in a
healing state.

GRA'NUM, (from *garan, corn*, Hebrew). A grain
weight; the weight of a wheat corn.

GRA'NUM RA'GIUM. See CATAPUTIA MAJOR.

GRA'NUM TI'GLIA. See CATAPUTIA MINOR.

GRA'NUM MO'SCHI. See ABELMOSCHUS.

GRAPHIOI'DES, (from *γραφίς, a pencil*, and *εἶδος*,
a form). See STYLIFORMIS PROCESSUS: the name also
for a process of the ulna towards the wrist.

GRAPHI'SCUS, (from *γραφίς, a style or dart*). An
instrument to extract darts. Diocles invented, and Cel-
sus describes it. †

GRAPHOI'DES, or STYLIFORMIS, (from *γραφίς*,
stylus; supposed to originate from this process of the
temple bone). See BIVENTER MUSCULUS.

GRA'PHOY. BROAD LEAVED LEOPARD'S BANE. See
DORONICUM GERMANICUM.

GRA'TIA DE'I; the name of the HERB ROBERT,
of the HEDGE HYSSOP, and of several other vegetables,
from their supposed salutary qualities. See GERA-
NIUM ROBERTIANUM. GRATIOLA.

GRA'TIA DE'I GERMANO'RUM. See GERANIUM BA-
TRACHIODES.

GRATIO'LA, (see GRATIA DEI). *Digitalis mi-
nima*; *centaurioides*; WATER HYSSOP, and HEDGE HYS-
SOP, *gratiola officinalis* Lin. Sp. Pl. 24. It is a low
plant, with finely serrated leaves, set in pairs on the
stalks without pedicles; the flowers are whitish, jointed,
and surrounded with fibres; perennial; a native of the
south of Europe; raised in our gardens.

The leaves have a nauseous, bitter taste, but no re-
markable smell; they purge and vomit briskly, in the
dose of half a drachm of the dry herb, and of a drachm
infused in wine or water. A slight decoction in milk
operates the most mildly; an extract made from wine is
given to two scruples, or ʒi. and is said to be more
efficacious than the plant itself. Cramer thinks this root
similar to ipecacuanha, and equal to it in diarrhœas and
dysenteries, as well as in the cure of intermittents, and
superior to the decoction of the woods in the lues ven-
neræ. (See Raii Hist. Lewis's *Materia Medica*). It
has been thought also a powerful diuretic and sudorific,
as well as beneficial in mania, gonorrhœa, ozena, ulcers
in the fauces, &c. *Edinburgh Medical Commentaries*;
vol. v. p. 6.

GRATI'OLA CÆRU'LEA. See CASSIDA.

GRATTERO'NA. See APARINE.

GRAVA'TIO, (from *gravo, to burthen*). See CAROS.

GRAVATI'VUS, (from the same,) a pain of the
head, attended with a sense of weight.

GRAVE'DO, (from *gravis, heavy*). A COLD.
Gravedo imports a load in the head, or the running
from the nose, experienced in catarrhus or coryza.
Celsus translates *κορυζα* by the word *gravedo*; and Cœ-
lius Aurelianus by the words *catarrhus ad nares*. Pliny
applies this term to the disease called *caros*; but it is,
properly, that weight or listlessness which accompanies
a diminished perspiration, and, as Dr. Cullen observes,
is generally a symptom of catarrh.

By a cold is usually understood a sudden check of
perspiration, from an improper exposure to cold; the
consequences of which are the lesser degrees of a ca-
tarrh: in its farther advances it is productive of fever,
consumption, and similar disorder.

Persons who easily take cold should use frequently
moderate exercise, and such medicines as strengthen

the general system; as cold bathing, &c. The disposition to take cold may be lessened, by gradually acquiring the habit of being exposed to sudden changes of heat and cold; but this attempt should be conducted with caution, lest the remedy might prove the source of the disease.

Disorders of this kind, in their early period, are speedily relieved by immersing the feet in cold water, just before going to sleep. See CATARRHUS; Dr. Fordyce's Elements, in the article Catarrh; Heberden's Observations in the London Medical Transactions, vol. ii. p. 521; and Stern's Advice to the Consumptive, &c. edit. 7. p. 9. &c.

GRAVI'DITAS, (from *gravida*, to be with child). PREGNANCY; and the extraordinary distention of the abdomen in that state. The period of gravidity or gestation is about nine months, or forty weeks, equal to two hundred and eighty days. It is sometimes, however, pretty certainly prolonged to ten months; and the law, we apprehend, allows eleven, as the utmost limits of possible gravidity. On the other hand, a child lives if born at the end of seven months, probably not earlier. See MEDICINA FORENSIS.

GRAVIDITY SPU'RIOUS. Water in the abdomen; polypi, or water in the uterus; a mola, or unforned mass; and steatomata in the uterus, or Fallopiian tubes; will often produce appearances of gravidity. The uterus itself will enlarge, the breasts swell, and all the appearances of real impregnation take place. We have partly spoken on this subject under ASCITES, q. v. and no situation in which a physician can be placed requires greater delicacy. In general, he should wait till all probability of impregnation is at an end, and then act according to the prevailing circumstances; but by all means be cautious of declaring his opinion till it be fixed on a secure foundation.

GRENE'TTE, (a dim. of *graine*, corn, French). See SANTONICUM.

GRESSU'RA, (from *gradior*, to proceed). See PERINEUM.

GRIEF, is one of the depressing passions; it stops perspiration, renders every muscular action languid; and thus checks the intestinal and biliary discharges, renders the skin sallow, and, by lowering the activity of the nervous power, renders the body more accessible to the influence of infection. It has occasioned death, and the persons are said to die *broken hearted*. One instance is recorded, if we mistake not, by Dr. Whytt, where this organic change was produced by grief. We can easily conceive that the diminished power of the vital may be accompanied with such a diminution of the resistance of the simple solid, as to admit of the impulse of the blood when accumulated in the heart and larger vessels, from the altered determination, to occasion a rupture. Grief, if indulged, produces all the changes which distinguish hypochondriasis. The mind soon recovers its elasticity; but the bodily effects remain often during life, frequently terminating in melancholy and mania. Fretfulness, often confounded with grief, is not dangerous to the constitution, and rather referrible to excess of irritability.

GRIE'LUM. See HIPPOSELINUM.

GRINDERS' ROT. Scythe grinders are subject to a disease of the lungs, from the particles of sand mixed with iron filings. Cork cutters and lime burners are

subject to a similar complaint; and we once saw it in an elegant and delicate young female, from an internal causc. See CALCULUS.

GRIPHO'MENOS, (from *γριφος*, a net, surrounding the body.) Pains which extend from the loins to the hypochondria.

GROSSULA'RIA, (from *grossus*, an unripe fig,) *uva crispa*, and GOOSEBERRY BUSH. It flowers in April, and its fruit ripens in July. The unripe fruit is said to abate the longings of pregnant women. The ripe fruit, if the skins are not swallowed, is nutritive, digestive, and cooling.

GROSSULA'RIA NON SPINO'SA. See RIBES.

GRO'SSUS, (from *garas*, Hebrew). See FIGUS SATIVA.

GRO'TTO DEL CA'NI. A grotto near Naples, in which dogs are suffocated. The deleterious vapour is carbonic acid air, which rises only about eighteen inches. A man, therefore, is not affected; but a dog forcibly held in, or who cannot rise above it, is soon killed, unless taken out. He is recovered by plunging him in an adjoining lake.

GROTTO DEL SERPI. The grotto of the serpents, described by Kircher who visited it. It is near the village of Sassa, not very distant from Braccano, in Italy, filled with warm vapour, from some subterraneous apertures, without any apparent gaseous or other impregnation. Patients affected with lepra, elephantiasis, palsy, or gout, are said to be relieved by these vapours; and the relief is, in part, attributed to some serpents, which are not venomous, but which are numerous in this cavity, particularly in the spring, and are said to lick the diseased parts. The exuvia of serpents abound in the grotto, and are suspended on the trees, apparently to cherish the delusion; but the benefit is wholly derived from the warm water.

GROUND NUTS, *arachis hypogæa* Lin. Sp. Pl. 1040, is a leguminous plant, originally from Africa, but now cultivated in all the European establishments. Its calyx is divided into two parts, the upper of which is semitrid, and the inferior lanceolated; the corolla papilionaceous, almost reversed. It has nine monadelphous stamina, and the tenth free and barren; a superior ovarum, which becomes an oblong, cylindrical, reticulated pod, opening with difficulty, and containing two or three seeds. The leaves are alternated, winged, without an odd one; each composed of four oval leaflets, with a membranous stipula at their base, divided into two.

The flowers of the arachis are placed in the axillæ of the leaves. The upper ones, though perfect, are abortive; but the lower bend and hide themselves in the earth. They are there sought after by the negroes, who eat them boiled in water, or roasted in the ashes. The seed is of the size of the little finger, with the taste of an almond, but with a flavour of dry pitch, at first unpleasant. An oil equal to that of olives, which does not grow rancid, may be obtained from it, by pressure; and a bushel of the seeds, which, in the year 1768, were valued at only eight pence, produced a gallon of oil. Philosophical Transactions for 1769.

GRU'MUS, (from *garam*, a clot, Hebrew,) a portion of the coagulum of blood or milk.

GRU'TUM. Decorticated unbruised oats. GROATS.

GRY'PA. An ointment described by N. Myrepsus.

GRY'PHIUS PES, (from *γρυπῶν*, to incurvate). An instrument mentioned by Parey for extracting a mole from the uterus, bent like an eagle's talons; the griffin, from which it is denominated, is the appellation of a culture.

GRY'PHUS. See ADAMAS.

GRYPO'SIS, (from *γρυπῶν*, to incurvate,) an incurvation of the nails.

GUA'BAM. A sweet cooling fruit which grows in the West Indies. See Raii Historia.

GUACA'TANA; *scrophularia Indica*; is a plant which grows in New Spain, and which eases the piles, in the form of a cataplasm (see Raii Historia); but it is unknown to the systematic botanists.

GUA'CU. See CEBIPIRA BRASILIENSIBUS.

GUAIA'BARA. A tree that grows in Hispaniola; the Spaniards call it *uvifera*; the leaves are large, and used as paper. *Cocoloba uvifera* Lin. Sp. Pl. 523.

GUAI'ACUM, (Indian). *Guaiacum*, *hagioxyton*, *lignum benedictum*, *vita lignum*, *palus* and *palma sancta*, *euonymo adfinis occidentalis*, *ibirace*, &c. The darker kind the Americans call *hiacan*, or *huiacan*; the yellowish they call *hoaxecan*; *guaiacum officinale* Lin. Sp. Pl. 546.

COMMON GUAIA'ACUM, OR POCKWOOD.

This wood was introduced into Europe early in the sixteenth century from Jamaica, Mexico, and the Antilles. It is brought over in large pieces, each weighing from four to five hundred weight, hard, compact, and so heavy as to sink in water, of a pale yellowish colour without, but black, of a deep brown, or marbled, within. It hath little or no smell, except when heated, and then its odour is slightly aromatic. When chewed it is slightly pungent, a quality which resides in its resin, and which it yields, in some degree, to water by boiling, but wholly to spirits.

Of the bark there are two kinds, one smooth, the other unequal on the surface: both are weaker than the wood. In the choice of this medicine, the freshest, most ponderous, of the darkest colour, and the largest pieces are preferred; and, as the finer parts are apt to exhale, they should be rasped only when used.

The wood was first introduced into Europe as a remedy for the venereal disease; and, as it warms and stimulates, promotes perspiration and urine, proving occasionally a gentle purgative, it assists the operation of mercury. When the excretory glands are obstructed, the vessels flaccid, the habit cachectic, in many cutaneous and catarrhal complaints, female weaknesses, in gouty and rheumatic disorders, it is often useful. The hectic fever, which sometimes follows a salivation, yields to a decoction of the woods. Guaiacum seems to stimulate the exhalent vessels more than the heart and great arteries; and is consequently safer than those which act more powerfully on the sanguiferous system. It is of course esteemed more effectual than other sudorifics in the lues venerea, in all cases of rheumatism, perhaps in gout.

A long use of this medicine hath been supposed to produce a yellowness of the skin. In thin emaciated habits; in an acrimonious state of the fluids; in hot bilious habits, and where the fibres are very tense, it is suspected to be injurious.

Three ounces of the wood, or four ounces of the bark, may be boiled in ℥ iv. of water to ℥ ij. and if a little liquorice is added to the latter end of the boiling, it will

abate the disagreeable pungency of this medicine, which affects the throat in swallowing. Of this decoction at least half a pint should be taken in a day.

If the thin shavings of guaiacum are distilled in a retort, at first an almost purely watery fluid arises; on increasing the fire, an acid, reddish, empyreumatic liquor passes over, with a little fluid reddish oil, and much air is separated: the residuum is a coal. A pound of guaiacum wood, distilled on an open fire, gave ℥ iii. ss. of acid, and ℥ i. ss. of empyreumatic oil.

The extract of guaiacum, soft and hard, is prepared by boiling ℔ i. of guaiacum shavings in a gallon of water until half the liquor is wasted, repeating the operation by adding the same quantity of fresh water to the same shavings four or five times. The several decoctions passed through a strainer, are to be mixed and inspissated; adding, when the aqueous parts are almost exhaled, a little spiritus vini rectificatus, that the whole may be reduced into an uniform tenacious mass. This extract is called soft when of the consistence of a mass for pills, and hard when it can be powdered. The spirit is added at the conclusion of the boiling, that the resinous part may be perfectly mixed with the gummy. The harder extract is an excellent errhine.

The resin of guaiacum is prepared in the same manner as the resin of JALAP, q. v. and is the only active part of this wood: it is obtained pure by means of rectified spirit of wine, both from the wood and the gum, and is procured by wounding the bark in different parts of the body of the tree, from whence it exudes copiously. This natural resin, which is exported, is never pure; and about ℥ xii. of pure resin is obtained from ℥ xvi. of what is styled gum. This is partly accounted for by its being sometimes procured by boring billets of the wood longitudinally, and then burning them at one end, while the resin exudes from the other. It is also occasionally obtained by boiling the chips in water and common salt.

This gum is of a brown colour, partly reddish, often greenish, brittle, having a glossy surface when broken, of a pungent taste, affecting the tongue and palate in the same manner as the wood. It is chiefly brought in irregular masses, of a dusky green colour: that in the form of drops is the best, but rarely met with.

In choosing the gum, those pieces which have slips of the bark adhering to them, and that easily separated from them by percussion, is the best. When held against the light it is transparent, breaks with a smooth uniform shining fracture, of a bluish green colour. It is fusible in a moderate heat, but not softened by the heat of the fingers; insoluble in water, but soluble in alcohol; without smell or taste, but on hot coals diffusing an agreeable odour. When the powder is swallowed, it occasions a very painful burning and pricking in the throat.

Neumann assures us, that a composition of colophony and balsam of sulphur is imposed on the unwary for the true gum; but the cheat is easily detected, by exposing each to a due degree of heat, by which the odour of the false is perceived to be different from that of the true.

The wood and resin only are in general use as medicines; and as the efficacy of the former is supposed to be derived merely from the quantity of resinous matter which it contains, they may be considered indis-

criminally as the same medicine. Of the gum, or extracts, the dose may be from gr. v. to ℥ i. but in the latter dose it is often actively cathartic. It should be combined with a fluid by means of an egg, or some mucilage, as it is otherwise uneasy in the stomach. Indeed, if given in the form of an clectuary or bolus, a similar medium is necessary.

Balsam of guaiacum consists of gum. guaica. ℥ i. balsamum Peruv. ℥ iij sp. vini rect. ℥ i. ss. It was formerly called *polychrestum*; and from one to three drachms were given every night and morning in milk, or any convenient vehicle.

Tincture of gum guaiacum, commonly called the volatile tincture, is a solution of four ounces of the gum in a pint and a half of the compound spirit of ammonia. Pharm. Lond. 1788.

The dose is from a small tea spoonful to a large table spoonful two or three times a day, and it is very conveniently given in milk, though a proportion of the tinctura opii should be added, to prevent the larger dose from purging. Dr. Dawson frequently directs the latter dose with great advantage in rheumatic and arthritic complaints, in which cases, and against palsies from lead, he considers it almost as a specific. It should not, however, be given while any inflammatory diathesis remains.

See Raii Historia Plantarum; Lewis's Materia Medica; Neumann's Chemical Works; Cullen's Materia Medica.

GUAI'ANA CORTEX. See SIMAROUBA.

GUAJA'CANÁ, *diospyros, faba Græca latifolia, pseudo lotus; diospyros lotus* Lin. Sp. Pl. 1510. It is not much known; but its leaves and fruit are astringent.

GUAJA'VA. The *guáva, guajábo; psidium pomiferum* Lin. Sp. Pl. 672. The name of a tree in the West Indies, whose fruit is cooling and moderately astringent; the root is also astringent. See Raii Historia.

GUA'O. *Comocladia dentata* Lin. Ed. Wildenow, vol. i. p. 189. A West Indian tree, called *thetlatian*; its effluvia are so acrid as to be injurious to those who sleep under it. It has the odour of dung, and its juice is so black that it cannot be washed out of linen.

GUAPARAI'BA. The MANGROVE TREE of the West Indies; *mangle, and paletuvier*. The mangrove tree of the East Indies appears to be the *rhizophora gymnorhiza* Lin. Sp. Pl. 634; that of the West, the *g. mangle* Lin. Sp. Pl. 634. If the root is split and toasted, then applied to the punctures made by the poisonous fish called *niqui*, it is said to cure. See Raii Historia.

GUARE'RVA-O'BA. See CUCUMIS AGRESTIS.

GUARIRIGUIMY'MIA. *Bignonia pentaphylla* Lin. Sp. Pl. 870. A shrub in Brasil, like a myrtle, whose seed is supposed by Lemery to destroy worms.

GUA'SSEM. Certain black scorbutic spots mentioned by Avicenna.

GUATIMA'LA. See INDICUM.

GUA'VA. See GUAJAVA.

GUIDO'NIS BALS. See ANODYNUM BALS.

GUILA'NDINA MOR'INGA. See NEPHRITICUM LIGNUM.

GUILTY-I'BA. A tree growing in Brasil, and bearing the fruit called *guity coroga*, which contains a stone as large as a goose's egg, the kernel of which is astringent. The tree is not known to scientific botanists.

GU'LA, (from *γενομαι, to taste*). See CESOPHAGUS.

GU'MA. See ARGENTUM VIVUM.

GU'MMA, (from *gummi, gum*, plur. *gummata*, from the resemblance of the contents to gums,) is a tumour arising from the substance of a bone, so soft as to yield to the finger. As they increase in hardness, they are progressively styled *tophi, nodi, and exostoses*. In venereal cases, such tumours often happen on the head, and even in the middle of the hardest bones, apparently produced by an obstruction, and probably a dilatation, of the interstitial vessels raising the incumbent laminae. A softness of the bones sometimes succeeds abscesses of the adjacent parts, and sometimes the seat of the disorder is in the substance of the bone, as in the lues venerea; but guminata have, however, been discovered, when no adequate cause could be observed. An acid has been suspected in the blood, or perhaps the phosphoric acid of the bones may be in excess. See Petit on Diseases of the Bones. LUES VENEREA. Bell's Surgery, vol. v. p. 541.

GU'MMI, (*tsamah*, pronounced *ghamah*; Hebrew,) GUM, *gisisim*, is a concrete vegetable juice, of no particular smell or taste, viscous and tenacious when moistened with, and wholly soluble in, water; insoluble in alcohol or in oils; burning in the fire to a black coal, without melting or inflaming, and not volatile in the heat of boiling water.

The true gums are gum arabic, tragacanth, and senega: the gum of cherry and plum trees: the others contain a proportion of resin.

The virtues of gums are those of mucilages in general, which are only gums with a proportion of water. When the ancients used the word *gummi*, or *commi*, without any epithet, they meant gum arabic. The Κομμὶ λευκόν, (Hippocrates De Morbis Mulierum,) is the same.

GU'MMI ARA'VICUM, called also *acanthinum; gum lamac; gum Thebaicum and Serapionis*, GUM ARABIC, and the true GUM ACACIA. It exudes from the Egyptian acacia, or thorn tree, whose fruit affords the inspissated juice of that name. *Mimosa nilotica* Lin. Sp. Pl. 1506. (See ACACIA.) It is brought from Turkey in small irregular masses, of a clear whitish or very pale yellow colour.

Though insoluble in spirit, and in oil, yet, when formed into a mucilage, it is miscible with both, and with resins rendering them miscible with water. Dr. Grew first taught us to mix essential oil with water by means of gum; and in the London Medical Observations and Inquiries, vol. i. we find that oils, both expressed and distilled, resins, and balsams, may, by the same means, be mixed uniformly with water or with spirit. Alkaline salts, both fixed and volatile, though they render pure oil miscible with water, prevent the mixture of gum with oil. Acids do not in the least prevent the effect of gum in combining oils with water.

Animal glues very unlike vegetable gums are more nutritious, and apt to become putrid; and they will not combine oil with water. In a chemical view their difference is very great; those of the animal kind are changed by fire into a volatile alkaline salt, and a fetid oil; the vegetable into an acid liquor, and a very minute portion of oily matter, considerably less fetid than the former.

Gum arabic is glutinous and demulcent; consequently useful in tickling coughs, diarrhoeas, hoarseness, in car-

dialgia, when from any oily aliment, and in almost every disease of the urinary organs. In dysuria the true gum arabic is preferable to the other simple gums. Though its action has been supposed not to extend beyond the glottis and the alimentary canal, it is certainly conveyed with little change to the kidneys; and, when used in moderate quantities, even checks the urinary discharge. To be effectual as an internal demulcent, two ounces a day should be, at least, taken. Dr. Hasselquist informs us, that a caravan, whose provisions were exhausted, found it very nutritive.

One ounce of gum arabic renders a pint of water considerably glutinous; but for mucilage, one part of gum to two parts water is required, and for some purposes an equal proportion will be necessary. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

GU'MMI FU'NERUM. See BITUMEN.

GU'MMI GU'TTA, and AD PODAGRAM. See GAMBONIA.

GU'MMI RE'SINA LU'TEA. New Holland has furnished two new medicines; the red and the yellow gum. The first is astringent, and not unlike the kino described in the following article. The yellow is not very dissimilar; but the plant from which each is procured has not been reduced to its place in botanical systems.

GU'MMI RU'BRUM ASTRI'NGENS GAMBIE'NSE. The red astringent gum from GAMBIA; *Kino*; *sanguis draconis officinalis*, or the finest and true DRAGON'S BLOOD. Dr. Oldfield calls it true *gum Senegal*. In the inland parts of Africa it is called *faou de sangue*: *faou* is said to be a corruption of *palo*, *wood*; and, with the addition of *sangue*, to be the name of a tree in the inland parts of Africa which produces it.

Gum kino is very friable, easily breaking between the fingers; without smell, of an opaque, dark, reddish colour, appearing almost black in the mass, and, when powdered, of a deep lateritious red. In chewing, it first crumbles, then coheres slightly, and seems soon to dissolve, with a very astringent slightly sweet taste.

It differs from the red lumps of the common gum Senegal in being much more brittle; and from the dragon's blood in its affinity to water; and from both in its stypticity when tasted. It dissolves both in spirit and in water; each taking up about two thirds of the whole.

This gum seems useful in many disorders from laxity, as in chronic diarrhœa, leucorrhœa, and mœnorrhagia. It contains a larger proportion of gum than any other astringent drug, and, joined with alum, in the proportion of one part to three, (as in the *pulvis stypticus*, Ph. Edin.) is considered to be one of the most powerful astringents which has been employed. In a liquid form, however, the kino is said by Tromsdorff to decompose the alum; but this effect appears to depend on some accident, as the experiment does not always succeed. Cullen's *Materia Medica*; London *Medical Observations and Inquiries*, vol. i. p. 358, &c.

GU'MMI SENEGALE'NSE, *gum Senega*, and *gum Orientale*, is brought from the island Senegal, on the coast of Africa, and is said to be the production of the tree which affords the gum arabic.

This gum is generally in larger and darker pieces than the gum arabic, and rough on the outside: the gum arabic also is dry and brittle, but the Senega

clammy and tenacious. The clearest pieces are sold for gum arabic, and their qualities are nearly similar; but the gum Senega is certainly more adhesive.

GU'MMI TRAGACA'NTHA, (from *τραγος*, a goat, and *ακανθα*, a thorn, because its pods resemble a goat's beard,) *adraganth*, and *dragantum*; GUM DRAGANT, or TRAGACANTH. This gum exudes from a prickly bush, which grows in Crete, Greece, and Asia. *Astragalus tragacantha* Lin. Sp. Pl. 1073. GOAT'S THORN, or MILK VETCH. It is chiefly brought to us from Turkey in irregular lumps, or in long vermicular pieces. In Candy it begins to exude about June, and is more or less pure and white, according to its accidental mixture with dust. That which is white, light, smooth, and transparent, in vermicular striæ, of a sweetish taste, and without smell, is preferred. A yellowish or brownish colour is no mark of imperfection or impurity.

It differs from all other gums in giving a thick consistence to a larger quantity of water, probably from being insoluble in this fluid, which it slowly imbibes in a large proportion, swells into a considerable bulk, and forms a soft, but not liquid mucilage. On the further addition of water a fluid solution may be obtained by agitation, but the liquor is turbid; and, on standing, the mucilage subsides, the limpid water on the surface retaining little of the gum. It is more powerful as a mucilage than other gums, but not as a demulcent, though it softens and thickens acrid humours.

The *pulvis è tragacantha compositus* of the London college is made in the following manner: R. *Tragacanthæ* in pulverem tritæ, gum. arabici, amyli, singulorum $\frac{3}{i}$ ss. sacchari purificati $\frac{3}{ij}$. simul in pulverem terc. Ph. Lond. 1788.

It is mild, emollient, and useful in tickling coughs, and supposed to mix oils and resins more smoothly than the gum arabic. See Lewis's *Materia Medica*; Neumann's *Chemical Works*; Cullen's *Materia Medica*.

GUMMO'SÆ PI'LULÆ, (from *gummi*, *gum*). See ASAFETIDA.

GUMMO'SUM ELECTA'RIMUM, (from the same). See DYSURIA.

GURGEA'TIO, (from *gurgēs*, a stream of water). See SUDOR ANGLICUS.

GURGU'LIO, (*γουργαλιον*, from *gargarah*, the throat, Hebrew). See UVULA: the insect also called a *weevil*.

GUSTATO'RII. See HYPOGLOSSI EXTERNI.

GUSTATO'RIOUS, (from *gusto*, to taste,) the name of the third maxillary branch of the fifth pair of nerves.

GUSTE'RANAX. See BITHNIMALCA.

GU'STUS, (from *γινωσκει*, to taste). The TASTE. Upon the tongue, towards the apex and sides under the skin, are obtuse papillæ of various figures; prominent in the tongue of a living person, when applied to the object of taste; but not discovered in the dead body. They rise from the nervous substance which covers the muscular flesh in the tongue, pass through the perforations of the corpus reticulare, as in the skin, and are covered with small vaginæ, formed by the exterior membrane of the tongue. These vaginæ are seemingly porous, that the substance tasted may, by pressure, be applied to them. Bellini has shown that these papillæ only are the medium of taste; and that the other parts

of the mouth, tongue, and palate, contribute nothing to it, except as resisting surfaces to assist the application. It is, however, highly probable that the back part of the palate is also sensible of the impression which conveys the taste.

It hath been generally said, that salts are the true objects of taste; and that the diversity of taste is owing to the different figures which are natural to salts: but Haller, on the contrary, asserts, that the reason of the diversity of flavours seems to reside in the intrinsic fabric or apposition of their elements, which do not fall under the scrutiny of the senses. In general, he thinks whatever contains less salt than the saliva is insipid; but that the nature or disposition of the covering with which the papillæ are clothed, together with that of the juices, and of the aliments lodged in the stomach, have a considerable share in determining the sense of taste; so that the same flavour does not equally please or affect the organ in all ages alike, nor persons of the same temperatures, nor even the same person at different times. In fact, the sense of taste is more closely connected with the state of the stomach than is generally supposed; and the languor or indisposition of that organ destroys or depraves the sense of taste. Other nervous affections have a similar effect. In fevers the taste is deprived or lost, and the substance of the papillæ, or of their vaginæ, seems to be organically changed; for with whatever care the tongue is cleaned, it never attains a healthy appearance.

In general, the taste determines what aliment is salutary; for the most part, whatever offends the taste is injurious in the stomach. See Haller's Physiology, in his Lecture of the Taste.

GU'TTA, (from *χρῶ*, to pour out). A DROP; *alunsel*. Drops are an uncertain form of administering medicines; and, where great exactness is necessary, they should not be prescribed. The shape of the bottle, or of its mouth, from whence the drops fall, as well as the consistence of the fluid, occasions a considerable difference in the quantity administered.

Gutta is also a name of the apoplexy, from a supposition that its cause was a drop of blood falling from the brain upon the heart.

GU'TTA GA'MBA. See **GAMBOGIA**.

GU'TTÆ NI'GRÆ. The black drops, occasionally called the Lancashire or the Cheshire drops, is a secret preparation of opium, more active than the common tincture, and supposed to be less injurious; as seldom followed by headach. One drop of this medicine is equal to about two and a half of the tincture of opium. We are informed by Dr. Cassells, that there are two preparations in use under this title. In the first, five ounces of purified opium, with pimento and cinnamon, of each two drachms; saffron and Seville orange peel, of each one drachm; are digested for a week in rectified spirit of wine, which is separated from the fæces by pressure. In the other, four ounces of opium are digested for three weeks in as many pints of the juice of quinces or verjuice, to which saffron, cloves, nutmeg, and cinnamon, of each an ounce, are added, and the digestion continued another week. Neither appears to us the real preparation; but we shall resume the subject in another article. Vide **OPIUM**.

GU'TTA OPA'CA. See **CATARACTA**.

GU'TTA ROSA'CEA, according to Dr. Cullen, is syno-

nymous with *varus*, and *bacchia*; and these are placed as varieties of the *phlogosis phlegmone*. It is sometimes called simply *rosacea*, from the little red drops, or fiery tubercles, dispersed about the face and nose; *rubedo maculosa*, *Ionthos*, *butiga*, *gutta rubea*, *ruonia*, and *rosea*. Nicholas Florentinus distinguishes three degrees of it, viz. 1. *rubedo simplex*, seu *facies rubra*; 2. *pustulosa*; and, 3. *ulcerosa*.

The cause is supposed to be in the liver, and this idea is supported by observing, that often on the disappearance of fiery pimples in the face, an indurated liver and a dropsy follow; on the contrary, disorders of the liver are sometimes relieved by eruptions in the face, so that repellents should be carefully avoided. Whether it be the cause or effect of a diseased liver, those addicted to spirituous liquors are most subject to this complaint; but the most abstemious are sometimes affected with it, by suddenly drinking a draught of cold water when they are hot, or by any partial suppression of the perspiration. The disease is peculiarly obstinate, and often resists every attempt to relieve it; nor will the eruptions disappear till the constitution is completely ruined.

In general, a temperate regimen is proper; but if the patient is accustomed to generous diet, a sudden alteration is not advisable: violent exercise should be avoided; and the mind kept as calm as possible. Scarborough water is generally esteemed very useful; spirits, spices, and every thing but the mildest food, should be avoided.

Practical writers abound with variety of topical applications; but great caution is required in their use. The hydrargyrum nitratum, if cautiously employed, is sometimes safe, and is the medicine called the golden ointment.

Internally, mercurial deobstruents, with antimonials; saline, acidulous, and ferruginous waters, are useful. The decoction of sarsaparilla, of mezercum, or of ether, with that of the elm bark, or the root of the water dock, adding as much of any neutral salt as will keep the bowels loose, are the best assistants of the mercurials and antimonials. See Heister's Surgery; Turner's Diseases of the Skin; Medical Observations and Inquiries, vol. i. p. 189.

GU'TTA SERE'NA. (See **AMAUROSIS**.) On recurring to this article, we perceive that we omitted to mention Mr. Ware's very ingenious remark, that it may be sometimes occasioned by a dilatation of the circulus arteriosus, that circle which surrounds the sella turcica, and which on the fore part passes over the optic nerve. The anterior arteries are branched from the carotid; but others rise soon after, which, passing backward, join the basilar artery, and form the posterior portion of the circle, which lies over the nervi motores oculorum. This cause probably produces the disease when it is accompanied by an inability of moving the upper eye lid; and we can easily suppose that it may affect the optic nerve, without producing any change on the motory nerves, as the larger portion of the blood may be carried off by the anastomosing branches of the basilar artery.

We need scarcely apologise for omitting the singular fancy of Richter, who attributes gutta serena to infarcted viscera, and combats it by deobstruents and antispasmodics.

GUTTE VI'TÆ. BALS. TRAUMATICUM. See BENZOINUM.

GUTTÆ ANGLICA'NÆ. A famous remedy of Dr. Goddard, which, we are assured by Lister, was only the spirit of raw silk rectified with oil of cinnamon. The secret was sold to Charles II. for the enormous sum of 5000*l.*

GUTTA'LIS. See ARYTENOIDES.

GUTTE'ATA, (from *goutte, the cramp*). Castellus informs us that the word *goutte* in French signifies *convulsion*; hence the name of a preparation called *pulvis ad guttetam*, which consisted of dittany, human skull, contrayerva, &c.; in general equal parts of peony and valerian roots are only mixed. It was originally an invention of Riverius, and often called *epileptic powder*.

GUTTUR, (from *γυω, to pour out*). The THROAT; *brochthus*. See BRONCHOCELE.

GUTTURA'LIS ARTERIA, (from *guttur, the throat*). The first considerable branch of the external carotid is the superior guttural, which arises where it parts from the internal, and runs to the thyroid gland, to the muscles, and other parts of the larynx or pharynx, hence called *laryngea*.

The inferior guttural artery is the TRACHEALIS ARTERIA, q. v.

GUTTURA'LIS VE'NA, trachealis. The right goes from the under part of the bifurcation above the mamma of the same side, and sometimes from the subclavian. The left from the left subclavian near its origin.

GUTTURIFO'RMIS CARTILA'GO, (from *guttur, the throat* and *forma, likeness*). See ARYTENOIDES.

GYMNA'STICA. GYMNASTICS; exercises of the body which were proposed for the restoration and preservation of health, and for the cure of diseases. They were of Greek origin; and are so called from the word *γυμνος, naked*; for they were performed by naked men in the public games. These exercises were originally designed to accustom the youth to feats of activity and strength. War was a laborious occupation from the weight of the armour, and strength must be acquired by exertion, and supported by constant exercise. The games were consequently connected with their religion, and victory in them was politically rendered an object of the highest importance.

—————Palmaque nobilis
Terrarum dominos evehit ad Deos.

The gymnastic art had attained no considerable degree of perfection in the days of Homer, as we find from the description of the games at the funeral of Patroclus. It was introduced, however, into medicine only about the time of Hippocrates, or rather a little before his era by Herodicus, probably his father. The gymnastics of the warriors were too violent for the diseased, or even for the preservation of health in those not naturally strong; and Hippocrates, in his work on

regimen, speaks of exercise in general, of walking, of races either on foot or horseback, leaping, wrestling, the corycus, or exercising the suspended ball, with the usual additions of unctions, frictions, and rolling in the sand. Boxing, the pancratiæ, hoplomachia, running, quoits, the exercise of the ball, hoop, and javelin, driving the chariot, and swimming, seemingly required too great exertion to be admitted into the medical department; though walking, vociferation, recitation, and holding the breath, seem to have been among the medicinal gymnastics. Hoffman mentions fifty-five kinds of medicinal exercises, which it were tedious to enumerate. *Vide in loco*.

The Ægyptians considered gymnastics not necessary; they thought that by them a genuine health was not procured, but in its stead a short-lived strength, highly dangerous to young people. See Hieronymus Mercurialis de Arte Gymnastica Fabri Agoniston; Fuller's Medicina Gymnastica; Hoffman de Athletis Veterum, vol. v. p. 377, &c.

GYMNOSPE'RMIA, (from *γυμνος, naked*, and *σπέρμα, seed*). The name of the first order in the class *didynamia*, in Linnæus's system, comprehending those plants which have four stamina; of which the two middle are shorter than the two outer ones, with a ringlet flower, succeeded by four naked seeds.

GYNÆ'CIA, (from *γυν, woman*). See LOCHIA and MENSES.

GYNÆ'CIUM, (from *γυν, a woman*). A SERA-GLIO; an appellation of antimony, and the *fudendum muliebri*.

GYNÆCOMA'STON, and **GYNÆCOMA'STOS,** (from *γυν, a woman*, and *μαστός, the breast*). An enormous increase of the breasts of women; or a man whose breasts are large like a woman's.

GYNÆCOMY'STAX, (from *γυν, a woman*, and *μυστάξ, a beard*.) the hairs on the female pudenda.

GYNA'NDRIA, (from *γυν, a woman*, and *ανδρ, a man*). The name of the twentieth class in the Linnæan artificial system, containing all plants with hermaphrodite flowers, which have the stamen growing upon the style; or else an elongated receptacle, bearing both stamens and styles. This class has been considerably reduced by some modern reformers, and the plants referred to other classes.

GYNA'NTHROPOS, (form *γυν, a woman*, and *ανθρωπος, a man*). That species of hermaphrodite which partakes more of the female than of the male, opposed to that which partakes most of the male, called *androgynus*. These distinctions are groundless; for hermaphrodites are generally women.

GYNECA'NTHE, (from *γυν, a woman*, and *ακανθα, a thorn*; supposed to be the female briony, and also prickly). See BRIONIA NIGRA.

GYPSOPHY'TON, (from *γυψος, lime*, and *φυτον, a herb*; because it was supposed a lithontriptic). See PIMPINELLA ALBA GERMANORUM.

H.

H Æ M

H Æ M

HA'BA. See **FABA**.

HA'BASCUM. The name of a Virginian root which resembles a parsnip, and is a salutary food.

HABÆ'NA. A BRIDLE. The name of a bandage, for the purpose of keeping the lips of wounds together.

HABI'LLA DE CARTHAGE'NA. See **BEJUIC**.

HABI'TUS, (from *habeo, to possess*). **HABIT**. See **CONSUETUDO**.

HA'BITUS PLA'NTÆ. The habit of a plant; its outward general appearance.

HA'CUB. A species of *carduus*, the young shoots of which are eaten by the Indians, but the roots are emetic. *Gundelia Tournefortii* Lin. Sp. Pl. 1315, of which there are two varieties: the first grows in America, and the second in Syria. It is classed by Jussieu with the *cynarocephali*, and has the leaf of a *carduus*, the habit and juice of a *scolymus*, and the head of an *eryngium*.

HÆ'MA, (from *αιθω, to be hot*; from its heat). See **SANGUIS**.

HÆMAGO'GOS, (from *αιμα, blood*, and *αγω, to bring away*). The name of an antidote in Nicolaus Myrepsus, which was used for promoting the menstrual and hæmorrhoidal discharges.

HÆMALO'PIA, (from *αιμα, blood*, and *οπλομαι, to see*). A variety of the *pseudoblephsis imaginaria*, in which every thing seems of a red colour.

HÆ'MALOPS, (from *αιμα, blood* and *ωψ, the countenance*). The livid marks of sugillations in the face and eyes.

HÆMATAPO'RIA, (from *αιμα, blood*, and *πορειω, to put away*). A wasting from poverty of blood.

HÆMATEME'SIS, (from *αιμα, blood*, and *εμεω, to vomit*). See **VOMITUS**.

HÆMA'TIA, and **HÆMA'TION**. An epithet for *garum*, made of the intestines of fish macerated in salt.

HÆMATI'TES, (from its supposed virtue of stopping blood). It is called also **BLOOD-STONE**, *azedegrin*, *asedenigi*. When in flatish cakes, with knobs on the surface, the ancients called it *hæmatites*; when in long striated pieces, *schistus*; but they do not differ. The *terra sinopica* is also called *blood stone*. *Fer oxide hematite* of Haüy iv. 105.

Twenty-four parts of *hæmatites* yield nine of iron; but it often affords half its weight, and is found in Germany, France, Spain, and England. It is very hard,

of a dark red colour; but of a brighter hue when powdered. As it is very difficultly powdered, the *crocis martis*, or the *rubigo ferri*, may be substituted. See **Lewis's Materia Medica**.

HÆMATITI'NOS, (from *hæmatites*). An epithet of a collyrium in Galen, in which is the *hæmatites*.

HÆMATOCE'LE, (from *αιμα, blood*, and *κηλη, a tumour*). A species of false hernia in the scrotum, consisting of a collection of blood in the *tunica vaginalis*. It resembles, in appearance, an hydrocele, and the method of cure is the same. It most commonly follows hydrocele, and is occasioned by a puncture of the instrument, or sometimes by a natural hæmorrhage, in consequence of the support taken from the vessels by a discharge of the water. Blood in the *tunica vaginalis* is distinguished from water by its colour and weight. The tumour may be sometimes discussed by stimulant and astringent lotions; but the operation is generally necessary. If any vessel appears to discharge blood, and the application of alcohol, tincture of myrrh, or ether, applied by means of pledgets of soft lint, do not check the bleeding, the ligature must be employed. See **Celsus**; **P. Ægineta**; **Bell's Surgery**. vol. i. p. 482; **Pott's Works**, 4to. 1775; **White's Surgery**, p. 342.

HÆMATOCE'LE ARTERIO'SUM. See **ANEURISMA**.

HÆMATOCHY'SIS, (from *αιμα, blood*, and *χειω, to pour out*). See **HÆMORRHAGIA**.

HÆMATO'DES, (from *αιμα, blood*, and *ειδος, resemblance*; from the red colour of its flower). See **GERANIUM SANGUINARIUM**.

HÆMATO'LOGIA, (from the same, and *λογος, sermo*). The doctrine of the blood, or an account of its nature and properties.

HÆMATOMPHALOCE'LE, (from *αιμα, blood*, *ομφαλη, navel*, and *κηλη, a tumour*). A tumour in the navel, turgid with blood. If astringent and stimulating applications do not succeed in discussing it, the fluid may be evacuated by a puncture.

HÆMATOPEDE'SIS, (from *αιμα, blood*, and *πειδω, to leap*). **BLOODY SWEAT**; or the spurting of blood from a wounded artery.

HÆMATOPHLEBCE'STASIS, (from *αιμα, blood*, *φλεψ, a vein*, and *στασις, a station*), is a suppression of the impetuous current and intumescence of the blood in the veins. But, according to Galen, it sometimes means a full vein.

HÆMATO'XYLON CAMPECHIA'NUM, (from αιμα, blood, and ξυλον, wood; so called from its red colour). See CAMPECHENSE LIGNUM.

HÆMATU'RIA, (from αιμα, and ουρον, urine). See URINA.

HÆMOCE'RCHNUS, (from αιμα, blood, and κερχνος, noise). Blood brought up from the fauces, or the lungs, with a noise or rattling; sometimes bloody excretions discharged in a dry form.

HÆMO'DIA, (from αιμαδεω, to stupify). A painful stupor of the teeth, from acid and austere substances.

HÆMO'PTOE, (from αιμα, and πτωω, to spit up). See HÆMOPTYSIS.

HÆMOPTY'ICUS, (from the same): *Hæmotoricus*. A person who discharges blood from the mouth.

HÆMOPTY'SIS, (from αιμα, blood, and πτωω, to spit). A SPITTING OF BLOOD; *hæmoptoe*. By this term, however, is meant a bleeding from the trachea or the lungs; for blood from the nose and the stomach is often apparently spit. When from the veins of the lungs it is called *perirrhæxis*: but this can scarcely, in any case, be ascertained.

Dr. Cullen places this genus in the class *pyrexia*, and order *hæmorrhagia*, defining it a flushing of the cheeks; an uneasy sensation or pain, and sometimes heat, in the breast; a tickling of the fauces; a cough, by which blood of a florid colour, often frothy, is ejected by the mouth. He distinguishes five species:

1. HÆMOPTY'SIS PLETHO'RICA, when no external force has been applied, nor any cough or suppression of usual evacuation has preceded.

2. HÆMOPTY'SIS VIOLE'NTA, when from external violence.

3. HÆMOPTY'SIS PHTHIS'ICA, where emaciation and continued debility follow.

4. HÆMOPTY'SIS CALCULO'SA, when with the blood calcareous concretions are thrown up.

5. HÆMOPTY'SIS VICA'RIA, when from the suppression of some accustomed evacuation.

Passionate, weak, and slender people, with long necks and flat breasts, or a sharp carinated sternum, gibbous or otherwise distorted, and those who while young were subject to bleed at the nose, are most subject to an hæmoptysis.

An hæmoptysis may occur, 1. From an accidental rupture or a wound of the vessels; but if the vessels are small, the patient quiet, and no previous disease exists in the lungs, there is little danger; but if large, the danger is considerable. 2. From tubercles or small tumours of an apparently scrofulous nature, contracting the vessels of the lungs, and consequently increasing the impetus on the other vessels, which in such constitutions are usually weak. This kind usually ends in phthisis. 3. From an ulcer in the lungs, forced up by coughing, and mixed with phlegm or pus; in which case the danger is great, as some large vessel has probably been eroded. 4. By anastomosis: this is said to be without danger, and often to relieve women whose menses are suppressed; but the existence of an anastomosis is in this case doubtful. It is more properly metastasis.

Sometimes the bronchial artery is ruptured. If the orifice is small, the discharge soon ceases; for, by the stagnation of the blood in the cellular substance of the lungs, the artery is compressed, and the rupture closed:

this blood is sometimes absorbed, at others it excites inflammation, which terminates in suppuration. It then reaches the bronchiæ, and is by degrees spit up; but a hectic usually follows.

When the rupture happens in the pulmonary artery the discharge is sudden, and the blood more copious and florid than when from the bronchial artery; but without pain, and unmixed with phlegm. In this case the preceding symptoms are anxiety about the præcordia, difficulty of breathing, an oppressive undulatory pain about the diaphragm, flatulencies in the belly, a sense of heat in the sternum, salt taste in the mouth, coldness of the extremities, hoarseness, a dry tickling cough, &c. As these show a general stricture on the vessels, and a change in the balance of the circulation, so they are commonly the forerunners of a copious hæmorrhage. When the discharge is from the bronchial artery, its ejection is not sudden, and its appearance is blackish, and somewhat thick; though a frothy cough attends, there are a pain and heat in the breast, with a sense of weakness there, during the disease, sometimes with a fever, which abates with each discharge of blood, and returns at intervals when the hæmorrhage is stopped. Sometimes matter is mixed with, or follows after, the discharges. The distinction of these two cases is, however, difficult, and of little importance. It is of more consequence to ascertain whether the blood comes from the fauces, the nose, or the stomach. If from the fauces, either directly, or dropping from the nose, it is inconsiderable in quantity, and not *always* attended with any hawking; and though this is sometimes the case, the symptoms of hæmorrhagia nasi, or inspection of the fauces, will assist the distinction. Blood, however, seldom comes from the fauces, but in consequence of local inflammation or scurvy. When a discharge of blood is from the stomach, it is brought up by vomiting; but patients can seldom distinguish between these two operations. In general, when from the stomach, the quantity discharged *at once* is more considerable, it is mixed with the contents of the stomach, and not the mucus of the lungs; and nausea has generally preceded. The pulmonary blood is usually florid; that of the stomach of a darker colour. Complaints of the lungs preceding the discharge, will show that a doubtful hæmorrhage probably proceeds from that organ.

Spitting of blood, or rather the appearance of some blood with the sputum, is generally useful in pleurisies and peripneumonies; in the robust, a spitting of blood is not always dangerous, but in the tender and feeble the disease is seldom cured; if blood proceed from an ulcer, the event will be probably fatal.

The causes of hæmoptysis are those of hæmorrhage in general, viz. fever, with an alteration in the balance of the circulation, or increased impetus in consequence of obstruction; but this requires some elucidation. We have said, that, in the gradual evolution of the human body, the head is at first disproportionately large, and receives, for purposes we need not now explain, a large proportion of the vital fluid. In succession the chest expands, and receives in turn its additional quantity. Thus, in early youth, bleedings from the nose are frequent; we next find similar discharges from the lungs. When, therefore, a tendency to plethora exists, those vessels yield which are most fully distended in the different periods. Hæmorrhages from the lungs are,

however, more frequent from the second cause. Tumours, styled tubercles, as we have said, frequently contract the cavity of the chest, and occasion the most dangerous hæmoptysis; as from the increased impetus, which occasions the hæmorrhage, inflammation is induced, and a suppuration of an unkindly nature follows. If, from weakness, the vertebræ are distorted, the child, to relieve itself, bends on the opposite side, and by this double curvature greatly contracts the cavity. Tight ligatures round the chest, while the child is growing, equally prevent its expansion; and the mode of carrying children, by grasping them on each side of the sternum, produces the same effect. When we treat of hæmorrhages, we shall find that those styled active are attended with a febrile exacerbation, which, we have seen, destroys the balance of the circulation, and throws a large proportion of the blood on the internal parts. In such circumstances the occurrence of hæmoptoe is not surprising, when any of the predisposing causes, formerly mentioned, exist. Independent, however, of fever, the disease may happen from the contraction alone, since, in every situation, any considerable stricture, as we have seen (v. FEBRIS), or as we shall more fully show (v. INFLAMMATION), increases the action of the vessels a tergo; and should the slightest cause of increased general impetus or topical weakness concur, the disease must inevitably be produced. Whether any contraction of the bony covering of the chest has a tendency to bring on tubercles, has not been shown; but the very frequent consequence of tubercular consumption, from almost any hæmorrhage of the pulmonary vessels, seems to show either that this is the case, or that tubercles exist in almost every constitution, which, from dissection, appears not to be true.

These considerations lead to important consequences in the means of preventing hæmoptysis, and the consequent hectic. The first rule which they suggest is the propriety of guarding against every cause of increased impetus, by the mildest food, the gentlest exercise, and avoiding excess of every kind. Another is, the propriety of inducing some steady permanent discharge from the thorax, if any part of the chest appears particularly diseased. This is ascertained by pain, particularly felt on a full inspiration, or by the inability to lie on one side. The decubitus difficilis is a problem in pathology of no little intricacy; but, in general, in cases of this kind the patient *cannot* lie on the side affected; probably because the weight of the contents of the sound side contributes to check the very little action that remains. Whatever, however, becomes of the explanation, the fact is well established; and a blister, or a seton, can be continued on the side which is known, from this circumstance, to be diseased, without any inconvenience to the patient. If the disease cannot be discovered from this criterion, the blister should be placed on the sternum, near its lower part. In this place it will certainly contribute, though in a less degree, to take off inflammatory tension from every part of the thorax.

When hæmoptysis has come on, it must be combated by other remedies; and one of the most common, apparently the most useful, is generally bleeding. This, if preferred, should be actively employed; for small bleedings, frequently repeated, exhaust the patient instead of relieving the disease. We are confident, however, in

adding, that this remedy is used too frequently, and with too little discrimination. An active, plethoric young man, labouring under hæmoptysis, from excess, from strains, or accident, may be bled freely, and frequently. A weak, debilitated person, with a contracted chest, may, for a moment, be relieved; but the remedy, together with the disease, contributes to sink the strength, and the habit is soon established, which requires this assistant discharge. It must be remembered, also, that hæmoptysis is sometimes owing to the contraction of the chest with debility, and but little, if any, assistance from increased impetus. In this case the advantages of bleeding, though considerable, are temporary, and its disadvantages numerous; yet it is an indispensable remedy.

As a blister will prevent, so it will often lessen, pulmonary hæmorrhage; and is indeed a very unequivocal remedy, though we so often hear of the stimulus it occasions during its early action. Whatever it may be in other respects, we know from experience that it is not injurious in hæmoptysis.

Another class of remedies is more suspicious; we mean emetics. We need not repeat what we have said under that head; but would chiefly limit their use to active hæmorrhages from the lungs, after bleeding; though even in a very debilitated state we suspect they may be useful. In this, however, they have not been tried; and they are certainly, in such circumstances, precarious.

Sedatives, particularly those which repress the activity of the circulation, are highly useful. Of these the chief are nitre and digitalis, to which some others have been added.

Nitre, if taken early in this disorder, is much to be depended on. The following method is convenient and useful: R. Sal. nitri $\frac{z}{3}$ ss. conservæ rosarum $\frac{z}{3}$ iv. m. cap. q. n. m. major. 3tia. quaq. hora pro re nata. But this remedy is much more effectual when given in the coldest water, and swallowed while dissolving. Ten grains, in urgent cases, may be given every hour, or even more frequently.

Digitalis has not been employed so actively as the urgency of the disease seems to require; but it may be given every hour, increasing each time the dose by a quarter of a grain of the powder. Its worst effect will be that of vomiting, which we have no reason to dread. As nitre, in the way recommended, is only a form of cold, so cold drinks, recommended by De Haen, may be equally useful, except that the bulk, required to produce a sufficiently sedative effect, may be inconvenient.

Another sedative that has been employed is opium; but this has been avoided, as it is suspected of stimulating in its first operation. We have found it, however, an useful medicine, without the slightest inconvenience from the supposed effect.

Cicuta has not, we believe, been given in such circumstances; yet, as it acts with safety as a narcotic in consumptive cases, we should expect some advantage from it. The belladonna and tobacco, also, which powerfully affect the nervous system, may, in emergency, be tried. Tobacco in clysters often produces fainting.

A remedy employed freely in America, with much confidence, is a table spoonful of common salt dissolved in a very small proportion of water. This cannot, like nitre, act as a sedative; but probably operates as an un-

diffused stimulus on the œsophagus and stomach, which, by increasing the action of the vessels of their internal membranes, relieves the neighbouring organs, without increasing the impetus of the circulation. Does the vitriolated magnesia act in a similar way? It is undoubtedly an useful medicine in this disease, independent of its laxative powers. But gentle laxatives are always necessary to prevent the straining required for the evacuation of a costive motion, and to relieve every impediment to the circulation in the chylopoietic viscera.

Astringents, often relied on, are of little real utility. The bark is injurious; and, indeed, when we reflect that whatever constricts the fibres increases the disproportion between the capacity of the vessels and their contents, we must be satisfied that medicines of this kind are hurtful. Alum indeed is not without the suspicion of possessing a sedative quality, and kino is not manifestly an astringent. Yet each seems of little real utility in this complaint. In the passive hæmoptyses, astringents are apparently more proper, but even in these nitre is preferable; for in the lowest weakness of the animal actions, the heart and arteries often beat with the most inflammatory violence.

If the cough be troublesome, demulcents are necessary; and to these opium may be safely joined, even by those who dread its stimulus in other circumstances: but care must be taken that laxatives be interposed, lest an inconvenient and dangerous constipation should ensue. See Wallis's Sydenham. London Medical Observations, &c. vol. iv. p. 206; and Medical Museum, vol. ii. p. 257—259. Cullen's First Lines, vol. ii. p. 336, edit. 4.

HÆMORRHA'GIA, (from *αἷμα*, blood, and *ραῖα*, to flow). *Hæmatochysis*, and *sanguifluxus*. Hæmorrhages, though frequent diseases, are not among the most dangerous complaints to which the human body is subject, and are of importance only in their consequences; for a hæmorrhage, when in excess, occasions faintness, and, during the deliquium, the bleeding stops.

The first distinction of hæmorrhages is into active and passive. Dr. Cullen, limited by his system, has chiefly noticed the former; but the line is not, as we shall soon find, easily drawn, or fixed with accuracy. Active hæmorrhages are those attended with fever, which seem to depend for their existence on coldness and shivering, with the usual attendants, a quick pulse, and marks of a particular determination to the part from which the discharge will proceed. But "degree does not change even a species," according to the canon of the systematics; and often in the lowest state of debility, the legs are cold, the part affected peculiarly hot, and the pulse throbs with vehemence. If such hæmorrhages are active, they have no place in Dr. Cullen's system. As a general outline, the distinction will, however, hold with sufficient accuracy, and we shall soon pursue it.

Another distinction is into accidental, and vicarious or critical hæmorrhages. The first are only to be styled diseases. When any discharge has been suppressed, blood is often poured from other vessels without any injury, except perhaps when the delicate organization of the brain is injured by it. Vicarious bleedings from the lungs are seldom dangerous; and from the stomach and intestines are only for a time inconvenient. But in the brain we cannot always limit the new discharge

so as to prevent injury from compression, though in many cases the blood has been absorbed without any permanent disease. Critical discharges also in the brain are dangerous; nor is it impossible that these or vicarious bleedings in the lungs, if violent, may not occasion at once suffocation.

Active hæmorrhages we must then consider as febrile diseases of an inflammatory kind. They are defined by Dr. Cullen pyrexia, with an effusion of blood, independent of external violence; and the blood drawn having an inflammatory appearance. Active hæmorrhages chiefly occur in full plethoric habits, most frequently in the spring and in the early months of summer, before the warmth of the air has relaxed the external vessels. Previous to the fever which ushers in the discharge, some general fulness and uneasiness are felt, with a load on the parts from whence the hæmorrhage will flow. The topical heat, swelling, or itching, is sometimes considerable. A short rigor which follows is relieved by the usual heat, and the hæmorrhage soon comes on during this hot fit. After some time the discharge and the fever both cease; but every spontaneous hæmorrhage has a tendency to recur, and if this recurrence happens more than one, after a stated time, a habit is formed which is with difficulty overcome. These very marked appearances do not always occur; but traces of these symptoms may be often distinguished even in the most debilitated states.

The remote causes of hæmorrhages are not always those of plethora. The most plethoric states in a robust constitution are not peculiarly attended with these discharges; and, on the contrary, extenuated habits are occasionally subject to them. The principal remote causes of active hæmorrhages are, an alteration in the balance of the circulation, or a want of energy to propel the fluids to the surface. The immediate cause is the increased impetus of the blood in the hot fit, which is produced by the distended vessels, and the effort excited to conquer the resistance. The vessel ruptured is in general one constitutionally weaker than any other.

Persons subject to hæmorrhage are usually those of an irritable, delicate constitution, sometimes the weak and exhausted. Violent exertions, at particular periods of life, will occasion them in every habit. Hæmorrhages are in general most violent in the full and strong; but more permanent in the weak and irritable. The reason is, that in such cases the red globules and the gluten are chiefly discharged, on which the strength greatly depends. Fainting therefore soon comes on, from the depletion of the arteries. In the weak the lesser vessels yield, and a less proportion of these parts of the blood is discharged. The evacuation contains chiefly the serum coloured only with the red globules. This is in a great measure the case where the hæmorrhage depends on a want of energy in the arterial system to propel the fluids to the surface; and the attendants are surprised to find that such considerable discharges can be borne, when in reality a very small portion consists of the nutritious fluids.

The repetition of hæmorrhages is connected with the causes producing an irregularity in the balance of the circulation, generally arising from the predominating energy of some particular part of the arterial system. The plethora soon returns, for generally the appetite is more keen; the digestive and assimilatory functions

always proceed with augmented vigour, while the secretions are for a time retained. The quantity is in this way soon restored, but the quality is gradually deteriorated. The fluids are thinner; for though water can be easily supplied, the formation of the red globules, of the gluten, and the fibrin, is not the work of a short period, and it proceeds slowly in proportion to the debility induced. The progressive fulness of the vessels of different organs, at different periods of life, we have already explained, and of course the successive discharges from the nose, lungs, and liver, hæmorrhoidal and urinary vessels. We may resume the subject, at some length, under the article HÆMORRHOIDES.

The causes which particularly favour the occurrence of hæmorrhage are: 1. External heat, which is said to rarefy the blood: but the blood is by no means an expansile fluid; and the swelling of the veins, in warm weather, alleged as an argument of its expansibility, is owing to the diminished resistance of the integuments. Sauvages and Haller inclosed blood in a thermometrical tube, and found that in the heat of boiling water it did not dilate $\frac{1}{200}$ part of its bulk. When, therefore, heat assists the production of hæmorrhage, it is rather by diminishing resistance, and increasing the irritability, which disposes to irregular action. 2. A sudden diminution of the weight of the atmosphere is said to have the same effect, and the facts adduced in its support are the bleedings from the lungs in ascending high hills. Later experience seems not to have confirmed this opinion, but to have attributed the hæmorrhage to the difficulties of the ascent, in lungs previously weak, since the accident is chiefly confined to such habits. 3. Violent exercise and violent passions certainly contribute to the production of hæmorrhage, particularly exercise of some organs, as of the voice, in producing hæmoptysis. 4. Ligatures, on particular parts or postures favouring a particular determination of the fluids. 5. Cold, particularly if applied suddenly to the lower extremities.

The first question to be considered when we are to speak of the *cure of hæmorrhages* is whether they are to be left to the regulations of nature, or be relieved by art. Dr. Stahl and his followers thought discharges of blood owing to the exertions of nature to remove an habitually plethoric state, and that when the vessels were sufficiently depleted the wound would close. We have admitted that when faintness came on, the hæmorrhage would cease; but it is highly proper not only if possible to prevent the occurrence, but to diminish or check the discharge. We cannot allow that nature, if all powerful, is all wise. If a person is plethoric she will sometimes discharge the load on the brain, sometimes on the lungs, where immediate death may ensue, instead of the stomach, where the blood would not be injurious. She does not when the plethora is removed prevent its recurrence, but stores up fluids for a return of the disease. In short, as in many other situations, nature must be superseded or checked in her operations, and hæmorrhages cured by art; for a recurrence, against which she has not provided, will occasion hydropic swellings; and in the lungs, her most common outlet, a consumption may be the consequence.

The chief foundation of what may be styled the hæmorrhage diathesis is plethora. It is necessary for various purposes of the animal economy that the arterial

system should be kept full; and even distended. The arteries are kept full, whatever be the quantity of fluids, by the elasticity of their external coat, and the contractility of the muscular: they are kept distended by that portion of the fluids necessary to counteract this elasticity and contractility. Fulness is therefore relative: when only in that degree which excites a proper tone it is salutary; when beyond, it is morbid tension. So necessary is a fulness of the vessels, that nature is always anxious to keep it to the proper degree, and even in excess. Plethora is consequently the most frequent morbid state, and hæmorrhages very frequent diseases. The means of relieving plethora, while constantly counteracted by nature, are not easy. Fluids evacuated either by nature or art are soon supplied, as we have said, by the stoppage of the secretions; and consequently *bleeding*, the most obvious means, is only a temporary relief. It is a suspicious one, as the quantity is soon restored; and it is injurious, as laying the foundation of a habit which cannot, with advantage be always obviated, or without danger neglected. It is, however, often absolutely necessary, to prevent fatal consequences; for suddenly to deplete will alone occasion that faintness to which the cessation of the discharge is most commonly owing. A more certain method of obviating plethora is by *diet*, and *increasing the excretions*. Though nature constantly keeps the vessels full by regulating the secretions, yet it depends on ourselves neither to fill the vessels rapidly with the most nutritious fluids, nor to keep them distended by inactivity. A light vegetable diet does not produce nourishment, either copious in quantity or rich in quality; and it prevents plethora, by being at the same time cooling and laxative. With this diet, moderate exercise is useful; and this is perhaps only contra indicated in hæmoptysis. Exercise, while it fills the vessels of the surface, whose united areas we have found to be considerable, promotes that insensible discharge which we have shown to be so highly salutary; and if conducted so as not to increase the vital heat, or accelerate the circulation, is highly useful. Another equally obvious method of avoiding plethora is by *laxatives*. These should be mild and gentle; of that kind which excites the discharge from the excretories, rather than that which stimulates the muscular fibres of the intestines. The neutral salts are particularly valuable in this view. Of the other evacuants we cannot speak highly as obviating plethora, though the topical ones which obviate partial plethora are of singular utility. These are cupping glasses, leeches, setons, issues, and blisters. Each acts by drawing the fluids to the surface: each by partially evacuating them. In this general view we need not enter into their comparative merits, and perhaps on the whole a preference cannot be easily assigned. Neither acts with rapidity, except perhaps the cupping glasses, and they are prophylactic rather than curative remedies.

A very effectual method of curing hæmorrhages is by moderating the impetus of the blood, on which they so greatly depend. The first medicines to be employed are *refrigerants*; and the most effectual of these is cold water, internally; occasionally with frequently repeated, rather than large, doses of nitre. The latter is a remedy of the greatest importance; an "instar omnium" in these complaints, especially when saline purgatives are interposed. External cold is equally useful;

to which we should add, avoiding the irritations of light, heat, noise, and agitation of either mind or body. It must be remembered, that, when we spoke of cold as a means of producing hæmorrhage, it was its sudden application, particularly to the extremities. In the cure of hæmorrhages, its continued application is chiefly necessary. *Sedatives* are equally useful with the same views; but opium is, as we have said, a doubtful remedy, as supposed to unite a stimulating power. Faintness, and even that degree of it produced by nauseating doses of medicines, checks the discharge; and, perhaps, that faintness induced by injecting tobacco smoke into the rectum may have the same effect. We are confident that the digitalis has been useful chiefly in this way.

Another method of curing hæmorrhages is by *derivation*. For this purpose, rubbing the feet with mustard, or putting them in warm water, has been advised; but the operation of the last remedy is suspicious: if the water is too warm, and the pediluvium too long continued, greater injury than advantage will result. To this head also the effects of blisters and cupping, without scarifications, may be, in part, referred.

Astringents have been liberally employed; a practice probably suggested by the benefit derived from their external application to wounds. Internally, as we have stated under the head of HÆMOPYSIS, q. v., they are of doubtful and suspicious efficacy, unless they are such as unite a sedative power. We mean not to include in this censure astringent applications in bleedings of the nose, for these are external remedies.

Saturnine remedies are the doubtful astringents we have alluded to: they are very certainly sedatives of the most powerful kind, and an exception to the tonic powers of metals in general. Every preparation of lead is, however, supposed to be deleterious, and the cause of the colica pictonum; but scarcely in any instance does lead produce this effect, except from long continuance. Dr. Reynolds' courage has been extolled in ordering a grain of acetated lead in a single dose. Five times that quantity may be given twice a day for some days, interposing only an oily laxative every other day. We have often employed it in hæmorrhages, sometimes with success; but it is certainly inferior in its sedative effects to nitre.

Preventing the return of the blood to the heart by means of ligatures on the extremities has been a mode of relieving hæmorrhages; but the plan is injudicious, and it will scarcely in any instance succeed, unless after a few minutes trial; for the course of the blood in the arteries is soon interrupted, and an increased impetus of the whole circulating system is the consequence.

Various are the objects of superstition and horror employed for the same purpose, and probably with success; for terror annihilates every function, checks the circulation, and will even produce the deliquium which is the constant cure of the complaint.

Among the causes of hæmorrhage, we have mentioned that want of energy in the arterial system which prevents the circulation being carried on to the extremities. Practitioners may often observe hæmorrhages, with some appearances of activity, in the debilitated and the indolent of spare habits, without any marks of plethora. Such patients can scarcely be reduced lower;

and we have found a fuller diet, exercise, a moderate quantity, or rather an additional quantity, of port wine, not only useful but necessary in such cases of hæmorrhage.

Passive hæmorrhages are those which are independent of fever, and in which the blood is poured out either by anastomosis or rupture of vessels. The former term is perhaps not sufficiently correct: it means a discharge of blood through the exhalants. Rupture of the vessels, however, is not uncommon in the last stage of debility, or in old age. All the appearances of catamenia in the advanced periods of life, are probably rather passive hæmorrhages than the proper menstrual discharge. Perhaps, in a strict view, all ruptures should be excluded from this class; but if no effort is perceivable, no increased impetus obvious, we are not authorized in supposing that any exists.

The causes of passive hæmorrhages are either extreme debility, or a dissolution of the blood. The serum is dissolved in the serosity by the means of neutral salts; and an alkali, or even common salt, carried in an unusual quantity into the circulating system, will apparently produce a dissolved state of the fluids. From Dr. Stark's experiments, it is probable that sugar, used in excess as an article of diet, will have a similar effect. Some poisons will, it is said, produce this disease. The hæmorrhoids of Lucan may be fabulous; but the effects are peculiarly striking.

“Sanguis erant lacrymæ: quæcunque foramina novit
Humor, ab his largus manat cruor: ora redundant,
Et patulæ nares: sudor rubet: omnia plenis
Membra fluunt venis: totum est pro vulnere corpus.”

Strange, however, as it may appear, we have seen even this picture realized, in a stout young farmer, without any known cause. We have seen it in a less degree in a delicate woman from excess of nourishment, taken for a supposed weakness. Each recovered: the first by the most active exhibition of the bark and mineral acids, the other by regulation of diet. In the former the muscular strength was apparently not impaired.

The cure of passive hæmorrhages chiefly depends on tonics; and of these, as we have said, the bark and the mineral acids are the most effectual; but even passive hæmorrhages are often relieved by refrigerants, particularly by nitre.

In external hæmorrhages the blood chiefly proceeds from the arteries; for even the bleeding from a large vein, if divided, ceases, from fainting coming on. When the wound or the size of the artery is considerable, a tourniquet above the wound is necessary; but in slight cases a compress of lint, or of lint mixed with the powder of vitriolated copper, confined with a proper bandage, is sufficient. The needle and ligature are sometimes necessary. See WOUNDS OF THE ARTERIES.

HÆMORRHA'GIA NA'SI, *epistaxis* of Cullen, in the class *pyrexia*, and order *hæmorrhagia*. He defines it pain or load of the head, flushing of the face, with a flow of blood from the nose, of which he names one idiopathic species, *hæmorrhagia plethorica*, and six symptomatic; four from internal, and two from external causes. Hippocrates means by epistaxis, repeated distillations of blood from the nose; and Fernelius observes, that “persons whose viscera and liver are weak

and scirrhus are subject to frequent hæmorrhages of the nose, as well as dropsical patients;” but, in general, it is the disease of the young and the plethoric.

The causes, in general, are the same as in other morbid hæmorrhages.

Epistaxis is often preceded by some degree of quickness in the pulse, flushing in the face, pulsation in the temporal arteries, heaviness in the head, dimness of sight, heat and itching in the nostrils; preceded, like other hæmorrhages, by a stricture of the skin, chilliness, lassitude, and often costiveness.

In many instances the loss of blood by the nose is salutary, as in fevers, vertigo, headach, epilepsy, dimness of sight. Those who in childhood often bleed at the nose when older become subject to hæmoptysis, rheumatism, and hæmorrhoids. When considerable headach has preceded, or the patient been subject to vertigo, or other diseases proceeding from too great an accumulation of blood in the vessels of the brain, bleeding at the nose should not be rashly checked. In fevers, when there is a load in the head, the same caution has been given; and it is, perhaps, the safest general rule: but we think even in the beginning of fevers we have found it lower the strength in too great a degree; and it should be apparently regulated rather than permitted to proceed till the patient faints. The nose is peculiarly adapted to deplete the arteries of the brain, as its vessels are numerous, their coats thin, and they are supplied with blood both from the external and internal carotids, which freely anastomose in this organ.

When it is to be checked, the remedies, mentioned under hæmorrhage, will be proper; but particularly nitre and the neutral laxatives. A cold wet napkin, or a sponge full of cold vinegar, with water, may be applied to the forehead and nose; and any thing very cold put down the back will occasion a shiver, during which the bleeding is checked. Dossils of lint, wetted with water, or oxymel, are often advantageously introduced into the nostrils.

When, notwithstanding every medicine and application, the blood continues to flow from the nose, the following method is often effectual. The hint of this method of stopping up the nostrils and passage to the throat is taken from Le Dran's Operations, case vi. in the Remarks, and easily cures the complaint. “Take a piece of strong sewing silk, wax it well, and to one end of it fasten a dossil of lint; then take a piece of catgut (about the size of the second string of a violin,) and introduce it up the bleeding nostril: when you perceive it in the mouth, take hold of its end with the forceps, and draw it out from thence, make a knot upon it, and fasten the end of the waxed silk to it; then withdraw the catgut back again by the nostril, take hold of the silk, and pull the dossil of lint into the posterior nostril; after which stuff the anterior nostril full of lint, and thus you certainly stop the bleeding. After a few days the lint may be taken away.” See Hoffman; and Van Swieten's Commentary on Boerhaave's Aphorisms; Cullen's First Lines, edit. 4. vol. ii. p. 256; Bell's Surgery, vol. iv. p. 70; London Medical Transactions, vol. iii. p. 217; White's Surgery, p. 263.

HÆMORRHA'GIA UTERI'NA. See MENORRHAGIA.

HÆMORRHA'GIA HEPATIS, vel INTESTINO'RUM. See MELAINA, and MORBUS NIGER.

HÆMORRHA'GIA RE'NUM, vel VESICÆ. See URINA.

HÆMORRHODA'LIS, (from hæmorrhoids, the piles). HÆMORRHODAL FEVER. It is of short duration, and considered as symptomatic. Vogel defines it an ephemera, attended with pain of the spine, piles, or at least painful varices, breaking out about the fourth day, which terminate the disease.

HÆMORRHODA'LE, or HÆMORRHODALIS HE'RBA, (from hæmorrhoids, the piles). See CHELIDONIUM MINUS.

HÆMORRHODA'LES ARTE'RIÆ, (from the same). HÆMORRHODAL ARTERIES. They are the external and internal.

HÆMORRHODA'LIS INTE'RNA ARTE'RIA (see MESENTERICÆ ARTERIÆ), soon divides into branches, one of which runs down behind the intestinum rectum, to which it is distributed into several ramifications, and communicates with the arteriæ hypogastricæ.

HÆMORRHODA'LIS EXTE'RNA ARTE'RIA. See PUDICA ARTERIA.

HÆMORRHODA'LIS EXTE'RNE VE'NÆ. The EXTERNAL HÆMORRHODAL VEINS. They spread about the intestinum rectum and anus; and proceed from the hypogastricæ venæ: they communicate with the hæmorrhoidales internæ.

HÆMORRHODA'LIS INTE'RNA VE'NA. *Mesaraica minor vena.* The INTERNAL HÆMORRHODAL VEIN; the lesser mesaraic vein. It is called hæmorrhoidal, from the tumours often found at its extremity next the anus, and is one of the three great branches of the vena portæ ventralis, though sometimes it springs from the splenicæ: it sends a branch to the duodenum from near its beginning; then it is divided into two branches, one of which ascends, the other descends; the descending branch runs down on the left portion of the colon on its lower incurvations, and on the intestinum rectum to the anus. The hæmorrhoidal veins have no valves.

HÆMORRHOI'DES, (from αἷμα, blood, and ῥέω, to flow). The HÆMORRHOIDS, or PILES. A discharge of blood from the hæmorrhoidal veins, called the *open* or *bleeding piles*: when instead of this hæmorrhage there are large tumours, generally painful at the lower part of the rectum, they are called the *blind piles*. The disease is placed by Dr. Cullen in the class *pyrexia*, and order *hæmorrhagia*; and he defines it a heaviness, or pain of the head, giddiness, pain of the loins and of the anus; livid painful tubercles about the anus, from whence blood generally issues, which sometimes also flows without the appearance of any tumours. He distinguishes four species:

1. HÆMORRHOIS TUMENS, when there are external swellings on the edge of the anus, called *mariscæ*, distinguished by the terms bloody and mucous.

2. HÆMORRHOIS PROCIDENS, when the piles are external, and caused by a bearing down of the anus.

3. HÆMORRHOIS FLUENS, when the piles are internal, without external tumour or bearing down of the anus.

4. HÆMORRHOIS CÆCA, when there are pains and tumour about the anus, without any discharge of blood. In some cases there is a discharge only of mucus; and the disease is then called *leucorrhœis*.

Dr. Cullen thinks the hæmorrhoids often depends upon a certain state of the whole body; but it is often a mere local complaint. He would, not, therefore,

refer a complaint of this sort to local diseases; because some piles, though in the beginning they may be merely local, if they should return often, as is usual, at length become habitual, and a general disease. Every species of the piles should be arranged therefore, in his opinion, amongst general diseases.

From dissections, this disease is supposed to be an ecchymosis in the cellular membrane of the lower part of the rectum, from the extremities of the neighbouring vessels: if this be true it accounts for the great loss of blood without loss of strength; for it is gradually emptied into the ecchymosis, and from thence only pours out in appearance so copiously.

There is seldom much discharge from the external hæmorrhoidal vessels, but they readily admit of painful varices. The internal hæmorrhoidal vessels not only discharge copiously, but, when this discharge is suppressed, disorders of the liver, spleen, pancreas, mesentery, and intestines, seem to be produced.

These general views of hæmorrhoids have, however, always appeared to us unsatisfactory. Though the lax texture of the hæmorrhoidal veins admits of congestion, and, when a part of the intestine is inverted, the sphincter necessarily checks the return of the venal blood; yet these circumstances by no means explain the phenomena of this intricate disease. We have frequently alluded to the opinions of the German physicians, at the head of whom is Stahl, that the discharge is salutary, to repel it dangerous, and to promote it the best method of relieving various diseases of the viscera and head. Dr. Cullen is willing to refer all these effects to the hæmorrhage having been long established and become habitual. A distinction, however, so obvious could not have readily escaped even a prejudiced observer; but we believe it to be a fact, that even repelling the painful varices, or checking the discharge before it has become habitual, sometimes produces inconvenience. It is not also easily explained why such inconsiderable tumours should form an obstruction capable of exciting the action of the whole arterial system, and pouring out blood from its branches. If it is a fact also, that diseases of the liver are relieved by these discharges, it would be singular that the external as well as the internal tumours should have equally such a salutary effect, since the internal hæmorrhoidal vein only contributes to form the vena portæ. In short, every view of this kind is attended with considerable difficulties, which can only be eluded by at once denying all connection of hæmorrhoids with the general system, except when it becomes an habitual discharge. But it appears rash and presumptuous to deny, at once, what has been established in the opinion of able and experienced practitioners; opinions not hastily taken up, and as quickly resigned, but apparently resting on facts, the result of the observation of many years, in different and distant countries.

It may then be asked, are the hæmorrhoids varices only portions of veins enlarged? They may be so in many instances; but round, *circumscribed*, tumours are not readily explained, when we consider that the hæmorrhoidal veins have no valves: the very acute pain attributed to inflammation is not readily explicable, when we consider the great laxity of the coats of the veins, and the very few vessels found on them. Add to this, that an hæmorrhoidal tumour, when punctured, seldom

bleeds; that leeches do not more quickly fill themselves in this part than any other of the body. It is highly probable then that these tumours are not varices, but small follicles inflamed, generally painful, and on the evacuation of a costive stool excruciatingly so. Such small bodies, suspected to be glands, certainly exist near the verge of the anus, and have been supposed to resemble the *carunculæ myrtiformes* at the entrance of the vagina.

If these are admitted to be the substance of the hæmorrhoidal tumours, many of the difficulties will be removed, and some consistency given to the various phenomena of the disease; but to elucidate this subject, we must enlarge a little, as we have proposed, on the progressive changes in the balance of the circulation. We had purposed to defer it to the article *MAN (HOMO)*, where we intended to collect all those circumstances relative to his structure and constitution, both mental and corporeal, which cannot with advantage be displayed in distinct articles; but the application of these considerations will be more obvious in this place.

The vital fluid is contained in corresponding vessels, styled arteries and veins; but the former only are active powers. In the veins the blood is propelled by the adventitious aid of other muscular organs, secured in each step by valves. It is evident, therefore, that for the necessary support of the body, the action must bear some proportion to the resistance; for were either too great, the arteries would be emptied or infarcted. On inquiry, it appears that the proportion of the action to the resistance differs in different periods of our existence. Sir Clifton Wintringham showed, by experiment, that the density of the coats of the veins was greater in proportion to that of the coats of the arteries in young persons than in old. This proportion is gradually changing; and, after the acme of life, they are more nearly equal, or the resistance of the veins is little in proportion to the action of the arteries. If we look at the progressive growth of the body, we shall find this very wise distribution answers some important purposes; for the arteries, thus kept full, contribute to the evolution of the organs in succession; a change probably effected by expanding the nervous fibrils, which we have styled the *moule interieure*; and the same resistance throws the fluids into the exhalants, by which the nutritious particles are applied. This arrangement is no longer useful than during the increase of the body. The proportional action and resistance are, for a time, stationary; but at last the veins yield, and venous plethora is conspicuous. This is the period for apoplexies, for humoral asthmas, for infarcted viscera, and, to come nearer our object, for the bleeding piles.

In this succession we have already shown that the enlargement of the head first takes place, and its vessels are consequently filled. We trust it has not escaped our readers that we have anxiously pointed out the magnitude, the extent, and the dilatate structure of the venous system of the cerebrum, to show that nature carefully designs to keep the arteries full. Her object in this is from the present purpose; but though the resistance of the veins is considerable, a rupture of arteries, so carefully secured by a bony resisting covering, is prevented, and the anastomosing branches of both carotids yield to any increased impetus very easily in the nose. Hæmorrhages, from that organ, prevent the active hæmorrhagia cerebri; an appellation given by Hoffman

to apoplexies in young persons. Where the resistance in early age is considerable, it probably disappears more quickly; and from fifteen to thirty-five this danger from distended arteries is chiefly perceptible in the lungs. This point we have fully considered in the article HÆMORRHOÏSIS, q. v. It next appears in the epigastric, and successively in the hypogastric, region.

If in early age we perceive active hæmorrhages in the brain, in the more advanced periods we perceive similar effects from venous plethora. We then find those apoplexies and palsies from a languid circulation, in other words, from weakened resistance of the venous system. In the lungs we find, from the same cause, humoral asthma and hydrothorax; in the epigastric region, infarcted liver, and the morbus niger; in the hypogastric, hæmorrhoids. If we judge right, hæmorrhoids are of two kinds. It is a disease of youth, as well as of maturer age; and, in the former, is often acutely painful, without evacuations; in the latter, less commonly painful, but usually attended with bloody discharges. In each it seems a salutary determination from parts otherwise overcharged; and this we think is proved by many facts. In the very painful hæmorrhoids of young persons, saturnine and cold applications, which relieve pain, often induce sickness and faintness. In speaking of fistula, we have shown that checking the discharge is often injurious, and that consumptive symptoms frequently follow the operation and the healing of the wound. We will admit that such consumptions are connected with the state of the liver; but so far as we have seen, and the cases are not few, the age is not that of biliary congestions, but of accumulations in the lungs, viz. the consumptive period, from fifteen to thirty-five, generally from eighteen to thirty. It appears then highly probable that congestions on the thoracic viscera are relieved by others on these parts, and we thus see the connection of hæmorrhoids with the general health, independent of any venous connection with the liver. In these cases, the parts inflamed are carunculæ already mentioned, and the inflammation is active. Yet in the hæmorrhoids of advanced life, such congestions evidently take place. The disease is the venous, and the tumours, in the greater number of instances, varices: they bleed, and the patient is relieved. Congestion and inconvenience follow, to be again obviated by a recurrence of the hæmorrhage.

Those who are of a lax habit, disposed to eat heartily, and drink freely; who indulge in ease, and are habitually costive; are the most subject to this disorder.

Hæmorrhoids are, however, often local diseases: when the uterus presses on the neighbouring trunks of the veins, the hæmorrhoidal vessels swell, and often discharge blood. When resinous purgatives, which are slowly dissolved, and act only on the rectum, are exhibited, the piles follow; and this effect is particularly produced by aloës, sometimes by rhubarb. These are, in general, true varices; and the tumours are livid, soft, and bleed freely on being punctured; but the other tubercles in the anus, styled *piles*, are hard, and exquisitely painful.

The eruption of the hæmorrhage in the open piles is often preceded by spasmodic strictures, flatulencies, pain about the os sacrum, and various other symptoms, which disorder the whole frame. In the beginning of excessive discharges the blood is black and grumous,

afterwards redder, and at last it is mucous; at length the strength is impaired, the pulse is languid and trembling, a cachexy, a fatal hectic, or dropsy, comes on.

The piles are always readily distinguished; and attention is only required to prevent their being confounded with the colic, dysentery, or with syphilitic tumours about the anus.

When attended with an infarcted liver or spleen, a fatal hectic is the consequence: when the discharge is excessive, a dropsy. On the contrary, moderate discharges from the hæmorrhoidal veins are supposed to relieve a constitution oppressed by the gout, asthma, sciatica, diseases of the kidneys or bladder, hypochondriasis, hysteria, or mania. Those discharges only are deemed morbid by which the patient is enfeebled, and the constitution injured.

The general indications are, 1. To take off the increased impetus to the seat of the disease by bleeding and small doses of ipecacuanha. 2. To induce an astringent on the relaxed vessels; and for this purpose alum, the oak bark, or galls, may be employed. 3. To avoid all irritation, by regulating the stools, avoiding violent exercise and highly seasoned meats. An incautious use of improper diet will render the best medicines ineffectual in this disease. In general it should be light, cooling, and laxative. If, however, the distinctions we have endeavoured to establish be well founded, the hæmorrhoids of young persons should be treated as active inflammation, or a deposition of morbid matter, and the general regimen of HECTICUS, q. v. with a little more active depletion, may be employed.

Bleeding at proper intervals, where there is a sanguine plethora, will in some measure prevent the returns, or at least moderate their violence. Topical bleeding by leeches or punctures are also useful, though care must be taken that the leeches do not escape into the rectum. If that accident should happen, injections of a solution of common salt are the proper remedy; but the animal is soon gorged, and may then be destroyed.

When the disorder assumes a chronic form in the more advanced periods of life, and the piles do not bleed, they are attended with considerable pain; in which case dossils of lint, dipped in warm olive oil, may be applied; or olive oil, with an equal portion of brandy, or of tincture of opium, may be spread on soft rags, and retained by the T bandage. Saturnine applications relieve pain; but we have often found them produce sickness and faintness. Emollient fomentations and poultices, when the pain is excessive and inflammation violent, are useful. In this case also Mr. Ware recommends cutting out the principal pile, which is usually larger than the surrounding ones, with a pair of crooked scissors. This relieves the pain and inflammation; and the hæmorrhage, he says, is trifling. It could not be then an inflamed varix. If the piles are troublesome by their bulk, they may be dressed with a mixture of simple lime water, adding a small quantity of camphorated spirit of wine and a little of the cerussa acetata. See GALLE.

The bowels must be kept lax; and for this end the electarium e cassia is preferable to the electarium e senna comp. Sulphur, and the oleum ricini, are also useful laxatives. The former is supposed to have a specific effect in this disease, though later practitioners consider it only as a mild laxative. The long time during which

it remains in the intestines, previous to its operation, seems to show that it acts exclusively on the rectum, and supports in some measure the idea of a specific action. The walnut is supposed to have a similar effect, and the preserved walnut is said to be a very useful laxative in this complaint. A mixture of soap and wax we have found highly useful. When the intestine protrudes after a stool, the patient should be placed in bed, the protruded gut supported, and in this case the sphincter relaxing the intestine is restored.

If the case requires the assistance of a surgeon to check the hæmorrhage, a cooling purge may be administered, and, five or six hours before any operation, a clyster injected. The patient must then be laid in the proper position, and the operator may tie up the bleeding veins with a needle and thread; taking hold of any tubercles with the forceps, he may tie or cut them off. If the hæmorrhage continues, lint, with proper compresses, and the T bandage, should be applied. If the veins are high in the rectum, it must be distended with a convenient instrument until the operator can reach them. If the blind piles encompass the anus so as to prevent the discharges by stool, and prove otherwise troublesome, the largest may be removed by a ligature; the application of warm spirit of wine, or other repellants, will not disperse it. If the distended vein is high and inflamed, it may be opened with a lancet. When from long continued piles a fistula is apprehended, *Ward's paste* is sometimes useful. It consists of a pound of ekecampane root, with half as much black pepper, and a pound and half of fennel seeds, made into a paste with honey. When the piles are apparently continued from relaxation, two drachms of the tincture of muriated iron, with about a drachm and a half of opium, and four ounces of barley water, may be injected as a clyster twice a day.

See Hoffman; Heister's Institutes; Lobb on Painful Distempers; Le Dran's Operations; Cullen's First Lines, vol. ii. p. 424. edit. 4; Bell's Surgery, vol. i. p. 249; White's Surgery, p. 383.

HÆMORRHOÏDES EXCEDE'NTES; *immódicæ; polyhódæ*, belong to the *hæ'morrhôis tímens*; the *hæ'morrhoides decolorátæ*; the *hæ'morrhoides álba* and *múcidæ*, differ only in the appearance of the discharge, which is mucous, not bloody. See HÆMORRHOIDES.

HÆMORRHOIS AB EXA'NIA. See HÆMORRHOIS PROCIDENS.

HÆMORRHOU, (from *áima, sanguis*, and *ῥεω, fluo*). The name of a poisonous serpent (see P. Ægina, lib. v. cap. 15,) or those large veins, which, when opened, discharge the blood copiously. Hippocrates.

HÆMOSTA'SIA, (from *áima, blood*, and *ιστημι, to stand*). A general stagnation of blood from a plethora.

HÆMOSTA'TICA, (from *áima, blood*, and *σταω, to stop*). Medicines which stop hæmorrhages.

HÆRMIA. An Indian fruit, said to resemble pepper (see Lemery des Drogues;) not noticed by botanists.

HAGIOSPE'RMON, (*άγιος, holy*, and *σπερμα, semen*; from its reputed virtues). See SANTONICUM.

HAGIO'XYLON, (*άγιος, holy*, and *ξύλον, wood*; from its virtues). See GUAIACUM LIGNUM.

HAIR. See CAPILLUS and PILUS.

HAIR WORM. See GORDIUS.

HAIR LIP. See LABIA LEPORINA.

HALCHE'MIA, (from *άλς, salt*, and *χειω, to pour out*). The art of fusing salt.

HA'LCYON, (from *άλς, the sea*, and *κυω, to bring forth*; a bird which lays its eggs in the sea). See ALCEDO.

HALCYO'NIUM, (from *άλκυων, the king's fisher*, which is supposed to build its nest with it). The spume or froth of the sea.

HA'LEC, *harengus*, the HERRING. Pickled herrings are applied to the soles of the feet as sinapisms. Fresh herrings are supposed to be alkalescent, and are useful when an acid prevails in the stomach. It is an oily food, and often disagrees. See ALIMENT.

HALICA'CABUM, (from *άλς, the sea*, and *κακαζος, nightshade*; because it grows on the banks of the sea). See ALKEKENGİ.

HA'LICES. Yawning after sleep.

HA'LIMUS, (*άλς, the sea*; from its brackish taste); *portulaca maritima*; *atriplex maritima angustissimo folio*; *atriplex portulacoides* Lin. Sp. Pl. 1493; COMMON SEA PURSLANE, and TREE SEA PURSLANE, is found in marshes; flowers in July and August. Dioscorides tells us that the leaves are eaten as food; and Ætius, that the buds are used as pickles. The plant is warm, and when pickled is supposed to assist the appetite and digestion.

HALINI'TRON, (from *άλς, and νιτρον*). NITRE; more probably ROCK SALT.

HALLUCINATIO'NES, (from *hallucino, to err*). See DYSÆSTHESIÆ.

HA'LMYRAX, (from *άλς, salt*). The nitre produced in the valleys of Media.

HALMYRO'DES, (from *άλμυρος, salted*). An epithet of some fevers, in which, according to Galen, the external parts communicate to the touch such an itching sensation as is perceived from handling salt substances. When applied to the skin, it signifies a roughness as if salted. It is also an epithet for many excretions that are salt and acrimonious.

HA'LO, (from *αλωω, an area, or circle*. See AREOLA.

HA'MBARA, and HA'MBRUS. See SUCCINUM.

HAMPSTEAD WATERS. See AQUÆ MINERALES.

HA'MULUS. An anatomical term applied to any process resembling a hook, as that in the pterygoid bone.

HA'MUS. A hooked instrument for extracting a dead child from the uterus.

HA'NDALA, (from *handal, Arab.*). See COLOCYNTHIS.

HAOU'VAY. See AHOVAI THEVETECLUSII.

HA'PSIS, (from *άπιω, to connect*). The sense of FEELING. It also signifies the connection of bandages; and *άψις φρενων*, in Hippocrates, signifies madness, delirium, or loss of reason.

HAPSICO'RIA, (from *άψιχορος, fastidious*). LOATHING; as the "conviva satur."

HARE'NGUS. See HALEC.

HA'RMALA, (from *harmal, Arab.*) *ruta sylvestris*. ASSYRIAN WILD RUE. *Peganum harmala* Lin. Sp. Pl. 638. Its leaves are longer and narrower than the common rue, with but little scent: it grows in Spain and in the east, resembles the common rue in its qualities; but is rarely used. Raii Historia. See RUTA.

HARMA'TTAN. A prevailing wind on the coast of Africa, between Cape Verd and Cape Lopez, during the months of December, January, and February. (See Philosophical Transactions, vol. lxxi). It demands a place in this work, on account of its singular dryness, and its effects on the human body. The wind passes over the burning deserts of Africa, and is so dry that it rapidly absorbs moisture, and in a very short time the leaves and all the more tender plants are parched like hay. The skin becomes dry and chapped, the nose and lips sore, the fauces arid, and the sweat from the parts defended from its influence is highly acrid. Yet it is generally accounted healthy; though Dr. Lind gives it a different character, who calls it a fatal wind, perhaps confounding it with a simoon.

HARMONIA, (from *αρω*, to fit together). In anatomy it is a species of articulation, where two thin bones meet and lie over each other.

HARMOS; (from the same). See GINGIVÆ.

HARPA'STRUM. A species of exercise with a ball.

HAR'PAX, and **HAR'PAGA**, (from *αππαζω*, to seize). See SUCCINUM. Also a mixture of quicklime and sulphur.

HARROWGATE WATER, a salt, purging, sulphureous water; the strongest in Great Britain, of the heat of 92°, but it does not lose its sulphureous smell even in a boiling heat. It is perfectly clear; and in taste and smell resembles rotten eggs and sea water combined. It was doubted whether these waters contained any sulphur: but it is now ascertained, and the sulphur is in the state of hepar sulphuris. A gallon of this water contains one pennyweight twelve grains and a quarter of carbonated lime; four pennyweights twenty-three grains of muriated magnesia; and an ounce seven pennyweights and twelve grains of sea salt. It contains also four ounce measures of acidulous gas, and thirty-five of fetid inflammable gas, such as is separated from hepar sulphuris by vitriolic acid. In small quantities these waters prove diuretic; in large, purgative. They are extremely useful in cutaneous and scrofulous disorders; in piles; as anthelmintics, destroying, if employed so as to purge, lumbrici and ascarides; and in debility of the digestive powers. In dropsical, scorbutic, and gouty cases, they are highly recommended. Externally they are considered as discutient and attenuating; and, used as a warm bath, remove stiffness and pains of the joints from strains, hard or scrofulous tumours, and greatly improve the state of old ulcers. When first drunk the water occasions slight giddiness and headach, which are carried off by its laxative effects. It should be used cold and fresh from the spring; and it has been employed externally in form of washes, fomentations, and baths, particularly in cutaneous diseases. See *Monro on Mineral Waters*, and *Garnett on Harrowgate Water*. At Harrowgate is also,

1st. The *sweet spa*, which strikes a light purple with galls, and from a gallon affords, on evaporation, a scruple of solid matter at one time, and eight grains at another: of these sediments, above one half was earth, the rest a vitriolated magnesia.

2. *Tuwphet*, of which a gallon yielded at one time thirteen grains, at another nineteen, of which three fifths were calcareous earth mixed with ochre, the rest

vitriolated magnesia. It was discovered in 1638, and formerly the only one used internally, chiefly in nephritic cases.

3. *Alum well*, which, from its roughness, was supposed to contain alum; but seems to be impregnated with vitriolated or carbonated iron. Dr. Short properly considers these as chalybeate springs.

HARTFELL WATER, issues from the Hartfell mountain in the county of Annandale, Scotland. It is quite pure and pellucid; has a chalybeate and so strong a styptic taste, that it was suspected to contain alum; but, by being exposed to the open air, it becomes weaker, and is observed to be stronger in wet than in dry weather, so that it is more probably a chalybeate; and on evaporation afforded 0.9 of vitriolated iron. Some portion of iron is also suspended by carbonic acid.

This water is recommended in cases where chalybeates are useful; in menorrhagia, fluor albus, gleet, old dysenteries, in diseases arising from relaxation, and in some circumstances of hectic. It sometimes at first produces giddiness, and consequently small quantities should be first used. A pint is a sufficient dose in one day. See *Monro on Mineral Waters*.

HASTA RE'GIA. See ASPHODELUS LUTEUS.

HASTA'TUS, (from *hasta*, a spear). Botanically it is applied to a leaf which resembles the head of a halbert.

HASTE'LLÆ, (a diminutive of *hasta*, a spear). Splints used in fractures.

HAUD, (Arabic). Wood; the Arabian name of *agallochum*, by way of eminence, the wood. It is distinguished by different appellatives, as *haud alcumeri*; *haud hend*, and *haud heud*.

HAU'STUS, (from *haurio*, to swallow). A DRAUGHT. Draughts are only single doses of medicines in a liquid form; vomits, purges, opiates, and such as require great nicety in the dose, are given in draughts. This form of medicines is sometimes employed merely as a vehicle for pills or powders, and is then usually pleasant, and very slightly, if at all medicinal. Highly nauseous medicines, heavy and insoluble powders, or substances which very quickly ferment, are improper to be given in draughts.

HA'VEA GUIANE'NSIS. See CAOUTCHOUC.

HAVE'LIA. See HURA.

HAVE'RI GLA'NDULÆ. HAVERS' GLANDS. They are the sinovial glands, and called from *Havers*, who first discovered them.

HEAT VITAL. See CALIDUM INNATUM.

HAZEL NUT. See AVELLANA.

HEALTH. See HYGIENE.

HEBDOMADA'RIA, (from *ἑβδομας*, a week,) one of the febris erraticæ.

HE'BE, (from *ἠβαιω*, to grow ripe). The hairs which grow upon the pubes; the part on which they grow; or the age when they appear.

HEBI'SCOS. See ALTHÆA.

HE'CTICA, vel **E'THICA**, (from *ἔξις*, habit,) the SYMPTOMATIC FEVER; IRREGULAR INTERMITTENT FEVER; FEVER OF SUPPURATION; and SLOW FEVER. Hippocrates describes this fever under the name of *phthisis*: But Celsus is the first who speaks of it under that of *hectic*, and he directs the cure; what were afterwards called *slow hectic fevers*, were, among

the first physicians, called *tabid*, or *long continued fevers*, or *marasmi*. At present by this term is meant slow, but long continued, fevers, which induce consumption, and impair the strength. Dr. Cullen considers hectic always as symptomatic. He describes it a fever returning every day, with meridian and evening accessions; with remissions, but seldom a total freedom from fever; generally attended with night sweats, the urine depositing a lateritious branny sediment. He adds, that as all nosologists have admitted the hectic amongst the number of fevers, he has given its character; but that he never had observed a fever of this sort except when symptomatic, therefore he could not admit it to be enumerated amongst idiopathic fevers. In many examples given by Sauvages this fever is certainly symptomatic: but to prove a negative is very difficult; and if no internal disease to which it can be traced as a symptom can be discovered, we must allow it to be occasionally idiopathic. It has been called *febris remittens chronica non critica*, as it has no crisis, and is of long continuance.

On dissecting patients whose death was the consequence of a hectic, abscesses in some of the viscera, scirrhus or steatomatous tumours, are very often found.

Intemperate drinkers, and those who indulge in excess of any kind, are very subject to it; and disordered glands, abscesses, or ulcers in the internal parts, generally induce it: but these abscesses sometimes exist without a hectic, and the liver, sometimes even the lungs are found ulcerated when no fever had been observed.

The matter producing hectic may be formed in any part of the body, though perhaps in the lungs, and the glands of the mesentery, its source may be most commonly traced. A scirrhus gland, in any part, almost constantly produces this fever; particularly a scirrhus liver from hard drinking, or long residence in a warm climate. External accidents will sometimes occasion irregular exacerbations. Even a wound with a fine pointed instrument, according to Dr. Heberden, has produced this effect. Dislocations of the joint often produce shivering and disorders of the stomach; and the introduction of a catheter is attended also with shivering, often followed by the hot fit. A salivation is sometimes the cause.

The hectic arising from external inflammations and suppurations is longer in its attack and slower in its progress, in proportion to the magnitude and importance of the part. Thus in the joints, the usual seats of the disease, suppurations of the ankle, wrist, elbow, and even the shoulder, have often continued long before the constitution has suffered. On the contrary, when the knee, the hip joint, or the loins, are the seat of the disease, hectic soon comes on. During the continuance of wounds it sometimes comes on, and is then attended with every mark of debility.

Dr. Reid, in his *Essay on the Nature and Cure of the Phthisis*, denies that the absorption of the pus is the cause of the fever which attends that disease; but attributes it to the very large quantity of perspirable matter usually discharged from the surface of the lungs, which is retained when this organ is injured, and only evacuated in the hectic sweats. As the lungs, by the increase of the disease, are less capable of exhaling the usual quantity of gas, exacerbations and the morning

sweats are proportionally increased, or the matter falling on the intestines, produces a diarrhoea. From being usually costive, the patient hath frequent motions, and, in proportion to their number, the sweating and expectoration are diminished. The quickness of the pulse between the paroxysms he attributes to the progressive inflammation of the different tubercles. On this opinion we may make some remarks in a future article.

Many other authors have contended that hectics are not owing to the absorption of purulent matter; and their arguments are entitled to considerable attention. Mr. Hunter has urged many facts in opposition to the generally received opinion; and it must be admitted, that should absorption be generally the cause, the lymphatics act very irregularly, at different times, and in different situations. We know, indeed, that fluids exposed to the mouths of the absorbents are sometimes not taken up, and soon afterwards, without any apparent reason, rapidly disappear. Though this caprice may account for some of his observations, yet the facts before stated, where hectic fever follows only suppuration of some of the larger and more important joints, cannot be accounted for in the same way. In some external abscesses also, we find that the hectic begins to appear only when they are opened; and though the suppuration of scrofulous tumours is attended with fever, venereal ones produce no general effect on the constitution. Mr. Hunter concludes that "the hectic is owing to the parts being stimulated to produce an effect beyond their powers, and that this stimulus is sooner or later in taking place, in different cases."

The connection between hectic and suppuration is, however, apparently so close, that we are unwilling to give up our former opinion; and we can perceive, we think, some clue to conduct us through the labyrinth of discordant facts. We would conclude, therefore, that *hectic is owing to suppuration of any considerable magnitude arising from constitutional disease*; and these constitutional diseases are such as are usually attended with increased irritability, or a broken constitution.

The appearance of hectic resembles that of an irregular intermittent. The pulse rarely becomes natural; but remains quick and weak: the chillness is often violent and long continued; not regularly succeeded either by a dry heat or sweat, though one of these generally follows; and the hot fit sometimes approaches without being preceded by a sensible chillness. The sweat seems to exhaust instead of relieving the patient, and when at an end, the fever will sometimes continue, or in the middle of the fever the chillness will return; a certain sign, according to Dr. Heberden, of the presence of this fever and its pathognomonic symptom. The return of the fits is equally irregular. Sometimes they recur, for a considerable time, at regular periods, and again lose this strictly intermittent form. In the fit, the urine is various, and nothing can be ascertained from its appearances. When an external ulcer is the cause, pains, apparently rheumatic, occur, though in a part very remote from the ulcer; and a sudden swelling of some part of the body is occasionally observed, which soon subsides. Its approach is usually gradual, the skin is dry, the tongue hard and parched, the cheeks flushed, the sleep not refreshing. On the approach of the fit, according to Hippocrates, the whole breast is pained, the breath resembles a whistling through a reed, a cough often

attends, a quantity of thin saline saliva is discharged, and, in the progress of the disease, the whole body is emaciated, except the legs, which become tumid. A pathognomonic sign, according to Galen, is an increase of fever after eating and drinking.

The hectic fever should be distinguished from the intermittent, the common inflammation, and the slow or nervous fevers. The intermittent is more regular in its form, and in its attacks; and the slow nervous fevers have not such marked exacerbations or remissions. The fever of inflammation is of the continued kind. Dr. Reid distinguishes the hectic of a pulmonary consumption from the fever, in consequence of abscesses or ulcers in other parts, as in the liver, or under the psoas muscle, by the absence, in the latter, of remissions and morning sweats: on the contrary, it is more continued, less violent, and the skin is usually dry. But this distinction is apparently unfounded.

If the pulse runs on to above 100, or from this number to 120, in a minute, the danger is considerable; though sometimes the pulse will be little affected, while a variety of other fatal symptoms attends. In lying-in women it is generally fatal; and the fatal signs are, a continually weak, quick pulse, an entire loss of appetite and strength, an Hippocratic countenance, a little red or oily urine, a diarrhoea, immoderate sweats, with swelling of the feet and legs.

In most cases the principal intention is to relieve the symptoms, to moderate the heat, prevent costiveness, or its opposite, check the night sweats, and at the same time assist the general health, by exercise, air, and a proper diet; in other words, to support the strength, without adding any stimulus.

The remitting tendency of the disease has suggested the use of the bark; but this remedy is usually injurious, as it produces stricture on the skin, increases the heat, and, in pulmonary cases, the dyspnoea. In these cases neither antimonials, camphor, nor squills, will obviate the injurious tendency of this remedy. Though they appear to lessen the bad effects, they do not render the medicine beneficial. The eleutheria is more useful, but seldom produces any striking advantage. The purer bitters often succeed: of these we may mention the gentian, the camomile flowers, and perhaps the uva ursi. Of the angustura bark we cannot speak so decisively as we may be able to do under phthisis, as it is at present the subject of our trials. With these the neutral salts may often be combined with salutary effects, and together they will produce that gentle looseness which very essentially diminishes hectic heats.

The cooling medicines are in general preferable, and these united with mild doses of antimonials are often highly advantageous. The myrrh seems to act as a sedative in lessening febrile heat; but we find little advantage in combining it with chalybeates, as in Dr. Griffith's mixture; nor do we think the Pyrmont water so useful as the Seltzer. The steel may succeed in debilitated constitutions where the liver appears to be much affected, and in the Cheltenham waters it is said to be salutary, and to prevent the debilitating effects of the neutral salts.

The balsams have been highly commended in these diseases; and with nitre, or the citrat of potash, we have thought the Peruvian balsam, in slight doses, an

useful corroborant: in larger doses it is too stimulating. The cicuta with mercury has been given as a deobstruent; and in the hectics from scirrhus livers, the production of the fevers of hot climates, it is said, with success. In some cases of hectic, from suppressed hæmorrhoids, Bath waters have been advised. Should hectics arise from repelled gout, they may be also applicable; but in general these and all other stimulating remedies are injurious. When this disease is connected with wounds, asafoetida, with opium, has been useful.

In conformity to the most successful plan of treatment the diet should be mild and gently nutritious. Broths, milk, and vegetables, are the most useful; though a slight proportion of animal food, at an early dinner, may be not only allowed but recommended. A dry free air, with gentle exercise, particularly on horseback, is highly useful. An airy room, with light covering at night, is equally proper.

We have not mentioned bleeding; because, though sometimes employed in pulmonary hectics, it is not generally useful in this disease. We shall particularly mention it under PHTHISIS, q. v.

See Hippocrates de Internis Affectionibus; Aretæus de Curatione Acutorum, lib. ii.; Fernelius; Hoffman; Heberden's Observations in the London Medical Transactions, vol. ii. p. 1—17; Fordyce's Enquiry into the Causes, &c. of Putrid Fevers; Cullen's First Lines, vol. ii. 221, &c.

HE'DERA, (from *hæreo*, to stick; from its attachment to trees and old walls). IVY.

HE'DERA ARBOREA. COMMON OF TREE IVY; *corymbus*; *hedera helix* Lin. Sp. Pl. 292; is an evergreen plant, climbing and spreading on old walls and trees; the leaves are angular; the flowers appear in autumn, and are followed in winter by clusters of black berries.

The leaves are nauseous to the taste; but commended by the Germans in the atrophy of children, in rickets, ozæna, and epiphora. By the common people they are used to keep issues open, and applied to sores that have a thin discharge. In the plague the powder of the leaves, with vinegar, has been commended. The dose is from ℥i. to ℥i. Quercetanus made an extract from the berries; *extractum hurgans*. From the stalks of the plant a resinous juice exudes in warm countries, called *gummi hederæ*, of a reddish brown colour without, and of a bright brown yellow within, of a vitreous splendour, but not pellucid: when rubbed it emits a light agreeable smell, and is of a resinous, slightly aromatic, and subastringent taste; chiefly used like other resins in plasters.

HE'DERA TERRESTRIS; *chamæcissus*; *chamælema*; *calamintha humilior*; *corona terræ*; *bacchica chamæclema*; GROUND IVY; ALE-HOOF; SUN-HOOF; JACK IN THE HEDGE; GILL GO-BY-THE GROUND; *glecoma hederacea* Lin. Sp. Pl. 807; is a low, hairy, creeping plant, with square stalks; roundish or kidney-shaped leaves, set in pairs at the joints; the flowers are bluish and labiated; the upper lip is cloven and turned backwards. It is common in hedges and shady places; flowers in April, and the succeeding warm months; is generally greenish all the winter.

This herb has a quick, bitterish, warm taste; an aromatic, but not very agreeable, smell, in a great measure dissipated by drying. It is supposed to be useful in dis-

orders of the breast, and as an attenuant. In obstinate coughs it is a favourite medicine with the poor, given in the form of tea, sweetened with honey; and Dr. Pitcairn speaks highly of it in consumptions. Dr. Cullen found no evidence of its diuretic or pectoral effects, and thinks it very improbable that it should be useful in phthisis. Alc is rendered very fine by an infusion of ground ivy, and called *gill-ale*. It yields its virtue most perfectly to water by infusion, and, on inspissating the filtered liquor, only the unpleasant smell is lost. See Lewis's *Materia Medica*.

HE'DERÆ GU'MMI. See HEDERA ARBOREA.

HEDER'ACEÆ, the forty-sixth order of Linnæus. Fragments of a natural method.

HEDERU'LA AQUA'TICA, (a dim. of *hedera*). See LENTICULA AQUATICA TRISULCA.

HE'DRA, from ἕδραι, *to sit*). Synonymous with APUS, q. v.; sometimes with excrement; the basis of an abscess; or the part on which the matter rests: according to Hippocrates, a species of fracture.

HE'DRICOS, (from ἕδρα, *anus*). An epithet for remedies appropriated to the anus.

HEDY'CROON, (from ἡδύς, *sweet*), a mixture of a number of aromatic ingredients, formed into troches, said first to be invented and described by Andromachus. Their composition is in some of the later dispensatories.

HEDYO'SMOS, (from ἡδύς, *sweet*, and οσμή, *smell*). See MENTHA.

HEDY'PNOIS, (from ἡδύς, *sweet*, and πνεῦμα, *to breathe*). See DENS LEONIS.

HEDY'SARUM GLYCYRRHIZA'TUM. See GLAUX VULGARIS LEGUMINOSA.

HEDY'SMATA, (from ἡδύς, *sweet*). See STYMATATA.

HEL'CONIA, (from ἕλκος, *an ulcer*). An ulcer of the cornea.

HELCY'DRION, (from ἕλκος, *an ulcer*, and ὕδωρ, *water*). A small ulcerous pustule.

HELCY'STER, (from ἕλκω, *to draw*). A hook for extracting the fetus.

HELE'NIUM, (from *Helene*, where it grew. See ENULA.

HELE'NIUM I'NDICUM. See BATTATAS CANAD.

HELEOSELI'NUM, (from ἕλος, *a fen*, and σελινον, *furslane*; from growing in marshy places). See APIUM.

HELIA'NTHEMUM, (from ἥλιος, *the sun*, and ἄνθος, *a flower*; because its flower turns to the sun). See CHAMÆCISTUS, BATTATAS CANADENSIS.

HELICA'LIS MA'JOR, HELICA'LIS MI'NOR, (from ἑλίζ, *the outer border of the ear*). See AURICULA.

HELICHRY'SUM, and HELIOCHRY'SON, (from ἥλιος, *the sun*, and χρυσός, *gold*). GOLDYLOCKS. See ELICHRYSUM, also GNAPHALIUM MONTANUM.

HELIDÆ'I PULVIS. See EUPHRASIA.

HELIOSCO'PIOS, (from ἥλιος, *the sun* and σκοπεῖν, *to behold*; because it turns to the sun). See TITHYMALUS.

HELIOTRO'PIUM, (from ἥλιος, and τρεπῶ, *to turn to*). TURNSOLE, or HELIOTROPE. The flowers are funnel shaped; their brims cut into ten unequal segments; collected into a long reflexed spike, resembling a scorpion's tail; each flower followed by four naked gibbose seeds. *Heliotropium Eurofiæum* Lin. Sp. Pl. 187.

HELIOTRO'PIUM MA'JUS. The GREAT TURNSOLE. Its leaves are bitter; the petals are changed to a deep blue by alkalis, and to a red by acids, and are consequently the chemist's test for the presence of each. The juice of this plant destroys warts; and a decoction of it is said to be an active purgative.

HELIOTRO'PIUM TRICO'CCUM; *ricinoides*; FRENCH, or COLOURING TURNSOLE; *croton tinctorium* Lin. Sp. Pl. 1425. This species grows plentifully in France; the leaves are of a pale green; the flowers yellow: when the berries are expressed, linen rags are dipped in the juice, and exposed to the vapour of urine, which gives them a red colour. The colour of this species of turnsole is extremely susceptible of alteration by acids. See Raii *Historia Plantarum*.

HELIOTRO'PIUM I'NDICUM. See BATTATAS CANADENSIS.

HE'ELITIS, (from ἥλος, *a nail*; because it was used to be beaten from nails and pins). See ÆRIS SQUAMÆ.

HE'LIX, (from εἰλεω, *to turn*). A SPIRAL LINE. See AURICULA.

HELLEBORA'STER, HELLEBORA'STRUM, (from ἑλλεβορας, *hellebore*). BEAR'S FOOT. See HELLEBORUS FÆTIDUS.

HELLEBORI'ZE. Hippocrates and his successors introduced hellebore into the rectum, both for vomiting and purging, altering the strength according to circumstances; and the effects were called *helleborizing*.

HELLEBOROI'DES, (from ἑλλεβορας, and εἶδος, *likeness*), *aconitum hyemale*; *aconitum luteum minus*; *aconitum unifolium luteum bulbosum*; *helleborus hyemalis* Lin. Sp. Pl. 783. The leaves resemble those of the aconitum; but in general it agrees both in appearance and virtues with the black hellebore.

HELLEBORO-RANU'NCULUS. The leaves are single, and roundly turned like those of the ranunculus, and of the same colour with the flower, which is rosaceous. It is said to be caustic, and is probably the helleborus hyemalis, mentioned in the preceding article.

HELLE'BORUS, or ELLE'BORUS, (παρα το τη βορα ελειν, because it kills if eaten,) *nicon*; the name of several rosaceous flowered plants, and of female sanicle. See IMPERATORIA NIGRA.

HELLE'BORUS FÆTIDUS. *Helleboraster*; *helleborastrum*; *helleborus niger fatidus*; *elleborine*; *veratrum nigrum*; GREAT BASTARD and FETID BLACK HELLEBORE; SETTLE, or SETTERWORT; BEAR'S FOOT; *helleborus fatidus* Lin. Sp. Pl. 784. This root is small, but surrounded by numerous dark coloured fibres, involved very intricately: the stem rises to about a foot and a half in height, towards the bottom is strong, round, firm, naked, and marked with alternate cicatrices, the vestiges of the former leaves; at the top divides into branches, producing many flowers, garnished with numerous scaly leaves, which stand upon long foot stalks, surrounding the middle of the stem. They are divided, as in the black hellebore, into simple leaves, commonly eight or nine, long, narrow, serrated, lanceolated, and of a dark green colour; and scaly leaves, placed at the ramifications of the flower-stem, smooth, trifid, alternate, often purplish; but those near the flowers are oval and pointed: the flowers are numerous, terminal, pendent, of a roundish shape, and stand upon peduncles, forming an umbel; the petals are five, oval, concave,

persistent, of a pale green colour, usually tinged with purple at their margins; the stamina are the length of the petals; the antheræ white; the germina three, hairy, and shaped like those of the black hellebore. The plant grows wild in many parts of England, and flowers about February. The smell of the recent plant is extremely fetid; the taste bitter, and remarkably acid: it operates as a cathartic, sometimes as an emetic; and, in large doses, is highly deleterious. It is used chiefly as a vermifuge; the dried leaves, in powder, are given from five to ten grains. A single green leaf infused like tea forms three doses for a child of seven years old; but the plant bears in summer the leaves of the former year, and one of these of a middle size is meant. The dose is usually repeated for two, and sometimes three, successive mornings; the second has commonly a greater effect than the first, and never fails in young persons to expel round worms by stool. The best form for children is syrup. For this purpose the bruised leaves are first moistened with a little vinegar, then the juice is expressed from the leaves, and made into a syrup with coarse sugar. A tea spoonful is given at bed time, and one or two in the morning, for two or three successive days, increasing or diminishing the dose according to the strength of the patient. In the western counties, a tincture is sometimes made of the leaves with cyder, and said to be an useful preparation. It probably is so, if, as has been asserted, vegetable acids are correctors of this plant. In whatever way, however, it is employed, no medicine acts with more certainty than bear's foot as an anthelmintic. It always evacuates the round worms, but is less effectual in ascariides and tenia. Dr. Bisset speaks of the plant as also useful in some asthmatic and hypochondriacal disorders. See his Essay on the Medical Constitution of Great Britain. The powder also sprinkled on issues increases their discharge. See Tournefort's *Materia Medica*. Raii *Historia Plantarum*.

HELLEBORUS ALBUS. *Veratrum*; COMMON WHITE HELLEBORE. *Veratrum album* Lin. Sp. Pl. 1479. This plant hath large, oval, ribbed leaves, placed alternately on a round stock, which they embrace by a tubular basis; in their axillæ towards the top appear clusters of hexapetalous, greenish white, flowers, followed each by three flat pods, containing whitish triangular seeds: the root is short, commonly near an inch thick, with numerous fibres hanging from it, externally of a brownish colour, internally more white. It is common on mountainous places in Germany and Switzerland. Our hellebore is probably not the same with that of the ancients, which seems, from the synonyms in Caspar Bauhine's *Pinax*, to be a species of anemone. Tournefort supposes his *helleborus niger orientalis amplissimo folio caule præalto flore purpurascente* to be the hellebore of the ancients, as he found it in the island of Anticyra, famous for the production of this medicine.

When the root of white hellebore is fresh, it hath a disagreeable smell, which is lost in drying; and a nauseous, bitterish, acrid, penetrating, and durable taste. When powdered it is used externally in cuticular eruptions, and particularly the itch; but if applied to any sore it excites vomiting, and other disagreeable symptoms: snuffed up the nose it proves a violent sternutatory. If the powder be taken from x. to xv. grains, it

operates powerfully upward and downward; but except in maniacal cases it is rarely used. If, on taking this root, it does not operate freely, an emetic will evacuate it; otherwise convulsions will probably follow. Hoffman observes that it affects the fauces, producing strangulation and danger of suffocation, with great anxiety; which the juice of quinces will in his opinion relieve. Gesner infused half an ounce of this root in two ounces of water, two drachms of which produced considerable internal heat about the tongue, the throat, the head, and breast, followed by singultus and vomiting. It produces also violent nervous affections, as vertigo, tremors, syncope, spasms, convulsions, and death. In all these instances the internal coat of the stomach appears to be inflamed. Greeding found it useful in maniacal cases, and it seemed to act on all the different secretory organs, in some cases producing inflammation of the lungs. It has been given also with advantage in epileptic cases.

Tincture of white hellebore is made by digesting eight ounces of powdered white hellebore roots in two pints of proof spirit; and it is the best internal preparation; sometimes used to quicken cathartics, in apoplectic, lethargic, and maniacal cases. In chronic disorders it might be employed to great advantage, if small doses at first were gradually increased. A grain and a half added to a drachm of sneezing powder quickens its operation. It is also used in decoction, and an ointment. *Decoction of white hellebore* is made by boiling an ounce of the root in two pints of distilled water, till reduced to one: when cold, two ounces of rectified spirit of wine are added. This is used in cutaneous diseases; but chiefly the itch, herpes, and morbus pediculosus, which it frequently cures; and is more cleanly than the ointments.

Gesner says, the root in the form of an oxymel is a powerful expectorant and aperient. It is most indisputably a very powerful medicine, and should be given at first in very small doses, gradually increasing them. It is now omitted in the *materia medica* of the London college, as highly dangerous.

HELLEBORUS NIGER; *melampodium*; by Paracelsus, *daura ectomon*; CHRISTMAS FLOWER, BLACK HELLEBORE. It is the *helleborus niger* Lin. Sp. Pl. 783. The CHRISTMAS ROSE. Melampus is said to have observed its purging quality in the goats which fed on it, and introduced it into the *materia medica*, from whence it was styled *Melampodium*; but in reality the name is derived from its black colour, and the shape of its leaves. It is a low plant, without any stalk: the leaf is divided quite to the pedicle, into six, seven, or more, smooth round segments, resembling bay leaves, indented from about the middle to the extremity: the flower is large, naked, pentapetalous, of a pale rose colour, with numerous stamina in the middle, followed by five or six pods full of shining black seeds; the petala continuing and changing greenish: the root consists of numerous fibres, hanging generally from a knotty head, externally of a blackish colour, internally white. It is perennial, grows wild in the mountainous parts of Germany and Switzerland, and flowers in our gardens in January.

The root to the taste is bitter and pungent; if chewed for a few minutes it benumbs the tongue. Dr. Grew observes, that it is first felt on the tip of the tongue,

and then on its middle. The fibres are stronger and more active than the tuberous head, and the cortical part of the latter than the internal. It frequently loses its virtue by keeping; and with its smell its powers are lost.

The roots of the poisonous aconites resemble those of black hellebore; but the aconite is lighter coloured than the palest black hellebore roots. It is safe therefore to choose the darkest. In a dose of from fifteen to twenty grains it proves actively purgative.

Long coction destroys its activity; and water extracts, by boiling, and spirit by digestion, nearly all the virtue of the root. Rectified spirit takes up chiefly the irritating resinous part. After proper boiling in water it yields little to spirit; but after repeated digestion in pure spirit, it yields to water a large portion of mucilaginous matter, supposed to be diuretic.

In the present practice the black hellebore root is only used in small doses as an attenuant and deobstruent; chiefly in obstructions of the menses, when the habit is plethoric, where chalybeates would be improper. The emmenagogue virtues of this medicine are, however, doubtful; for Dr. Cullen never found them in many trials, nor had he met with any practitioners in Scotland who had better success: not one instance has occurred of the power of hellebore in producing hæmorrhage. It promotes urine and perspiration; in hypochondriasis it may be joined with chalybeates; and if the pulse be low, with the fetid gums, and a julep of volatile salt: in dropsies it is said to be useful, if joined with alkaline salts. In nervous cases which do not admit of chalybeates, its advantages are considerable; and when given so as to be powerfully cathartic, it is useful in mania. It is one of the principal ingredients in Bacher's famous tonic pills. See ASCITES.

The London college directs a watery extract, (see EXTRACT. GLYCYRRHIZÆ,) and a tincture with proof spirit, made in the following manner:

R. Rad. hellebori nigri in pulverum crassum tritæ ꝑ iv. coccinellarum in pulverem tritarum ꝑ ij. spt. vinosi tenuioris, m. ℥ ij. digere leni calore per dies octo, et cola. Pharm. London. 1788. The extract is a good and safe preparation when designed as a cathartic; and it contains also the diuretic virtue: the irritating power is in a great degree destroyed by boiling. The dose is from gr. x. to ʒ ss.; that of the powder is the same, though the extract is thought milder; but as an alterative, the tincture is usually preferred, of which a tea spoonful twice a day may be considered a common dose. See Neumann's Chemical Works. Tournefort's and Lewis's Materia Medica.

HELMINTHIASIS. A disease in which worms are bred under the skin.

HELMINTHICA, (from ἕλμις, a worm). Medicines which destroy worms.

HELOCAPO'LLIN. A sort of cherry. See CAPOLIN MEXIC. HERNAN.

HELO'DES, (from ἕλος, a fen). An epithet of fevers, generated from marsh miasma, attended in the beginning with profuse but not salutary sweats. The *sudor Anglicus* is of this kind. See TYPHODES.

HELO'SIS, (from εἰλω, to turn). A disorder of the eye, consisting in an eversion or turning up of the eye lids.

HELO'TIS. See PLICA POLONICA.

HE' LXINE, (from ἕλκω, to draw; so called because it sticks to whatsoever it touches). See PARIETARIA.

HEMALO'PIA, for HÆMALOPIA; q. v.

HE'MERALOPS, (from ημερα, a day, and ὤψ, the eye,) by Rhazes *dorea*. A defect in the sight, which consists in being able to see in the day only, but not in the evening. See NYCTALOPS.

HEMEROCA'LLIS, (from ημερα, day, and καλος, beautiful; because its flower opens in the day and shuts at night). See LILIUM RUBRUM.

HEMICERAU'NIOS, (from ημισυ, in composition, ημι, half, and κειρω, to cut; because it was divided half way down). The name of a bandage, in Galen, for the back and breast.

HEMICRA'NIA, (from ημι, half, and κρανιον, the skull). See CEPHALALGIA.

HEMICRA'NIA LUNA'TICA. An erratic fever.

HEMINA, (ημινια,) an ancient measure which differed in its contents. That used in medicine was equal to about ten ounces.

HEMIOBO'LION, or HEMIO'BOLON. Half an obolus, or the twelfth part of a drachm; equal to five grains.

HEMIO'LION, is, according to Galen, twelve drachms; and in another sense it is the same as sesquialtera, the whole of a thing and half as much more, as sesquiuncia; sescuncia an ounce and a half.

HEMIONI'TIS, (from ημιονος, a mule; because, like a mule, it is sterile). MULE'S FERN. *Hemionitis lanceolata* Lin. Sp. Pl. 1535. It grows in Italy; resembles the hart's tongue in appearance and virtues. See LINGUA CERVINA.

HEMIO'NIUM, (from the same; because it is supposed to make women steril, like the mule). See ASPLENIUM.

HEMIOPSIA, (from ημισυ, half, and σκοπαι, video). An affection of the sight, in which a person sees only half the object.

HEMIPA'GIA, (from ημισυ, half, and παγιος, fixed). See CEPHALALGIA.

HEMIPLE'GIA, HEMIPLE'XIA, (from ημι, half, and πλησσω, to strike). Dr. Cullen arranges it as the second species of paralysis, in which one side of the body only is affected: of this he mentions two varieties. 1. When it occurs in plethoric, and 2. when in leucophlegmatic habits. It usually begins with, or follows, a paroxysm of apoplexy; and when the hemiplegia, after subsisting for some time, becomes fatal, it is commonly by passing again into the state of apoplexy. The relation, therefore, between the two diseases is sufficiently evident, and is further strongly confirmed by the hemiplegia coming upon persons of the same constitution, and being preceded by the symptoms of apoplexy. See PARALYSIS. London Medical Journal, vol. i. p. 323; vol. ii. p. 198.

HEMIRHO'MBION, HEMITO'MON, (from ημισυ, half, and ἱεμῶ, to revolve; or τεμνω, to cut). A bandage mentioned by Hippocrates, called *semirhombus*, from its extending half way round the part to which it is fixed; and *hemitomon*, from its being cut half way down.

HEMISPHERA. Half of a globe applied to each half of the brain.

HEMITRITÆ'US, (from *ἡμισυ*, *half*, and *τετάρτος*, *third*, or *tertian*). See SEMITERTIANA FEBRIS.

HE'PAR. HE'PER. Martinius and Gorræus derive it from *ερα*, *to work*, and *ερα*, *blood*; supposing its office was to prepare the blood. It has been also derived from the Hebrew *chebar*, *gall*. THE LIVER. See JECUR.

HE'PAR. SU'LPHURIS. - A sulphuret prepared by adding sulphur to a fixed alkali, chiefly employed in medicine as a counterpoison of hydrargyrus muriatus and arsenic. When an acid is added, the gas which escapes is called *hepatic*, and it is the peculiar ingredient in the Harrowgate water, to which its smell is owing. Three parts of filings of iron, and two parts of sulphur, mixed, separate a similar gas, which is only hydrogenous gas, containing sulphur in solution.

HE'PAR. UTERI'NUM. See PLACENTA.

HEPATA'LGIA, (from *ἥπαρ*, *the liver*, and *αλγος*, *pain*). When pain affects the liver, as well as spleen, it is not often easy to distinguish them from bilious colic during the life of the patient: some practitioners think it unnecessary, since they require the same method of cure; but as they arise from different causes, it may not be useless to describe some of these; viz. scirrhusity of the liver; obstructions of the gall ducts, from very viscid bile; and biliary calculi.

When pain of the liver owes its origin to scirrhusity, it is attended with a tumour and hardness on the right side below the short ribs; a sense of weight, with a constant dull and tensive pain; difficult breathing; a dry cough; a sense of weight on the stomach after eating, with an increase of the difficulty of breathing; uneasiness from lying on the left side; the countenance yellow, or pale, and sallow; and the urine often of an orange colour, depositing a thick mucous sediment. If the complaint continues, as is too frequently the case, the feet swell, the body is emaciated, a dropsy of the belly, with a remittent fever, comes on.

When the cause is obstruction of the gall ducts, from viscid biliary matter, the symptoms of a scirrhus liver, which comes on in the beginning, are much slighter; to which are added a flushing heat of the face, with occasional redness and heat in the palms of the hands; an irregular thirst; dryness, and bitter taste in the mouth; a dry cough; viscid saliva; loss of appetite; heart burn; weariness and heaviness of the limbs; increase of pain on touching and pressing the left side, or the pit of the stomach; and costiveness. The hardness on the right side is not so firm as in the former case, nor do the œdematous swellings, or hectic symptoms, appear.

When it arises from gall stones, there is a deep seated and excruciating pain on the right side, or at the pit of the stomach, extending through the body to the back, not constant, but occasionally violent, and attended with faintness, sickness, and often vomiting: the patient complains of sickness; the right side and the epigastrium are tense; the belly costive; the excrements pale and whitish; the pulse weaker, but seldom quickened, even when the pains are very violent and continued. The violent pain without fever, or quickness of the pulse, is considered as the certain symptom of this disease. The patient, either in an erect posture, or laying on the left side, feels very uneasy; is restless; breathes with difficulty; is affected with heart burn, and sometimes

convulsions. The urine is pale, afterwards yellow; and the skin and white of the eyes have a jaundice-like appearance: the pain at last vanishes suddenly, a looseness sometimes succeeds, by which the gall stones are discharged, and the yellowness disappears.

Pain in the liver from scirrhusity is apt to attack gluttons; hard drinkers; and those who have led indolent lives. It also arises from suppression of hæmorrhages, bruises upon the right side; general concussions from falls; and very often from long continued intermittent fevers. The disease generally proves fatal, when once formed; though, if attended to in the beginning, it might perhaps be prevented.

When scirrhus liver or viscid hepatic obstructions arise from hard drinking, we have explained its effect from ardent spirits destroying the irritability of the vessels; a change most severely felt, where the circulation is languid, and unassisted by the muscular coats found in arteries. The suppression of hæmorrhages throws the blood, as we have seen, on the internal parts; and in elderly persons, where this effect is chiefly conspicuous, the disease equally arises from a want of irritability in the vessels to propel the accumulated contents. When it is owing to general shocks, we have explained its action in the article CONCUSSIO, q. v.

Decoctions of vegetable aperients, as grass roots, and dandelion, are serviceable. Gum ammoniacum and myrrh have been recommended on the vague principle of attenuating; but the effects of these remedies are inconsiderable. We must chiefly depend on some stimulant which will act with steadiness on the minuter vessels, and this property is almost exclusively confined to mercury, assisted with the decoctions of guaiacum and mezereon. Small doses of calomel may be given, or, what is preferred, mercurial ointment may be rubbed in on the part affected. At the same time the circulation in the liver may be assisted by gently stimulating the excretory ducts of this organ by rhubarb, or the cathartic mineral waters. Chalybeates are also useful, and they are combined in the present fashionable remedy, the Cheltenham waters. Bath waters, in gouty habits; and when the disease has arisen from long residence in warm climates, are occasionally beneficial.

When spasmodic affections are the cause, which is known from their succeeding violent passions, sedatives and antispasmodics, as asafoetida, camphor, or opium, may be joined with the aperients; and when by these means the obstruction is removed, bitters and steel will complete the cure. In its course, however, the body must be kept open.

When the disease arises from gall stones, we must endeavour to promote their expulsion by the continued use of emollients and gentle cathartics, with warm bathing, interposing opiates.

Bleeding is sometimes premised to prevent inflammation in strong plethoric habits, and vomits are often useful; but they increase the pain, and are suspected of occasioning inflammation. If, however, they can be borne, they greatly facilitate the passage of a gall stone. As a combination of ether and spirit of turpentine has been found to dissolve gall stones out of the body, the same medicine has been recommended internally. We can scarcely understand how it can reach the object; but it has been said to have been useful.

In order to prevent a return of these complaints, gentle exercise, particularly riding on horseback, should be persevered in; light, easy digestible food taken, avoiding all that is viscid.

The hepatalgia, however, has not been established as a genus by the latest and best nosologists; nor should any such be included in a regular system, for the distinguishing symptom, pain, is often absent; and we thus include diseases very different, viz. infarcted and scirrhus liver, chronic hepatitis, and jaundice from all its various causes. In this, as well as many other instances, we have not been able to alter the former arrangement, without disturbing numerous references, and inducing greater confusion than we should remove.

Many parts of this article will be, of course, repeated under these heads.

HEPATA'RIOUS, (from *ἥπαρ*, the liver). HEPATIC.

HEPA'TEROS, (from the same,) is an epithet for that kind of dysentery in which the discharge is of a dark yellow or sanious.

HEPA'TICA, (from the same). Belonging to the liver, is applied to medicines serviceable to the diseases of that organ; and to a pain in the region of this organ.

HEPA'TICA VULGA'RIS, *fontana, terrestris, stellata, jecoraria, lichen petræus latifolius; marchantia polymorpha* Lin. Sp. Pl. 1603. STONE, OR STAR LIVER WORT; is a species of moss growing in stony places; perennial, and running to seed in March and April. It is said to be aperient and resolvent, but is scarcely known in practice.

HEPA'TICA NO'BILIS, *trifolium aureum* and *hepaticum, hepatica trifolia, herba trinitatis, ranunculus tridentatus vernus*; HERB TRINITY, AND NOBLE LIVER WORT; *anemone hepatica* Lin. Sp. Pl. 758; is a low plant, without any stalk; the flowers are commonly blue, sometimes reddish or white, followed by white seeds. It is perennial, grows in gravelly shady grounds in Germany, and other parts of Europe; and flowers in our gardens in February or March.

This plant is esteemed a mild restringent and corroborant, and infusions of it are used as tea. Its astringency is equally communicated to water or spirit, and wholly remains in the extracts. See Lewis's *Materia Medica*. Raii *Historia*.

HEPA'TICA A'LBA. See PARNASSIA.

HEPA'TICA ARTE'RIA. HEPATIC ARTERY. As soon as this artery leaves the cœliaca, where it is covered by the pancreas, it runs to the upper and inner part of the pylorus; sending off two branches, a small one called *pylorica*, and a larger one called *gastrica dextra*, or *major*. It then passes behind the ductus hepaticus, towards the vessica fellis, to which it gives two branches, called *arteriæ cysticæ*, and another called *biliaria*, which is lost in the great lobe of the liver. Afterwards this artery enters the fissure of the liver, and joins the vena portæ, with which it runs in the capsula Glissonii, and accompanies it through the whole substance of the liver by numerous ramifications, which may be termed *arteriæ hepaticæ propriæ*.

HEPA'TICA BRA'CHII VE'NA. See BASILICA VENA.

HEPA'TICA MI'NOR VE'NA. A branch from the vena portæ ventralis; sometimes a branch of the cysticæ venæ.

HEPA'TICA STELLA'RIS. See ASPERULA.

HEPA'TICA STELLA'TA. See ASPERULA.

HEPA'TICA TERRESTRIS JECORARIA. See HEPATICA VULGARIS.

HEPA'TICÆ VE'NÆ, arise directly from the vena cava inferior, as it passes down through the posterior part of the great fissure of the liver. Sometimes one branch from the vena cava divides into these which correspond with the vena portæ. The vena cava also sends others, which correspond with the hepatic artery.

HEPA'TICO-CY'STICI DU'CTUS. That side of the body of the gall bladder which lies next the liver, is connected to that gland by a vast number of filaments which run into the substance of the liver; and among these filaments are some ducts which form a communication between the pori biliarii and gall bladder. These ducts are the most numerous about the neck of the gall bladder.

HEPA'TICUS, (from *ἥπαρ*, liver). HEPATIC; an epithet for any thing belonging to the liver. The ancients confined the word to an inflammation of the liver; but the moderns use it to signify those whose livers are, from any cause, diseased.

HEPA'TICUS DU'CTUS. See PORTE VENA.

HEPATIRRHŒ'A, (from *ἥπαρ*, the liver, and *ῥέω*, to flow). A species of diarrhœa. (See DIARRHŒA.) The other hepatirrhœas are symptomatical.

HEPATI'TIS, INFLAMMATIO HEPATIS, (from *ἥπαρ*, the liver.) AN INFLAMMATION OF THE LIVER. An inflammation may be in different parts of the liver, as in its membranes or substance; in its concave or the convex side. Inflammation in the hepatic arteries is said to cause some symptoms not unlike those of the hydrophobia. See Hippocrates *Coac. lib. cxxxix*. Aretæus de *Curatione Acutorum*, lib. i. and Trallianus, lib. i. c. xv.

Dr. Cullen places this disease in the class *pyrexia*, and order *phlegmasia*, and defines it a febrile affection, attended with tension and pain of the right hypochondrium, often pungent, like that of a pleurisy, but more frequently dull, or obtuse; a pain at the clavicle, and at the top of the right shoulder; much uneasiness in lying down on the left side; difficulty of breathing; a dry cough; vomiting; hiccough. Sauvages and Sagar, he says, amongst the symptoms have placed a yellow colour of the face, of the urine, of the serum of the blood, and of the eruptions, which appear on the skin: but these symptoms of a regurgitation, and reabsorption of the bile, have been, he thinks, very properly omitted by Linnæus and Vogel; because such symptoms occur very rarely. Of this disease he makes two varieties, the acute, and the chronic. The pathognomonic symptoms of the first are above recited. The chronic often affords no signs by which it can be distinguished. It may, however, be suspected from some causes of the hepatitis having preceded; from a sense of fulness and weight, or from occasional pain in the right hypochondrium; from pain, on pressing the same part, or from lying down on the left side; and lastly, from a slight fever occasionally appearing.

Dr. Saunders, with great reason, supposes it owing to an inflammatory state of the system of the vena portæ; while the acute kind is owing to the same state of the hepatic artery.

Winslow thinks the seat of the inflammation is in the ramifications of the vena portæ, or the hepatic artery; Dr. Heberden that the liver is never primarily affected; and Dr. Cullen that the inflammation is only in the extremities of the hepatic artery.

The acute hepatitis may be seated either on the convex or on the concave side of the liver. In the former case, a more pungent pain and hiccough may be produced, and the respiration is more considerably affected. In the latter the pain is less, and a vomiting attends from the communication of inflammation to the stomach. The inflammation of the concave surface of the liver may be readily communicated to the gall bladder and bilious ducts; and this perhaps is the only case of idiopathic hepatitis attended with jaundice.

The disorder is most frequent in warm climates; it is produced by the common causes of internal inflammation, and is then preceded by fever, and by obstruction of the hepatic ducts. Hepatitis is sometimes communicated to the liver from the lungs, and it then follows peripneumony, and is apparently an exacerbation of the same disease, communicated to the adjoining membranes. Its remote causes are uncertain.

When the seat of the disorder is in the membranes, the pain is more acute, and resembles a pleurisy more than when the substance of the liver is the part affected. In this acute kind, the pain is pungent; the fever very considerable; the pulse frequent, strong, and hard; the urine high coloured.

In general, when the substance of the liver is inflamed, the pain is not very acute at first; but gradually increasing, it shoots up to the top of the right shoulder, and sometimes into the throat and about the clavicle. The pain darting into the throat is said to be a pathognomonic symptom. The pulse is not much altered in the beginning, if the disease be not very acute; and often inflammation is only known to have existed by the abscess. When the convex part of the liver is affected, a tumour is visible externally, and occasions a cough and a difficulty of breathing: the pulse is then quickened, and the patient cannot well lie on his left side. In all cases of inflammation in this viscus, the quantity of the bile thrown into the duodenum is increased, and the evacuations become bilious.

Dr. Cullen observes, that the acute hepatitis may be known by a pain in the right hypochondrium, increased by pressing upon the part. The pain is very often so pungent as to resemble that of a pleurisy; frequently, as in pleurisy, is increased on inspiration, and the patient can then only lie on the side affected. The disease is sometimes also attended with a cough, commonly dry, but sometimes followed by expectoration.

Inflammation in the liver when highly acute is short, and terminates by resolution; but when less active it more generally ends in suppuration, and proves fatal by inducing hectic, unless the matter can be discharged externally. If properly treated in the beginning, it is rarely mortal.

The resolution of the hepatitis is often the consequence of, or is attended with, evacuations of different kinds. A hæmorrhage, sometimes from the nose, sometimes from the hæmorrhoidal vessels, relieves the disease. More commonly, a bilious diarrhœa or external erysipelas contributes to the same event; and the resolution of the hepatitis, as of the other inflam-

mations, is attended with sweating, and with an evacuation of urine, depositing a copious sediment.

This kind of inflammation should be distinguished from inflammation of the pleura, of the diaphragm, of the stomach, of the muscles of the belly, and from spasmodic pains-

Inflammation of the pleura, or lungs, so often precedes or accompanies hepatitis, that the distinction is difficult, and fortunately of no great importance, as the same means of relief are employed. The incessant vomiting distinguishes inflammation of the stomach; but that of the diaphragm is often confounded with hepatitis, and sometimes accompanies it. The pain across the body is not easily distinguished from the shooting pain from an affection of the gall ducts; and it is not yet ascertained that either delirium or the risus sardonius is the peculiar symptom of diaphragmitis.

These symptoms in the beginning do not often alarm the patient; and early assistance is not always demanded. At any period before the fifth day, bleeding may be employed; the operation repeated if the pain is considerable, the patient young, strong, and plethoric. After a free bleeding, a large blister should be laid over the part affected; and if there is a free passage for the bile into the duodenum, the bowels kept freely loose with proper doses of antimonium tartarizatum, infusion of tamarinds, vitriolated natron, and rhubarb.

Dr. Curry, combining these ideas with the East Indian practice, which is not well adapted for the more acute hepatitis of this climate, recommends calomel as the most active laxative, and particularly adapted for emulging the glands of the diseased part. When it is rejected from the stomach, he advises washing it with lime water, and giving the powder which remains, joined with opium. In the very irritable state of the stomach which sometimes accompanies the disease, this form of mercury is, he thinks, more easily borne.

If these means fail, or if it is too late for their proper use, and symptoms of a beginning suppuration appear, the powder of bark in the dose of $\bar{3}$ ss. four or five times a day may be given, and the quantity increased until $\bar{3}$ ss. is taken every twenty-four hours.

If the abscess points externally, it must be encouraged by maturing cataplasms, and opened as soon as possible, particularly if, from its immobility, the liver seems to adhere to the peritoneum; and the bark may then be given to two ounces in twenty-four hours, if the stomach will retain it, and we may thus proceed until suppuration appears. If, from purulent or ichorous stools, it is evident that the abscess has burst into the duodenum, or, from other symptoms, that it hath discharged its contents into the cavity of the belly, the same methods may be used, though equally good effects cannot be expected.

Hepatitis, however, has lately pressed on our notice in very different forms, in consequence of our more extended connections in India. In hot countries, where the circulation is more languid, the liver particularly suffers from any cause of fever, nor can its infarctions be removed by the usual methods of blisters and laxatives. A medicine which gives tone and activity to the circulating system is necessary, and this medicine is mercury. Even in the early stages of the complaint it is administered both internally and exter-

nally, and the limits of its employment are the appearances of its action on the sanguiferous system, by the effect on the gums. Very large quantities, it is said, are often administered before this effect is produced; but as soon as it appears, all the symptoms are relieved.

The long residents in hot climates bring back to this country all the symptoms of chronic hepatitis, with a variety of complaints arising from an infarcted liver, which have apparently little connection with this disease. The peculiar symptoms of chronic hepatitis are, irregular fever, indigestion, costiveness, white stools, swelled legs, the complexion of a sallow yellow, pain or fulness of the hypochondria, dry cough, disturbed sleep, and dejected spirits. Many of these appearances are, however, sometimes wanting; and occasionally the cough only, indigestion, or irregular fever, are observed: but, in every instance where the patient has resided long in a warm climate, a diseased liver may be suspected; and whatever the complaint be, the state of the liver should be examined; and if fulness or tension, if pain or uneasiness, be felt, or experienced on pressure, the appropriate remedy, mercury, must be employed, to which gently stimulating laxatives must be added.

Powerful astringents are less useful than what are styled the aperient bitters, viz. the camomile flowers, columbo root, and quassia, which should be taken in moderate doses, continued for some time; and their use after a little intermission resumed. The Bath waters, formerly so much commended in this complaint, have yielded in credit to those of Cheltenham, whose laxative power is highly useful, and rendered less debilitating than it might otherwise prove by its chalybeate impregnation. Constant but moderate exercise; free air; cheerful society; frequent changes of scene, and tepid sea baths; are generally useful: but all our attempts relieve only—lateri adhæret vulnus!

See Pringle on the Diseases of the Army. Fordyce's Elements, part the second. Matthews on Hepatic Diseases. Cullen's First Lines, vol. i. p. 376, edit. 4. Bell's Surgery, b. v. p. 387. London Medical Transactions, vol. ii. p. 147. Saunders on the Liver; and Pemberton on Diseases of the Abdominal Viscera.

HEPATIZON, (from *παρ*, the liver, because it is of a liver colour). See MORPHEA.

HEPATOCE'LE, (from *παρ*, and *κρη*, a rupture). RUPTURE OF THE LIVER. This complaint happens from the liver passing through the relaxed parietes of the abdomen, in the vicinity of the umbilicus, or through the umbilicus itself. This disease may be distinguished by tracing the liver to the part which the tumour occupies; from the parenchymatic firmness of the protuberance, which is sometimes livid; from the absence of those symptoms which point out the enterocœle, epiplocele, gastrocœle, and particularly the hysterocœle. The species are distinguished by the situation of the tumour into hepatocœle ventralis and umbilicalis. The mode of cure is similar to that of other ruptures, particularly the GASTROCELE; q. v.

HEPATO'RIMUM, (from *παρ*, the liver). See EUPATORIUM.

HEPATO'RIMUM AQUA'TILE. See BIDENS.

HEPSE'MA, (from *ἵψω*, to boil). A DECOCTION. See MUSTUM.

HEPTA'NDRIA, (from *ἑπτα*, seven, and *ανηρ*, a husband). The seventh class of Linnæus's system, including plants which have seven stamina.

HEPTAPHA'RMACUM, (from *ἑπτα*, seven, and *φαρμακον*, a medicine or remedy). A plaster or ointment, containing seven ingredients, viz. litharge, wax, colophony, fat, &c.

HEPTAPHY'LLUM, (from *ἑπτα*, seven, and *φυλλον*, a leaf). See TORMENTILLA.

HEPTAPLEU'RON, (from *ἑπτα*, seven, and *πλευρα*, a rib, furnished with seven ribs). See PLANTAGO LATIFOLIA.

HERACA'NTHA. See CARLINA.

HERA'CLEA, (from *Heraclea*, the city near which it grew). See MARRUBIUM AQUATICUM.

HERACLEI'OS, or HERACLEI'US. HERCULEAN. Names of epilepsy, mania, and loadstone; from the great strength and power exerted.

HERACLEO'TICUM, brought from *Heraclea*. See ORIGANUM.

HERA'CLIUM OLEUM; supposed to be the oil of box wood.

HERA'CLIUS LAPIS. See MAGNES.

HER'BA, (from the Arabic term *erbah*, from *rabah*, to germinate). HERBS, or PLANTS whose stalks die to the ground every year: Those whose roots continue one year are called *annual*; if two years, *biennial*; and if durable, *perennial*. In common language, an herb is used in opposition to a tree. By Linnæus the herb is put for that part of a vegetable which arises from the root, is terminated by the fructification, and comprehends the stem, leaves, fulcra, and hybernacula.

Herbs are to be gathered when the leaves are at their full growth, before the flowers unfold, except those whose flowery tops are preferred. They should be quickly dried, in a room heated by a fire to a degree equal to the hottest day, from 75° to 80°. Aromatic plants should be collected from warm dry soils; fetid ones from those which are moist and rich. All herbs and leaves should be gathered in clear dry days, as soon as the morning dew is dissipated. When herbs are properly dried, they are good while their colour remains, both for decoctions and distillation; those that are good when dry are preferable to the same herbs in their green state.

HER'BA PA'RIS, (from the Trojan youth,) this herb bearing but one seed; *uva lupina, solanum quadrifolium*, HERB PARIS, HERR TRUE LOVE, or ONE BERRY. *Paris quadrifolia* Lin. Sp. Pl. 527. It is a low plant; grows wild in shady woods; flowers in April and May; the berry is ripe in July. Gesner observes, that its juice is narcotic; but it is not now used. See Raii Historia. For the herba Paris alba, see ABSINTHIUM VALESIIACUM.

HER'BA ALEXANDRI'NA. See HIPPOSELINUM.

HER'BA BENEDI'CTA. See CARYOPHYLLATA.

HER'BA BRITANNICA. See HYDROLAPATHUM.

HER'BA FE'LIS. See MENTHA CATARIA.

HER'BA JU'LIA. See AGERATUM.

HER'BA MELANCHOLI'FUGA. See FUMARIA.

HER'BA PE'TRI. See PRIMULA VERIS, under PARAPLYSIS.

HER'BA RE'GIA. See BASILICUM, and ARTEMISIA.

HE'RNA SA'NCTÆ BA'RBARÆ. See BARBAREA.

HE'RNA SA'NCTI PE'TRI. See CRITHNUM.

HE'RNA STE'LLA. See CORONOPUS.

HE'RNA TRINITA'TIS. See HEPTICA NOBILIS.

HE'RNA VETE'RIBUS IGNO'TA. See CARDAMINES.

HE'RNA VI'VA. See CAACO.

HERBA'TUM CANADE'NSIUM; *panaces moschatum*; SWEET SCENTED ALL HEAL OF AMERICA. *Aralia racemosa* Lin. Sp. Pl. 393. This plant is found in Canada; but is rather alimentary than medicinal.

HE'RCULEA MEDICAMENTA. Named from their supposed extraordinary powers.

HE'RCULES BO'VII. The name of a once famous emetic and cathartic preparation.

HERMA'NNIA. Denominated in honour of HERMAN BOERHAAVE. The name of an African genus similar in virtue to the marsh mallows. None are used in medicine; but if any have a claim to notice, it is the *hermannia althæifolia* Lin. Sp. Pl. 141.

HERMAPHRODITUS, (from Ἑρμης, Mercury, and Ἀφροδιτη, Venus). AN HERMAPHRODITE; *andria*; a person supposed to be of both sexes; but the clitoris of a woman being of an extraordinary size, is all the peculiarity in this supposed species of the human kind. (See Cheselden's Anatomy.) In botanical language it is applied to flowers having both anther and stigma. Hence an hermaphrodite plant is that which has only hermaphrodite flowers.

HERMETICA MEDICINA. HERMETICAL MEDICINE, is the medical system adopted by the chemists, at present deservedly exploded and forgotten.

HERMETICUM SIGILLUM, the securest means of inclosing fluids in a glass tube, viz. by melting the neck, and closing or twisting it with a pair of pincers.

HERMODA'CTYLUS, (from *Hermus*, a river upon whose banks it grows, and *dactylus*, a date, which it resembles). *Hermodactyl*; *colchicum illyricum* of Forskell and Gronovius; *alsurengium*; *asaba*; *Hermes dactyletus*; *ephemeron*; is the root of a plant brought from the east; of the shape of a heart, and of a reddish, yellowish, brownish colour. When white and hard it is preferred. Each root is flatted on one side, with a furrow on the other. Though known from the time of Prosper Alpinus, it is singular that its species has not been accurately ascertained. It is highly probable that it is from the plant which furnishes the following medicine. It hath a viscous farinaceous sweetness to the taste, but no smell. The ancients say it is cathartic; but the dried ones which we receive are perfectly inert. Prosper Alpinus informs us, that the Egyptian women eat them as a means of becoming fat. They are not of any known use in medicine. See Lewis's *Materia Medica*. Neumann's *Chemical Works*.

HERMODA'CTYLUS FO'LIO QUADRA'NGULO, called also *iris tuberosa*, *iris bulbosa*, and SNAKE'S HEAD IRIS; *iris tuberosa* Lin. Sp. Pl. 58. The root of this plant hath a tubercle, which is both emetic and cathartic.

HE'RNA, (from ἔρνος, a branch, because it protrudes forward). A TUMOUR, *ecrexia ramex*, and a RUPTURE, as occasioning a tumour. In consequence of some sudden effort, a portion of the contents of some cavity is forced through the interstices of the containing parts, usually confined to the abdominal contents forced

through the interstices of the abdominal muscles, or those openings designed for the passage of nerves and blood vessels. Dr. Cullen defines it an ectopia, or displacing of a soft part, though still covered with the skin and other integuments.

From the situation of these tumours, their contents, or both, they obtain their respective denominations; occasionally taking their name from attending circumstances. 1. Those from the situation are the umbilical, femoral, labial, scrotal, or ventral. 2. Those from the contents are the enterocele, epiplocele, entero-epiplocele, pneumatocele. 3. Those from attending circumstances are, the incarcerated hernia, &c. True and false hernia have been distinguished; but each is a tumour of the scrotum, and the former are from the abdominal viscera, beginning from above and descending downwards to the groin or scrotum; while the latter begin from below and ascend upwards; as the hernia humoralis, hydrocele, hæmatocele, and sarcocele. These are diseases in the part where the tumour appears; from the Greek term *ελην*.

The inguinal is the most frequent hernia; and the next to this is the femoral. The umbilical seldom occurs except in elderly women, who have been often mothers. A hernia of any other viscus, besides the intestines, is peculiarly rare.

When the intestines fall down from the cavity of the abdomen, or rather of the peritonæum, it is evident that this latter membrane must be carried with them, unless it should be ruptured or wounded, which is seldom the case. When independent of wound, the gut usually falls through those apertures, originally formed for the passage of the spermatic cord; and in women of the round ligaments of the uterus, or for the femoral arteries. These apertures are imperfectly closed with fat only; for they are not muscular, and therefore do not admit of contraction. It sometimes, however, happens that the intestine is forced through the fibres of the abdominal muscles; and one case is recorded in which the colon was pushed through the fibres of the diaphragm; in others, the intestines have passed by the side of the œsophagus, by the vena cava inferior, or more rarely by the aorta into the thorax; the general cause is whatever contracts the capacity of the abdomen, or violently forces the intestine against the apertures mentioned. Violent coughing, crying, laughing, costiveness, dysury, pregnancy, or whatever produces a deep inspiration, occasions this contraction, by the united exertions of the diaphragm and abdominal muscles. Suddenly lifting a heavy weight, which produces a deep inspiration, the jumping of a rough horse, and any other violent exertion, have been followed by the same consequences. Independent of these causes, in weak persons the weight of the intestines will produce a similar effect. It is, therefore, common in warm climates; after long fevers in old persons; those who, with poor diet, have laboured hard; and it has been said, that those who eat large quantities of oil are subject to this complaint. This, however, can scarcely happen but in the warmer regions; and increased temperature alone predisposes to it. Hernia sometimes appears to be hereditary.

There are other apertures through which the intestines sometimes, though very rarely, pass; as between

the bladder and rectum, or the uterus and rectum, when the tumour appears in the perinæum; by the ischiatic notch; or by the side of the sciatic nerve, when they are seated under the glutæi muscles. Mr. Cooper mentions a singular hernia, where the intestine passed into the labia pudendi, falling under the branch of the ischium along with the internal pudendal artery, but continued into the pelvis, by the side of the vagina. In one case they passed between the laminæ of the peritonæum into the mesentery; and, in another, into a bag formed by a separation of the laminæ of the mesocolon. When the formation of the muscles is defective, the intestines may even protrude at the loins.

Other viscera are occasionally displaced. The brain is sometimes protruded through the skull, when the bones of the head are deficient; the lungs will occasionally pass through the fibres of the intercostal muscles; and the uterus or bladder has been protruded through the parietes of the abdomen. These herniæ are, however, uncommon.

The sac which contains the intestines is, therefore, the peritonæum, and the contents are most commonly the omentum and the ilium; less frequently, in succession, the colon, the cæcum, and the jejunum: sometimes only the appendix cæci vermiformis. The peritonæum in this situation is generally thickened; though, when the weight has been considerable, it has been found peculiarly thin. The rupture of the peritonæum, which was supposed always to happen, and which gave a name to the disease, rarely occurs. The sac, however, has occasionally burst, particularly in one instance, by a blow; and where the intestines escape, from defective organization of the muscles, they are seldom in a sac, for the peritonæum also is usually defective in the corresponding portion. The hernia congenita and hernia cystica are equally destitute of the peritonæal covering; and, in one instance, the umbilical hernia was without it, a circumstance which should suggest extreme caution in the operation. The size of the sac differs from different circumstances, chiefly from the duration of the disease. The symptoms, however, are not in proportion to the size. We have seen the most violent ones occasioned by a rupture not equal in size to a filbert.

In general there is a pain and uneasiness in the tumour; and, when it has been long down, the pain is often extremely violent, felt not only in the tumour itself, but over the whole abdomen. If the discharge of fæces is suppressed, inflammation soon comes on, the gut is thickened, the aperture through which it passed becomes too small for its return, and what is called a strangulation ensues. Herniæ are consequently divided into reducible, irreducible, and strangulated. Reducible herniæ are those in which the intestine on lying down spontaneously returns into the abdomen, or, at least, with the assistance of very gentle pressure, and may be retained there by the bandage styled a truss. Herniæ are often irreducible from their size in consequence of inflammation; from the intestines containing hardened fæces, or flatus, which, from some obstacle at the ring, cannot be forced back. Sometimes membranous bands form across the sac, preventing the free motion of its contents; or the intestine is united by adhesions to the side of the sac. In each case the hernia is irreducible. The reducible hernia is more subject to stran-

gulation than the irreducible; but the latter is much exposed to accidents, which are soon fatal.

The strangulated hernia is a disease of the greatest danger. When the omentum only comes down, the symptoms are those of inflammation and mortification. In this case it seldom happens that the fæces are retained; yet we have seen inflammation communicated from the prolapsed omentum to the intestines, and produce all the symptoms of complete hernia. In general, however, the pain and tension are not so great; the hiccough is less violent and constant. When the intestine, as well as the omentum, is strangulated, a violent pain is felt in the tumour, and a stricture round the body, about the navel, or somewhat above; frequent vomiting follows, succeeded by the evacuation of fæculent matter. All evacuation downward is checked; the pulse is quick, and at first hard; the tumour red and painful, often œdematous; the abdomen tense and sore; hiccough soon follows; great anxiety appears in the countenance; the pulse sinks; and the patient appears to be expiring. Yet these violent symptoms will diminish, though the disease remain unchanged; and a flattering remission will come on, again to be succeeded by the distressing symptoms just described. These, at last, appear to yield almost suddenly: the patient is apparently easy, but the abdomen becomes more tense, the tumour of a darker colour; and death soon follows.

The symptoms of the true herniæ apply in a considerable degree to prolapsed intestines in every part; and when we consider, in this detail, symptoms of prolapsed intestine, we shall scarcely fail to recognize the appearances wherever the accident happens; if, with these, we combine the injured functions of the part, and the chances of the intestines escaping into the cavity of the organ affected. See BUBONOCÈLE.

This accident being unattended with any division of the containing parts, the whole of the disease must be considered as a change of situation of the parts within. Were these immediately returned and kept in their place, the disorder would entirely cease; but in that preternatural situation they are pressed upon by the tendons through which they pass, and inflammation, with mortification, supervenes. This, however, is not owing to any change of state in the tendons, but merely to their natural elasticity, acting upon an increased and yielding subjacent bulk. The obstacle to the reduction of the prolapsed contents is, therefore, the increased bulk which they have acquired from inflammation in consequence of stricture, by which they are incapable of returning through the same passage at which they escaped.

If assistance is called in time, the return of the protruded parts must be attempted by such means as produce a contraction of the vessels and diminish the bulk of the solids: viz. cold, astringent, and stimulating applications. Emollients cannot relax the tendons, but often enlarge the bulk of the hernia, and render its reduction more difficult. Cold astringents should be immediately applied, and cold itself is an useful remedy. Ice, iced water, cold produced by the evaporation of vinegar and ether, are highly useful applications: at the same time these may be assisted by gentle but continued compression on the part with the fingers, or with small bolsters of soft linen cloth. By continuing these

efforts for some time, the vessels are visibly less diminished, the swelling grows flaccid, the stricture gives way, and the disorder is removed.

When all proper attempts fail to reduce the contents of an hernia, the sooner the operation called *celotomia* is performed (see *BUBONOCELE*), the better; but when there are evident signs of the intestine being in a mortifying state; when the pulse and countenance sink; and when the tumour has lost its elasticity; Mr. Gooch recommends making an incision into the tumour, ample enough to evacuate the *fæces* freely, which may effectually remove the strangulation of the intestine at the abdominal ring, and then to treat the wound as a mortification, allowing nature to throw off the mortified slough. If it is doubtful in what condition the parts contained in the tumour are, the operation must be cautiously proceeded on, till we can see the state of the intestine: if that is mortified, it may be opened; and if the evacuation of the *fæces* do not effectually make way for the return of the parts, the abdominal ring must be opened by incision.

But, after replacing the hernial contents, to retain them requires very often the assistance of a bandage, or a proper compress. Mr. Pott observes, "All that can be done by surgery towards the cure of the hernia is, to replace the prolapsed body or bodies in the cavity of the belly, and to prevent them from slipping out again. When whatever formed the tumour is replaced, the surgeon hath done his part; the rest is nature's: whether the tendinous aperture will so contract as to prohibit a future descent or not is matter of uncertainty, and not to be known but from the event."

When a rupture happens, and is unattended with any signs of stricture, or other violent symptoms, a bandage or a truss will be the most eligible means of relief. The modes of operation when the knife is necessary will be afterwards explained.

HE'RNIA AQUO'SA. See *HYDROCELE*.

HE'RNIA BRONCHIA'LIS. See *BRONCHOCELE*.

HE'RNIA CARNO'SA. See *SARCOCELE*.

HE'RNIA CE'REBRI. A RUPTURE OF THE BRAIN; a PROTRUSION OF THE CEREBRUM, OR CEREBELLUM, through an opening of the bones of the cranium not perfectly ossified, discoverable by a protuberance, differing with respect to magnitude, figure, and place of the cranium which it occupies, covered with the common integuments, preserving their natural colour, unless a gangrene has supervened. The protuberance is soft and indolent, resisting the touch, and painful only when inflamed, usually fluctuating, surrounded at the circumference of its basis by a bony circle, which may be traced by the fingers, and discovering a defect of ossification: it is peculiar to infants, attended, at least, in the beginning, with no violent symptoms, if the tumour is small, and situated in the vertex, or sides of the head; but palsy, stupor, and convulsions come on if it be large, or if in the occiput. The disease must be carefully distinguished from a spurious aneurism, which often in infants arises from a blow, or violent pulling of the hairy scalp. Trew, and Le Dran, cured this complaint by placing thick compresses, moistened with spirit of wine, or aqua vitæ, upon the part affected, for several weeks, renewing them every twenty-four hours. See *Sauvages' Nosologia*, vol. i. p. 217. *Warner's Observations Chirurgicæ*, xi. 59.

HE'RNIA CONGE'NITA, is a rupture where the intestine and testicle are in contact. The testes are originally situated in the abdomen, just below the kidneys, and gradually descend near the time of birth through the sheath of the spermatic chord into the scrotum, each carrying along with it an external coat, which in each is the tunica vaginalis. This discovery was made by Dr. Hunter, in the year 1755, and demonstrated in his public lectures that year.

Soon after the birth of the child, the communication between the tunica vaginalis and the abdomen is obliterated by a stricture of the parts, and an accumulation of fat; but if the intestine falls very soon, these defences are not formed.

In the treatment of congenital ruptures, the management is nearly the same as in the *bubonocele*. See *Bell's Surgery*, vol. i. p. 340.

Dr. Wisberg observes, that, in his dissections, he several times found a part of the omentum or intestines adhering to the testicle in the abdomen of the fœtus, and in such cases a hernia congenita must take place. The same, he adds, will occur, when the peritonæum, in its course over the seminal vessels to the mesentery, sends off a minute process to the ilium or cœcum, and by means of it draws down the intestines on the right side, which is the common seat of the hernia congenita. See the *London Medical Journal*, vol. i. p. 376. *White's Surgery*, p. 332.

HE'RNIA CRURA'LIS. See *HERNIA FEMORALIS*.

HE'RNIA CYSTICA. See *HERNIA VESICALIS*.

HE'RNIA FEMORA'LIS, CRURA'LIS FEMOROCE'LE. This species of rupture is the same in both sexes, and formed by the falling of the omentum or intestines, or both, into the inside of the thigh, through the arch made by the os pubis and ligamentum Fallopii, where the iliac vessels and tendons of the psoas and iliacus internus muscles pass from the abdomen. (See *BUBONOCELE*.) The methods proposed for ruptures in general will often succeed; and if the operation is necessary, it is the same as for the *bubonocele*, with the difference of dilating the ligament instead of the rings of the muscles: the dilatation must be made obliquely outwards, instead of perpendicularly upwards, to avoid dividing the spermatic vessels in the male, or the round ligaments in the female; but the pressure must be made directly upwards. Authors, however, are by no means clear respecting the means of avoiding the division of the spermatic vessels and round ligaments. Indeed it seems very difficult, and almost impossible.

The directions of Mr. Borret in the *Medical and Physical Journal* are the most clear and precise. When the fascia and sac are laid bare, he observes, that Poupert's ligament is seen binding down the sac, which must be divided; but to avoid injuring the parts mentioned, he advises making a small incision between the fibres of the external oblique about half an inch above the ligament, and to pass a director *under* the ligament, and *over* the artery, on which the operator may safely cut. The stricture must then be divided inwards to the pubes, inclining Pott's knife rather obliquely downwards. See *White's Surgery*, p. 324.

HE'RNIA FLATULE'NTA. See *PNEUMATOCELE*.

HE'RNIA FORA'MINIS MA'GNI I'SCHII. In this hernia the intestines or omentum fall through the great hole of the ischium into the internal part of the thigh,

between and under the two anterior heads of the triceps muscle. It is owing to a great laxity of the ligament, and the intestine must lie behind the pectineus; so that no pressure can be employed, and no operation can be successful, because the orifice cannot be dilated, on account of the vicinity of the vessels.

HE'RNIA GU'TTURIS. See BRONCHOCELE.

HE'RNIA HUMORALIS; *inflammatio testium*; though often an inflammation of the tunica vaginalis only. Dr. Swediaur thinks that the testicle itself is never swelled, or in the least affected, in the beginning of this complaint, and that the only affected part is the epididymis. He adds, if the testicle ever swells, it is from the inflammation extending in consequence of bad treatment. It usually is owing to a venereal inflammation, though it may also happen from irritation, or external injuries; and is subject to the usual termination of inflammation.

This disease is often induced by a stoppage of the venereal gonorrhœa, not from the poison itself, but from the inflammation extending to the mouth of the excretory ducts of the seminal vesicles; in which case, brisk purgatives, if they produce a return of the discharge, are useful, for this is the quickest method of relieving the complaint. Vomits, when the constitution can bear them, are useful while the tumour is in the inflammatory state; but are best given when the inflammation begins to yield. The ipecacuanha would be as useful as the hydrargyrus vitriolatus, if its activity were equal.

Whatever be the cause, bleeding, according to the strength of the patient, is necessary; and an active purgative must follow. Goulard's saturnine water should be applied cold by means of rags folded several times, and repeated as often as they grow warm; a mixture of vinegar and brandy, or any other discutient lotion, will be nearly as effectual. (See LOTIO.) If these remedies do not succeed in a few days in removing the violent pain, or diminishing the tumour, leeches must be applied to the part; and in every stage opiates, in large doses, alternated with laxatives, given.

The patient should lie on his back, in a large room, with little external covering; and even in this state the swollen testicle should be supported. Mercury may be employed if any induration remain, but the tumour itself is wholly inflammatory, and does not require this remedy.

Thus, if the part is suspended properly, and if the patient can conform to lie much on his back, this tumour will be removed in a short time, without the usual violent pain, or the hardness remaining afterwards, which is almost the constant effect of emollients. If, notwithstanding all our care, a suppuration come on, an emollient cataplasm must be applied warm, and continued until the matter is discharged. The knife is usually preferred for opening the abscess, but great caution is necessary that the testicle be not wounded: the dressing may be the same as directed for abscesses in general. On abscess in the testicles, see Kirkland's Medical Surgery, vol. ii. p. 256.

Dr. Swediaur proposes in cases of virulent gonorrhœa to prevent this disease, that the patient avoid exposing himself to cold, violent exercise, or venery, and that he keeps the scrotum duly suspended. If hernia humoralis occurs, he attempts, first, to allay the irritation, and then to recall the poison to its former original seat.

If the pulse be quick, full, and strong, he advises bleeding immediately. If costive, a clyster should be administered, and the patient sit half an hour in a warm bath, or on a perforated chair over the steam of hot water, previously suspending his testicles. He must then go to bed; a warm dry bag truss should be immediately put on; a warm bread poultice applied to the penis; and a full dose of opium given by the mouth, or in a clyster with linseed oil. The opiate must be repeated every twenty-four hours, and the parts exposed two or three times a day to the steam of hot water. The design of the poultice to the penis, and the hot steams, is to reproduce the discharge; but though this be useful, it is not essentially necessary, for the disease is evidently not a translation of the poison, but of inflammation only. See Dr. Swediaur's Observations on Venereal Complaints. Aikin's Observations on the Preparations of Lead. London Medical Observations and Inquiries, vol. iii. p. 152.

HE'RNIA INCARCERA'TA. It is styled an incarcerated or confined hernia when the protruded intestine cannot be returned; from its adhesion, or from the bulk of its contents. The symptoms of the disease are, a swelling in the groin, and upper part of the scrotum, very painful to the touch, and resisting the pressure of the fingers; the pain is increased by coughing, sneezing, or standing upright; frequent vomiting; and a fever, with obstinate costiveness, presently comes on, which is soon fatal.

Very copious or repeated bleeding, and a proper posture, are the principal helps; the patient should be laid with his hips much higher than his shoulders, and thus by gently raising the scrotum, and a light pressure on the tumour, the intestine may return. The tobacco clyster is highly beneficial; made by infusing two drachms of dried tobacco in one pint of boiling water, for the space of ten minutes. It acts by producing nausea, and diminishing irritability. See BUBONOCELE. London Medical Journal, vi. p. 118, 259. Edinburgh Medical Commentaries, v. 270.

HE'RNIA INGUINA'LIS. See BUBONOCELE.

HE'RNIA INTESTINA'LIS. See HERNIA SCROTALIS.

HE'RNIA LACHRYMA'LIS. When the tears pass through the puncta lachrymalia, but stagnate in the sacculus lachrymalis, the tumour is styled *hernia lachrymalis*, with little propriety or precision. It is with equal impropriety called by Anel, a *dropsy of the lachrymal sac*.

If the inner angle of the eye is pressed, and an aqueous humour flows out, the disease is the FISTULA LACHRYMALIS, q. v. Kirkland's Medical Surgery, vol. ii. p. 135.

HE'RNIA OMENTA'LIS. See EPIPLOCELE.

HE'RNIA SCROTA'LIS, HE'RNIA OSCEHA'LIS, and HE'RNIA ENTEROSCHOCE'LE; also *intestinatis*, *ectoma*, *enterocele*; by Paracelsus, *crepacio*, or *crepatura*. When the omentum, the intestine, or both, descend into the scrotum, it has these appellations; when the omentum only, it is called *epiploscheocele*. It is styled a *perfect rupture*, in contradistinction to a bubonocele, which is the same disorder; but the descent is not so great. The hernia scrotalis is distinguished into the true and false; in the former the omentum, or intestine, or both, fall into the scrotum; in the latter, an inflammation, or a fluid, causes a tumour in this part, as in hernia

humoralis, or hydrocele. Sometimes sebaceous matter is collected in the scrotum; and this hernia is called *steatocele*.

HE'RNIA UMBILICA'LIS; *epiphloomphalon, omphalocele, exomphalos, omphalos*; and when owing to flatulence, *pneumatomphalos*. In this disease the omentum, intestine, or both, protrude at the navel, and it can, in general, only be palliated. White's Surgery, p. 323.

HE'RNIA U'TERI; HYSTEROCELE. Instances have occurred of the uterus being thrust through the rings of the muscles; but this is scarcely to be discovered, unless in a pregnant state, when the strugglings of a child would discover the nature of the disease. In that state, however, it could scarcely ever occur. It is the *ecrexis* of Hippocrates.

HE'RNIA VAGINA'LIS. There is naturally a deep cavity between the rectum and the back part of the uterus, from the peritoneum descending pretty low, and forming a kind of sac, in which a portion of the small intestines in the unimpregnated state lies. The intestines, by pressing occasionally against the peritoneum at this depending part, deepen this cavity, and separate the back part of the vagina from the fore part of the rectum, thus forming the tumour in the vagina, called a *hernia vaginalis*.

HE'RNIA IN VAGI'NA. See COLPOCELE.

HE'RNIA VARICO'SA. See CIRSOCELE.

HE'RNIA VENTO'SA. See PNEUMATOCELE.

HE'RNIA VENTRA'LIS, HYPOGASTROCELE. This may happen in almost any point of the fore part of the belly, but most frequently between the recti muscles, either above or below the navel; and is only to be relieved by returning the protruded parts, and preventing the recurrence of the hernia by a proper bandage. The tumour which requires this operation is seldom bigger than a walnut; so when there are the symptoms of a hernia, and yet no appearance of one in the groin, the belly should be examined. In obstinate cases of ileus, also, it is proper to examine every part of the abdomen, for the most violent symptoms may arise from a very small hernia of this kind. The stricture must be relieved by dilating the part, as in other cases; but after the operation a bandage must always be worn, as the cicatrix may be ruptured. White's Surgery, p. 324.

HE'RNIA VESICA'LIS, seu CYSTICA. In this species, the urinary bladder is the part protruded, either in the groin or scrotum, through the opening in the external oblique muscle of the abdomen; in the fore part of the thigh under Poupart's ligament; or in the perinæum. Through some of the muscular interstices of that part, the bladder has been pushed into the vagina, and formed hernial tumours of no inconsiderable magnitude. The common attendant symptoms are, a tumour with fluctuation, either in the groin, the fore part of the thigh, or perinæum. The tumour subsides on pressure, and occasions either a desire to make water, or an involuntary discharge of urine. When the swelling is large, it is necessary that the tumour should be elevated as much as possible before the urine can be discharged; but when small, and no stricture occurs, water is generally made with great ease. When this complaint is simple, and no part of the intestine has fallen down, it commonly proceeds from a suppression of urine; so that every cause of suppression ought to be guarded against;

and when no adhesions take place, if the protruded portion of the bladder can be reduced, a truss, properly fitted, should be worn for a considerable time. When the bladder cannot be reduced, while no symptoms occur to render the operation necessary, a suspensory bag to support the prolapsed parts, without producing severe pressure, is the only probable means of relief. When a portion of the bladder happens to protrude into the vagina, after reduction, future descents may be prevented by the use of a pessary; and the same means will be successful in preventing a falling down of part of the intestinal canal into the vagina: a species of rupture which now and then occurs. But should the protruded parts be attacked with pain and inflammation in consequence of stricture, so as to render the operation necessary, we must proceed, as in similar cases, to divide the parts occasioning the stricture; but if the bladder adhere to the rupture of an intestine, great caution is required, should the operation become necessary, to avoid wounding the bladder. See Le Dran's Operations. Memoires de l'Academie Royale de Chirurgie. Sharp's Operations. Sharp's Critical Enquiry. Arnaud on Ruptures. Pott on Ruptures. Gooch on Wounds, p. 427, &c. Aikin's Observations on Preparations of Lead, p. 91, &c. Bell's Surgery, vol. i. p. 369 to 377.

HERNIA'RIA, (from *hernia, a rupture*). RUPTUREWORT; (from its supposed efficacy in curing ruptures). *Polygonum minus, millegrana major, herniaria glabra* Lin. Sp. Pl. 317, is a small spreading plant, found in sandy ground; flowers in June and July; supposed to be diuretic and astringent.

HE'RPES, vel E'RPES, (from *ἑρπαι, to spread or creep*, from their quickly spreading). TETTER. Dr. Cullen places this disease in the class *locales*, and order *dialyses*; and defines it, phlyctenæ, or a great number of small ulcers crowding together, creeping and difficult to heal.

These ulcers in the skin are sometimes divided into five species. The *simple*, which consists of single sharp-pointed pustules of a yellowish white colour, inflamed about their bases, and naturally dry. They burn, itch, and smart a day or two, and then disappear.

The *tetter, ring worm, or serpigo; darta*; are the same in appearance, except that they accumulate in little masses; they are more permanent, for they contain more corrosive matter; they smart and itch more violently, penetrate the skin, and spread considerably, without forming matter, or coming to digestion. The cure is frequently difficult; and they sometimes return at certain seasons. If the disease is constitutional, slight mercurials are necessary; and a solution of hydrargyrus muriatus in lime water, in the proportion of sixteen grains to a pint, may be used as a lotion, or the white calx of mercury, combined with common ointment, may be rubbed on the part. About two scruples may be added to an ounce. When serpigo is constitutional or scorbutic, the great water dock root may be employed, either with or without the mercury, in the form of a diætic decoction.

Shingles, or zona aurca, herpes zoster, synonymous in Dr. Cullen's system with his erysipelas phlyctænodes, as sometimes accompanied with inflammation and fever. It appears in large clusters, on the neck, breast, loins, hips, or thighs: the heads are white and watery, and succeeded by a small round scab resembling a millet seed,

and called from thence *herpes miliaris*. In general the treatment is the same as in erysipelas: the chief indication is to take off the irritability of the system; and for this purpose the cortex Peruvianus and camphor are the best remedies. The prognostic of death from its surrounding the body is false; the malignity of the disease alone affording the only ground of fear. There is a chronic kind peculiar to old people, troublesome from the itching it excites, and sometimes dangerous. The bark internally, and externally, the lime water, occasionally with a small proportion of the muriated mercury, often succeed.

These two kinds were called by the ancients *vermis repens*; *vermis mordicans*; *formica miliaris*. Wiseman calls them *ambulatoria*.

Herpes dephascens, noma, noli me tangere, ulcus dephascens, esthiomenus, formix; and by Celsus *ignis sacer*, because, like the ulcerated erysipelas, it penetrates to the flesh, raising the skin, chiefly on the scalp, into scales of different thicknesses, and leaving a hard swelling on the part. Dr. Cullen thinks it an erythematous inflammation. It resembles an ulcerous erysipelas of a most corrosive kind. The hydrargyrus muriatus, as directed in the lues venerea, with a decoction of the woods, or sarsa, is useful in this complaint; and the sores may be washed with a solution of hydrargyrus muriatus in aq. calcis.

A dose of jalap every fourth day, with an electuary containing two parts of the bark to one of sassafras, has been successful. The mineral acids are sometimes very advantageous; and in this species the tincture of cantharides, recommended by Dr. Mead, we have found useful.

Mr. Bell, in his Treatise on Ulcers, places the tinea and the herpes, as varieties of that species of ulcer, which he denominates cutaneous; adding that the cutaneous ulcer, in all its varieties, may be included in the herpes farinosus, or dry tetter; herpes pustulosus, including the crusta lactea; the tinea capitis (see *ACHOR*); herpes miliaris; formica miliaris, cenchrius, of which the ring worm is a variety; and the herpes exedens, including the ulcers called depascent and phagedenic.

The *herpes farinosus* is the most simple kind. It appears on any part of the body, most frequently on the face, neck, arms, or wrists; comes out in broad spots, consisting of very small red pimples, attended with a troublesome itching, which soon fall off in the form of a white powder resembling fine bran: they leave the skin perfectly sound, but the pustules return in the form of a red efflorescence, fall off, and are covered with bran as before.

The *herpes pustulosus* occurs most frequently in children, generally in the face, and behind the ears; often on other parts of the head, but rarely on the body. It appears in the form of pustules, which are originally separate and distinct, but afterwards run together. At first they seem to contain nothing but a thin watery serum, which afterwards turns yellow, and, exuding over the whole surface of the part affected, at last dries into a thick crust or scab: when this falls off, the skin below frequently appears entire, with only a slight degree of redness on its surface; but when the matter is more acrid, on the scab falling off, the skin is found slightly excoriated. See *ACHORES*.

The *herpes miliaris* generally appears in clusters, though sometimes in distinct circles of very minute pimples. These are at first perfectly separate, and contain only a clear lymph, which, in the course of the disease, is excreted upon the surface, and forms small distinct scales, that fall off, and leave a considerable inflammation. From hence fresh matter exudes, with the same consequences. The itching in this ulcer is always troublesome, and the matter discharged so tough and viscid, that whatever is applied to the part adheres so as to be removed with difficulty. The whole body is subject to this disorder, but it most frequently appears on the breast, perinæum, scrotum, and loins.

The *herpes exedens* discovers itself on any part of the body, but mostly about the loins, where it sometimes spreads to such a degree as to encircle the waist. At first several small ulcerations appear collected into larger spots of different sizes and various figures, with always more or less of an erysipelatous inflammation. These ulcerations discharge a thin, sharp, serous matter, which sometimes forms into small crusts, that soon fall off; but the discharge is often so thin and acrid, as to spread, and produce similar sores around. Though these excoriations, or ulcers, do not in general proceed further than the true skin, yet the cellular membrane, and, on some occasions, the muscles themselves, are destroyed.

Dr. George Fordyce describes a variety of this disease under the name of *herpes rapiens*; and adds that it arises upon the head in small ulcers, covered with a brown, moist, shining crust, similar to venereal ulcers. It is cured, he observes, by the same methods which remove venereal ulcers.

In these cuticular diseases the fluids have been supposed vitiated, and repellents generally unsafe. This is certainly in a great measure true; and in young persons, as well as in robust habits, topical remedies must be employed with caution. In such cases the neutral salts are generally useful; and mercurials, antimonials, or both combined, are necessary at night, assisted in their operation on the skin by opium. In the more debilitated habits, bark with the warmer diaphoretics, particularly the mezereon, are proper, with the mineral acids, and a more generous diet. In all cases, bathing in the warm bath, and the utmost cleanliness in every respect, will be salutary.

In the weak habits, and in old persons, external remedies are most effectual. Simple lime water will be often useful; and about ten grains of hydrargyrus muriatus to a pint of distilled water, with a small proportion of muriated ammonia, is often a beneficial external remedy. In all cases, saturnine applications are either useless or injurious. Mercury must be sometimes continued with the warmer diaphoretic alteratives for a long time; and this has given credit to Spilsbury's drops, which are only a solution of muriated mercury. When the disease recurs, which is not uncommon, a milk and vegetable diet, with issues, and frequent doses of neutral salts, are the best prophylactics. If the disease has produced a deep foul ulcer, the preparations of zinc are the most useful applications.

See Tulpius, lib. iii. Marc. Aurel. Severinus, lib. iv. de Abscessibus, cap. 9. Turner's Diseases of the Skin. Bell on Ulcers, article Cutaneous Ulcer, edit. iii. p. 345. White's Surgery, p. 26.

HERPES. See PURPURA SCORBOTICA.

HE'RPES FACIE'I. In some constitutions, especially in females, the face is particularly liable to a species of herpes, peculiarly distressing to practitioners. Mercurials, with decoctions of sarsa and mezereon, sometimes succeed; occasionally the Dover's powder, with a small proportion of muriated mercury. Frequently all fail; but the following composition has sometimes been effectual. R. Sulphuris præcipitati ℥ ij. cerussæ acetatæ ʒ i. aq. rosarum ℥ viij. m. nocte maneq. utendum, phiala prius agitata. See Bell on Ulcers, p. 373.

HE'RPES FE'RUS. See ERYSIPELAS.

HE'RPES SERPIGO. The RING WORM; a cutaneous affection common in India, in which the eruption is circular, with a cavity in the middle, apparently surrounded by a ring. The remedy is the cassunda vinegar. An ounce of the fresh bark, roots, tops, or flowers, of the cassunda (*cassia sophera* Lin. Sp. Pl. 542) are boiled in a pint of vinegar to eight ounces, and a drachm or two applied two or three times a day, previously cleaning the part with soap and water. When this does not succeed, a mild mercurial course, interposing purgatives, with a milk and vegetable diet, has removed the disease.

HERPE'TON, (from ἔρπω, to creep,) a creeping pustule or ulcer. Hippocrates.

HERRING. A species of *clupea*, a rich, oily, and sufficiently wholesome food in strong stomachs. When dried in the smoke, they are very indigestible. The regular migration of herrings has been lately doubted, and their successive appearance on different shores accounted for from their coming to the shallower water for the purpose of depositing their spawn.

HE'RVÁ DE A'NIL LUSITA'NIS. See INDICUM.

HE'SPERIS, (from ἑσπερα, the evening, so named because it smells most in the evening). *Hesperis matronalis* Lin. Sp. Pl. 927. It is said to be diaphoretic and antiseptic; but is unknown in modern practice.

HE'SPERIS A'LLIUM. See ALLIARIA.

HETEROGE'NEUS, (from ἕτερον, alterum, and γενεῶν, kind). See ANOMOMERES.

HETERORRY'THMUS, (from ἕτερος, another, and ῥυθμός, number). See ARYTHMUS.

HE'TICH I'NDIS, AMERICANUM, vel ÆTHIOPICUM. A species of turnip in America, with leaves like those of briony: the root is as thick as two fists, and a foot and a half long. It is agreeable food, and aperitive.

HEUD, or HEUDE'EN, (*heud*, Arabic). See AGALLOCHUM.

HEXAGY'NIA, (from ἕξ, six, and γυνή, a woman). A class of plants, so named because they have six pistils, or female organs.

HEXA'NDRIA, (from ἕξ, sex, and ἀνδρ, vir). The name of the sixth class of Linnæus's system, comprehending those plants which have hermaphrodite flowers, with six equal stamens.

HE'XIS, ἕξις, (from ἔχω, to have). A HABIT. It is a permanent habit, in opposition to diathesis, or a transient disposition, which may more easily be removed. See CONSUETUDO.

HIBE'RNICUS LA'PIS, (from Hibernia, Ireland).

IRISH SLATE, *tegula Gallis, ardesia Hibernica; lapis fissilis Hibernicus; argille schistense tabulaire* Haüy, iv. 447; *argillite* of Kirwan; is a kind of slate, or soft

stone, found in Ireland and other countries, of a bluish black colour, staining the hands. When powdered it is whitish at first, but soon grows blacker; yielding in the fire sulphureous fumes, and acquiring a pale red colour. It is an argillaceous earth, with flint, lime, magnesia, and iron in a very small proportion. It is supposed to be an astringent, and was formerly given in hæmorrhages, and to prevent the bad effects of bruises. It is now totally neglected. See Lewis's *Materia Medica*. Neumann's *Chemical Works*.

HIBI'SCUS, (from ἵβις, a stork; said to chew and inject it as a clyster). See ALTHÆA and KETMIA.

HIBI'SCUS ABELMO'SCHUS. See ABELMOSCHUS.

HIDRO'A, (from ἵδρωσ, sweat,) pustules appearing in some constitutions, from sweating. It is the symptomatic kind of miliary fever called BOA, q. v. See DESUDATIO and PHLYCTIS.

HIDROCRI'TICA, (from ἵδρωσ, sweat, and κρίνω, to judge). Signs taken from sweat.

HIDRONO'SOS, or HIDROPYRE'TOS, (from ἵδρωσ, sweat, and νόσος, morbus, or πυρετός, fever). See SUDOR ANGLIUS.

HIDRO'TES CENCHROI'DES. See CENCHROS.

HIDRO'TICA, and HIDROTO'PSEA, (from ἵδρωσ, sweat). See SUDORIFICA.

HIDRUS. See ÆRIS FLOS.

HI'ERA DIACOLOCY'NTHIDOS. An electuary formerly prepared under this name, which hath long been neglected.

HIERANO'SOS, (from ἱερός, holy, and νόσος, a disease,) supposed to be the disorder which our Saviour cured in those who were said to be possessed of devils. (See CONVULSIO.) A continued kind of convulsion, without pain or loss of sensibility.

HI'ERA PI'CRA, (*ἱερος πικρός*). HOLY BITTER; now called *fulvis aloeticus*; formerly *hiera logadii*, and made in the form of an electuary, with honey: the species are now kept in dry powder, prepared by mixing socotorine aloes, one pound, with three ounces of white canella.

HIERABO'TANE, (from ἱερος, holy, and βότανη, an herb). HOLY HERB. A species of verbena. Dioscorides. See VERBENA.

HIERA'CIIUM, (from *hierax*, a hawk). *Hieraculum*, HAWKWEED. See ACCIPITRINA.

HIERA'CIIUM LO'NGIUS RADICA'TUM. LONG ROOTED HAWKWEED. *Hypochaeris radicata* Lin. Sp. Pl. 1140. The stalks of each species are full of branches, slender and elegant; the leaves disposed alternately; the calyx thick, firm, and expanded; the seeds smooth and angular, or striated.

The root of this species strikes deep into the ground; is long, thick, and but little branched; the leaves lie flat on the ground, are rough and hairy; the flowers like those of the dandelion, but less yellow and downy; the seeds long and slender. It grows in fields and meadows, and flowers from May to September. It is supposed to be cooling, aperient, and diuretic.

HIERA'CIIUM ALPI'NUM, *pannonica, costa herba, costa pulmonaria, pilosella major, dens leonis, pulmonaria lutea*. BROAD LEAVED HUNGARIAN HAWK WEED. *Hypochaeris maculata* Lin. Sp. Pl. 1140. It grows on chalky hills, flowers in June, and is extolled in pulmonary disorders.

HIERA'CUM MINUS, *hieracium leporinum*, LESSER HAWKWEED; *hyoseris minima* Lin. Sp. Pl. 1138; grows in pasture ground, flowers in June and July: its virtues the same as those of the *hieracium majus*, but supposed to be more considerable.

HIERA'CUM MAJUS, also called *sonchus repens*. GREATER HAWKWEED; *sonchus arvensis* Lin. Sp. Pl. 1116; is found in fields; flowers in July; the leaves are cool, and moderately astringent. See Raii Hist.

HIERA'CUM MONTANUM, et **PULCHRUM**. See **CHONDRILLA**.

HIERA'CUM PILOSELLA, Lin. Sp. Pl. 1125; is bitter and astringent, used internally in diarrhœa, and externally in itch and herpes.

HIERA'CULUM. See **HIERACIUM**.

HIERA'TICUM, (from *ἱερός*, *sacer*). The name of a malagma, formerly appropriated to disorders of the abdominal viscera; named from its divine virtues.

HIERO'PYR, (from *ἱερός*, *sacer*, and *πῦρ*, *fire*). An erythematous inflammation.

HIGHMORIANUM ANTRUM. See **ANTRUM GENÆ**.

HIGUE'RO. The **CALABASH TREE**; *crepentina cujete* Lin. Sp. Pl. 872; is a large tree common in America, and the American islands; but one species was known to Linnæus, of which he has noticed three varieties; but later authors form three species, viz. the *crepentina cujete*; the *c. cucurbitina*; the variety α of Linnæus, and the *cujete* with hard fruit, var. γ . The plant belongs to the solanaceæ. The first is a small tree with a twisted trunk, extending horizontally on every side, and furnished at each knot with oblong, undivided leaves collected in bundles. The flowers resemble those of a lily, are of a white and greenish colour, but a disagreeable smell. The fruit of various sizes and figures, is green at first, but when ripe it is black and hard, containing seeds like a gourd, and a yellow kernel. The unripe fruit contains a white juicy pulp, smelling like nasturtium, but of a sweetish taste; and is preserved with sugar, and used in fevers. The ripe affords a shell for cups, &c. The pulp of the ripe fruit is employed in dropsies and diarrhœas; as a remedy for burns and diseases of the head. In the French islands it is employed in diseases of the breast, and in contusions after violent falls. The other species are not remarkable for any peculiar medicinal powers. See Raii Historia.

HIMANTO'SIS, (from *μας*, *a thong of leather*). Relaxation, or lengthening, and smallness of the uvula, when it hangs down like a thong.

HIMAS. Properly a leather thong, or strap; but in medicine it is a laxness of the uvula, when it becomes long and slender, called also *cion*. It differs from the *clonis*, which is a thickened uvula.

HIN, **HINDISCH**, and **HING**, Indian and Persian names of **ASAFÆTIDA**, q. v.

HINAWARU. See **INDICUM**.

HINKA. See **CARYOPHILLUS AROMATICUS**.

HIPPACE, (from *ἵππος*, *equus*, *a horse or mare*). The rennet of a colt; and cheese made of mares' milk.

HIPPOCASTANUM, or **HIPPOCASTANUM**, (from *ἵππος*, *equus*, and *καστανόν*, *a chestnut*; from its size). The **HORSE CHESTNUT TREE**, *castanea equina*, *havina*, *æsculus hippocastanum* Lin. Sp. Pl. 488; natural order *trihilatæ*. This tree frequently grows to a great

height, and from the upper part of the trunk usually sends off numerous spreading branches, covered with a rough brown bark; the wood is white and soft, but soon decays, and is of little value. The fruit in appearance resembles the Spanish chesnut, and is eaten by sheep, goats, deer, oxen, and horses; the latter are fond of it, and it is said to cure their coughs and pulmonary disorders. Starch has been made from it; and could its bitterness and acrimony be separated, it has been supposed that it would make a wholesome bread. It has been recommended as a sternutatory in powder, or by drawing the steams of a decoction up the nostrils, and has consequently been employed to produce a discharge from the nose in ophthalmy, head ach, &c. On the continent the bark is held in great estimation as a febrifuge, and considered to be a medicine of considerable efficacy. Jo. Jac. Zannichelli affirms, that, after many trials, he has found the bark of these trees to have the same effect as the Peruvian bark. By some practitioners it has been substituted for the latter, and said to be attended with equal if not superior advantages. For medical purposes it is to be taken from those branches which are neither old nor young, and exhibited as the Peruvian bark. Buchholtz prefers dissolving a drachm of the extract in an ounce of cinnamon water, giving sixty drops of the solution every three hours. It rarely disagrees with the stomach, but its astringent effects generally require the administration of laxatives. See Raii Historia Plantarum. Woodville's Medical Botany.

In England we have the white, yellow, and scarlet flowering chesnut trees, which are cultivated in gardens and walks, and flower in May and June.

HIPPOCRAS. See **CLARETUM**.

HIPPOGLOSSUM, (from *ἵππος*, *a horse*, and *γλωσσά*, *a tongue*; from the resemblance of the leaf to a horse's tongue). See **LAURUS ALEXANDRINA**.

HIPPOLAPATHUM, (from *ἵππος*, *equus*, and *λαπάθιον*, *a dock*). See **LAPATHUM HORTENSE**.

HIPPOLAPATHUM, **ROTUNDIFOLIUM**. See **LAPATHUM ALPINUM**.

HIPPOLITHUS, (from *ἵππος*, *a horse*, and *λίθος*, *a stone*). A calculus found in the stomach or intestines of a horse. See **CALCULUS**.

HIPPOMANES, (from *ἵππος*, *a horse*, and *μανομαι*, *to be mad*;) a name of the *cynocrambe*, *apocynum*, or *cynomoron*, because, when eaten, it seems to produce madness in horses. It sometimes means the juice of tithymalus, and occasionally the secundines of a mare, or the fleshy substance which adheres to the forehead of a foal.

HIPPOMARATHUM, (from *ἵππος*, *a horse*, and *μαραθρον*, *fennel*). **HORSE FENNEL**; and **ENGLISH SAXIFRAGE**. See Raii Hist. Plant. **SAXIFRAGA ANGLICA**.

HIPPONE. The name of a malagma described by Ætius.

HIPPOPHÆS, **HIPPOPHÆSTUM**, (from its juice purging horses). Dioscorides describes it in lib. iv. cap. 162; but it is not known to modern systematics. The synonyms, according to Dale, are the *cnapnos rhamnus*, *lappago*, *hippomanes*; and it is probably the *hipphophae rhamnoides* Lin. Sp. Pl. 1452; the *rhamnus salicis folio angustiore fructu flavescens* of C. Bauhinc. The **PURGING THORN**. It grows in the Morea, and the juice is an active purgative. Though the *rhamnus*

catharticus and the tithymalus maritimus vel spinosus have also been considered as synonyms, they seem to have different properties specified under their separate titles.

HIPPOSELI'NUM, (from ἵππος, a horse, and σελιον, purslane; so named because it resembles a large kind of purslane). **ALEXANDERS**; *Smyrniun, mace-rona, herba Alexandrina, grielum, agrioselinum, Smyr-nium olusatrum* Lin. Sp. Pl. 376; an umbelliferous plant, with leaves like smallage, but larger. It is a large kind of parsley, and was formerly blanched in gardens for culinary use. The seeds, macedonensium semina, are bitterish, aromatic, and carminative, yielding their virtue to rectified spirit of wine, but not fully to water. The roots are bitter, and recommended as resolvent, diuretic, and emmenagogue. On incision they yield a whitish juice, resembling myrrh; whence the plant hath been called, from one of the names of that gummy resin, *Smyrniun*. See Raii Historia Plantarum.

HIPPUS, (from ἵππος, equus, a horse). A trem-bling and twinkling of the eyes, supposed to be usual with those who ride on horseback. Gorræus thinks it is an affection contracted from the birth, owing to a convulsion in the muscle which sustains the eye.

HIRA, (from hir, the palm of the hand; because it is usually found empty,) sometimes supposed to mean the jejunum; at others extended to all the intestines, or even all the contents of the abdomen.

HIRAPITA'NGA. BRASILIE'NSIBUS. See **BRASILIENSIVM LIGNUM.**

HIRCUS BEZOA'RTICUS, (quasi *hirtus*, from his shaggy hair). The goat which affords the oriental bezoar. See **BEZOAR ORIENTALIS.**

HIRQUUS, (from ἵκος, a hedge). The great angle of the eye.

HIRSU'TIES, (from *hirsutus*, hairy). Unnatural hairiness of the body.

HIRUDO, (quasi *haurudo*, from *haurio*, to draw out): The **LEECH**; *sanguisuga, exos*; first noticed by Themison. Those whose backs are striped, and bellies spotted, which are taken from clear running waters over a sandy bed, are preferable.

The hirudo is a genus of aquatic vermes, characterised by an oblong body, very contractile; having each extremity capable of being expanded into a fleshy disc, by which they adhere to the body, with a kind of suction similar to that of a cupping glass; a triangular mouth situated under the anterior extremity.

The body of a leech is composed of numerous rings, or rather circular muscles, by which the particular motions of the animal are performed. Their skin is unequal and tuberculous in different degrees, in the different species, but always feels smooth to the touch, because it is covered by a slimy fluid, designed to facilitate its motions. Their head, in a state of contraction, is more pointed than the opposite end: but each extremity is equally enlarged when they fix. The mouth of the leech is a triangular aperture, placed at the bottom of what may be styled the anterior cupping glass, armed with three very sharp, strong teeth, which can pierce even the skins of horses and oxen. It is an instrument with three cutting edges, each of which is furnished with sixty little teeth. At the bottom of the mouth is a nipple of a firm fleshy consistence, which sucks the blood that exudes from the triangular wound

by exhausting the air. In this operation the nipple fixes on the skin, and when drawn back a vacuum ensues. After the wound is made, the action is apparently repeated, and the power is so considerable as to fill the vessels around; a circumstance from which both advantages and inconveniences arise.

We next find the larynx, whose strong fibres contract the diameter of the canal, and carry the blood, which has been drawn, into the stomach. This viscus consists of a series of membranous sacs, furnished with valves, which can retain the blood for many months without coagulating. In a leech of a moderate size there are about twenty-four of these sacs. As the blood which they draw contains no heterogeneous particles, they require no aperture to carry off the excrementitious parts, and have consequently, it is said, no anus. M. Morand, from whose Memoir on Leeches much of this description is drawn, thinks that the slimy moisture on the surface, which is thrown off in blackish filaments, found in the water they inhabit, may form the whole of the excrementitious fluids of the constitution.

On each side, under the belly of the leech, are two longitudinal vessels which divide into branches; contract and dilate; carrying a grey fluid. In the middle is a nervous cord, composed of twenty-three ganglia; and on each side glands filled with a clear liquor. These glands have several vessels, which are lost in the body of the animal. So distant from the truth are those physiologists who deny that the Galvanic power acts on the nerves, because leeches are affected by it, supposed to have no nerves.

Leeches seem to breathe by the mouth, but have no organs which correspond to lungs. Insects which breathe by lateral spiracula are killed when covered with oil. When the leech is put into oil, it lives many days, and a slough separates from it, so tenacious, when taken out, as to retain the form of the body. The greater number of leeches have eyes, and some species have so many as eight; but in others no such organ has been observed. These animals swim, like eels, by a vermicular motion; but this is more generally in a longitudinal than in a lateral direction. When they walk they fix the fore part of the body by the mouth, and then draw the back part. They then fix the latter, and extend the former.

When the greater number of the species of hirudo are cut transversely, the two parts do not immediately die, for the head lives considerably longer than the tail. If the section is not complete, the animal raises the wounded part above the water, and keeps it in the air, till each end is cicatrised, for the parts never unite; and the fluids, usually carried downwards, are discharged in abundance from the wounded part. The operation greatly weakens them, and they soon become a prey to those with whom they are placed, after the cure has been completed.

Leeches are hermaphrodites, and generally viviparous. The organs of generation, according to Redi, resemble those of a snail. The penis lies under the œsophagus, and the aperture of the vagina immediately below it. Their young are born in the earliest part of the spring. As the animals are semitransparent, the young are seen in the body of the mother, in the form of round seeds, and seventy have been counted in a single leech. In

their progressive state they seem to grow not only by evolution but by augmentation, as the number of the rings seems to increase. They are found in fresh and salt water. The former prefer lakes or ponds where a great quantity of vegetables grow. They are common in every part of Europe; but less so in the southern regions. They appear to live for many years; but, independent of the danger of the lakes being dried, or the waters putrifying, they are devoured by fish, water fowl, by the larvæ of insects, and by the insects themselves. They also devour each other; and Vauquelin found that the hungry leeches bled without mercy those which were full. When in want of blood, they suck the larvæ of insects, worms, and other animals, which live or are found by accident in the water. They can live with little nourishment for many months, and pass the winter, often a great part of the summer, involved in the mud, when the lakes are dry, without eating.

Sea salt, tobacco, and every salt or acrid substance, kill these animals, and this is the method of disengaging them from the body; for if torn off, the head is left in the wound, and a troublesome suppuration ensues. If cut in two, the head continues the suction, while the blood is discharged from the wound, and all the consequences of an hæmorrhage follow.

The *hirudo medicinalis* Lin. is the species chiefly employed; and the *hirudo sanguisuga*, or black leech, is accounted poisonous. It seems, however, only to make a larger wound, and to suck with more violence. They must be collected in the spring, kept in pure water, which must be frequently renewed, in a place not too warm. It is advised that some clots of blood should be occasionally thrown into the water, while a certain proportion should be kept hungry, for immediate use. Some years since, leeches were supposed to be useful barometers, and it was said that they lay at the bottom of the vessel when the following day would be clear and warm; but that when rain would come on before the noon, they mounted to the surface, and continued there till the fine weather returned. When a storm of wind approached, they were said to run round their prison with considerable celerity, and to stop only when the wind began to blow. When a tempest approached, the leech was said to rise out of the water, and continue above it many days, appearing restless and agitated; that it remained at the bottom of the bottle, contracted to a round ball, during a frost; and during snow and rain it fixed itself to the stopper of the bottle, remaining at rest. These phenomena may be correctly stated, and a single leech may appear to feel the variations of the atmosphere; but whoever has observed many of these animals in a glass vessel, will have perceived that, in any circumstances, they have appeared sometimes still, occasionally restless, some at the bottom, others at the top, of the vessel, some unquiet, others at rest. They are certainly very susceptible of the effects of lightning, and often killed by it. A small species was found in Egypt, not larger than a hair when not gorged with blood. They often fixed in the throat of the soldiers, and were only removed by forceps. In medicine we employ only the two following:

1. *Hirudo medicinalis*, long, blackish, with lines of different colours, spotted with yellow below, and without eyes. 2. *Hirudo sanguisuga*, the horse leech, long,

black, of a greyish green colour below. About fourteen or fifteen species are known, one of which is described in the first volume of the Linnæan Transactions, p. 188, and said to breathe by gills; but should the latter be true, the animal must be referred to another genus. The author, however, Mr. Menzies, is not explicit on this part of his subject: the setæ he describes may not be, or may not lead to, gills. Another leech is described in the same volume by Dr. Shaw, p. 93, *hirudo viridis*. It is oviparous, and, like some other species, is reproduced by cutting.

We have enlarged more fully on this subject because we have no accurate description of this useful animal in our own language. We must now return to what is more strictly our object, their medical use.

Leeches have lately become a fashionable remedy in every topical inflammation, in topical pains, and in the greater number of tumours, internal bruises, and obstructions. In scirrhi and incipient cancers they are highly commended; in the white swelling of the knee, in swellings of the periosteum, in the inflammatory state of buboes, they are supposed to be highly useful. In fact, they have been so much employed that our ponds and lakes have been, in a great measure, depopulated; and in many parts of the kingdom they are with difficulty procured. The mode of their operation must be afterwards considered, but the principles are sufficiently explained under the article of BLISTERS, q. v. The peculiar advantages which result from their use seem to be owing to their exhaustion. They fill the vessels around, and not only relieve from the quantity of blood which they draw, but from that which they accumulate in the subcutaneous vessels. By this effect they are often singularly useful; but from the same circumstance, the bleeding, if a bone be not subjacent, is with great difficulty stopped. Equal advantages may be often obtained by cupping with scarifications, without the same disadvantages; and this operation should, in many instances, be preferred.

The leech, when full of blood, drops off; but should it not do so in time, a little salt will always induce it to quit its hold. Salt has been thrown on the animal to make it disgorge the blood which it has sucked, but the leech is generally killed in the experiment. A more easy way to discharge the blood, and save the animal, is to hold it in the hand, and gently squeeze it in a napkin from the head downward. The blood flows copiously from what may appear the anus, or through the ruptured extremity of the intestinal canal, and the worm is not essentially injured.

Leeches must be kept hungry, and the part to which they are to be applied must be wetted with warm milk, blood, or syrup. If a sufficient quantity of blood is not drawn, cloths wrung out of warm water must be applied on the orifice, or the part may be put into warm water: in either way the bleeding may be prolonged.

Leeches are sometimes applied to the anus when the hæmorrhoids are suppressed, and to the gums in inflammations from teething. In each case they may escape into the intestine or the throat; but an injection of salt, dissolved in the infusion of tobacco, will destroy them in the former instance, and gargles or draughts of salt water in the latter. In general a healthy leech will suck about an ounce of blood; but warm cloths

will continue the evacuation for some time after the animal is satiated.

The curious may consult the following writers on leeches, viz. Aldrovandrus, Gesner, Swammerdam, Redi, and Stahl. Among the moderns, the Memoirs of Morand, Bosc, and Vauquelin.

HIRUNDINA'RIA, (from *hirundo*, a swallow; so called from the resemblance of its pods to a swallow). SWALLOW WORT. See **ASCLEPIAS**.

HISPA'NICUM VIRIDE. See **ÆRUGO ÆRIS**.

HISPI'DITAS, from *hispidus*, rough, hairy). Hairiness in general; but sometimes limited to the diseases called *phalangosis*, or *distichiasis*.

HISPI'DULA, (from the rough woolly surface of its stalks). See **GNAPHALIUM MONTANUM**.

HISTO'RIA, (from *ἱστορία*, a case). An HISTORY. In medicine it is a medical case, or in the French idiom an observation.

HOACHE. A Chinese earth resembling, it is supposed, steatite, or soap rock, but fusible, and more probably argillaceous, with a mixture of silex.

HOA'XACAN. See **GUAIAACUM**.

HOCIA'MSANUM. See **AGRIMONIA**.

HOITZILO'XITL. See **BALSAMUM PERUVIANUM**.

HO'LCIMOS, (from *ἔλω*, to draw). An epithet applied to what may be drawn out, and still preserve its continuity. It sometimes means a tumour of the liver. See Galen de Loc. Affect.

HO'LCUS, (from the same). See **MILIUM INDICUM**.

HOLI'PPÆ. Thin cakes made with flower and sugar, poured upon a hot iron, figured, and then set on the fire. The name is now appropriated to sweetmeats; occasionally to such as are laxative.

HO'LLI. The Indian name for what the Spaniards call *alli*, a resinous liquor, distilling from the tree called *chilli*; used in dysenteries. See Raii Historia.

HOLO'CYRON. See **CHAMÆPITYS**.

HOLOPHLY'CTIDES, (from *ὅλος*, whole, and *φλυκτῆς*, a pustule). See **PHLYCTENÆ**.

HOLOSCHÆ'NOS, (from *ὅλος*, whole, and *σχῆνος*, a bulrush). See **JUNCUS ODORATUS**.

HOLO'STES, **HOLO'STEUM**, (from *ὅλος*, whole, and *ὀστέον*, a bone; from their use in restoring broken bones). See **OSTEOCOLLA**.

HOLOTHU'RION, according to Bontius, a poisonous substance; but its nature is unknown.

HOLOTO'NICOS, (from *ὅλος*, whole, and *τείνω*, to stretch). An universal convulsion, or rigor of the whole body. See **TETANUS**.

HOLQUAHU'ITL. See **CORTEX PERUVIANUS**.

HOLYWELL WATER. A simple cold water, remarkable for its purity, similar to Malvern.

HO'MA. An anasarous swelling.

HOMO. **MAN**. In a work, the object of which is to detail every thing which relates to the human body in health, or disease, an article under this title will perhaps not be expected. No such occurred to our predecessors; and had we found appropriate places for many of the subjects which will now claim our attention, we should not have introduced the subject in this connected and comprehensive view in one article; where, as already remarked, we purpose to collect all those circumstances relative to his structure and consti-

tution, both mental and corporeal, which cannot, with advantage, be displayed in distinct, independent disquisitions.

Man stands supereminent among created beings, the first of the Almighty's works, the link probably between other animals and beings of a diviner nature. Man alone looks towards heaven: he only, by the excellence of his mental powers, can guard against the accidents to which his imbecility and the inferiority of his senses would subject him: he only can correct by his own reason the moral imperfections implanted in his nature. Gloomy philosophers delight to magnify his inferiority in many respects to the animals around, to sink him even below the monkey, which he appears, at first sight, to resemble in form; and Linnæus has given a sanction to their misrepresentations by his arbitrary classification of man with the ape; and, what more strictly shows the weakness of his system, with the bat. The Swedish naturalist had once determined to class animals, like plants, from the organs of generation. In this respect the distinction would have been very striking, for a most complicated apparatus is required to build up the first of nature's works. Had Linnæus followed this plan, he would have found the ape truly a beast, from the deficiency of the scrotum, the bone of the penis, and the want of the vesiculæ seminales. In the female, the cornua uteri, which are found in every species of ape, except the pithecus; the length and direction of the vagina would have been very striking marks of distinction, which the teeth scarcely furnish. Various other discriminating appearances will soon occur.

The FORM OF MAN is perhaps alone sufficient to distinguish him from other animals; and in the comparative view we now propose to take, we shall chiefly attend to the peculiarities of structure connected with form. The position of the head establishes the station of each animal. In man it is short and rounded; nearly balanced on the atlas, it scarcely falls on either side. In the Negro, the weight inclines forward, and the loins are thrown back to retain the equilibrium. In the ape the occipital hole is still farther back, and the balance only preserved by a still more oblique position. The other animals rest on the ground in an horizontal posture, and the weight of the head is supported by what is styled the cervical ligament. This is not found in man, as he wants not its assistance. It has been said, that men, found wild, have walked on their hands and feet. This is not probable, for the wild girl of Champagne, the Hanoverian wild boy, the two wild men of the Pyrenees, and the savage of Aveyron, walked upright; and we shall find that the structure of the muscles of the feet is not adapted for walking both on them and the hands: in this position also the eyes would be turned downward, and man could neither avoid danger nor discover his food.

The size of the head equally distinguishes man from animals. Almost universally the brain of man is larger, in proportion to his bulk, than that of any other animal. If there are some exceptions, the medullary part seems designed to compose the very large nerves sent to the muscular organs, in which the whole appears exhausted. These in man are comparatively small, so

that the brain has evidently some other use, besides affording the source of activity to the muscles; an use denied to animals. We consequently find, that wherever the brain is large, and the nerves proportionally small, the intellectual powers are considerable, the strength of the body comparatively little, and the contrary. In the Negro the nerves are larger in proportion to the mass of the brain than in the white man; and his skull is less, though his face is more extensive. One method of determining the size of the face is that of Camper, formerly mentioned, viz. drawing the line from the chin to the forehead, which forms, with an horizontal line, a larger angle in an European than in a Negro and an ape, successively. Another method is to place the head in its natural position on the atlas, and to measure the angle, formed by a line drawn from the chin to the foramen occipitale, with one which passes through the vertebral column. The more obtuse this angle is the more contracted is the skull, and the more distant the foramen. The distance between the chin and the chest is of course greater in the Negro than the European; proportionally more distant successively in the dog, the hare, the sheep, the horse, the hog, and the whale, where the face is parallel to the vertebral column. On the contrary, the more the animal reflects, the more the face is sunk and the front advanced. "A Negro to look forward raises his head above his breast: an ape still more: philosophers depress the chin; and the Jupiter of the ancients, with his eyes bent, seriously looking downwards, has the chin depressed on his breast."

The clavicle is a bone of which many animals are deprived, and varies in its form and its length. The more the chest is contracted, the shorter is the clavicle, if it at all exist. The organs of deglutition are influenced by the diet.

In the larynx of apes we find a sac, into which the air passes when breathed, so that it can neither affect, with the necessary vibrations, the ligaments of this organ, nor be influenced by the aperture of the glottis. We cannot expect, therefore, in these animals any articulation, but only a sharp indistinct noise, expressive by its acuteness of anger, or by its graver tones of satisfaction.

The more distant the animal is from man, the more deep are the indentations of the viscera to yield to the more rapid movements. The heart is situated almost transversely in the human diaphragm, but inclines in the apes, approaches the sternum in the palmated animals; in the hoofed and the cloven-footed animals it is suspended almost vertically on this bone; and from the man to the horse its position varies nearly a quarter of a circle. The size and bulk of the nipples are proportioned to the extent of the horns of the uterus, since each is connected with the number of the young ones.

By means of these characters we can ascertain the discriminating forms of man, and determine what are common to him and the quadruped. He only is a biped. He only has two thumbs on his hands, without any on his feet, while quadrupeds have one only on each extremity, as the apes; on the two inferior extremities, as the sariga and the marmot; or are wholly deprived of them, as the greater number of quadrupeds. In man the body rests on the feet, and the talus makes a right angle with the leg. The apes, the makis, the

dogs, and even the elephant, walk neither on the ankle nor the talus, but on the toes. As we recede from man, the more the part on which the animal rests diminishes, and the talus becomes proportionally more acute. Many animals rest on the sciatic tuberosities, and on the bottom of their feet: they then raise the body, and employ the superior extremities like hands; but though several apes have an additional little bone in the carpus, they do not possess the dexterity of man, as the thumb is small, and not capable, as in the human body, of counteracting the power of the other fingers.

From the muscular structure of the extremities, it is obvious that the ape can only move many of the fingers at once; that it cannot bend the thumb without at the same time bending the other fingers. Of course it does not possess those motions in which the action of the thumb is combined only with that of the fore and middle finger, so useful in the arts. In fact, the hand of the ape is made only to hold. The inferior extremities, from their peculiar structure, are calculated for the same purpose.

In man, the flexor muscles of the leg terminate in slightly rounded projections towards the most elevated part of the tibia. In the ape these muscles extend far on the internal surface of the same part, where they form a cord, which prevents their perfect extension on the thigh. The flexor muscle in these animals, passing under the heel bone, is a decisive argument against the idea of their standing erect. In man the bone is naked, which shows that he was designed to rest on it, which is compatible only with an erect position.

In man the vertebræ form the column which supports the head, and fixes the different viscera in their situation. The cervical vertebræ, in all animals, are constantly seven. The dorsal vertebræ are the same in number as the ribs. The lumbar vertebræ, usually five, are more numerous in proportion as those of the sacrum diminish. Carnivorous animals have six, sometimes seven; the sloth four, and the elephant three. As we recede from the human race, the coccyx extends. In some animals the pieces even amount to thirty-two. The sternum in man is broad and extensive; in the greater number of animals narrow. Man alone has the bold projecting chest, which, increasing the resistance to the air, diminishes the rapidity of his motions. The number of its bones is proportional to that of the ribs. The latter varies. In the elephant they amount to forty; in the sloth to forty-six. The smallest number is twenty-two. The trichectus has but four true ribs.

The thigh bones and the pelvis of the human race are larger and flatter than those of other animals, which add to the solidity of the upright position, by giving a firmer hold to the muscles attached to it. The direction of the female vagina is nearly transverse from the sacrum to the pubes, while it is in the axis of the pelvis in quadrupeds. This allows the latter to produce their young with little pain or trouble; but if it had been the same in the human race, who walk erect, abortion would be frequent. Thus the female pays a heavy penalty for the distinction of the upright position.

Man differs from other animals in many respects, which do not influence very essentially the form. The teeth, though the same in number and form with those of some animals, are more closely set; nor, in the human jaw, are there any intermaxillary bones. We differ

also by the palpitating fontanelle at birth ; by our long and feeble infancy ; by the menstruation of the female, which renders conception equally easy in different seasons ; by the delicacy of our skin ; by wanting the suspensor muscle of the eye, the panniculus carnosus, the arterial net-work, the pancreas of Asellius, the corpus highmorianum, the hepato-cystic ducts, &c.

Man is defined a naked animal with two hands and two feet, who walks upright, is capable of reason, and susceptible of civilization. By his organization and structure he belongs to that class which has a double nervous and vertebral system, and ranks with animals whose blood is warm, whose heart is double, and who suckle their young at their breasts. Our peculiar advantages place us at the head of the animal kingdom. The complication of our organs multiplies in the same proportion as our functions, and equally extends our faculties.

It has been doubted whether *man, in his different forms and different situations, is of one species only*. Scripture informs us that one man was created ; but has not limited the creation to a single individual. Religion is not, therefore, affected by the discussion or the decision. We have seen the distinctions in form which separate man from the brute, and we have found that the Negro is a connecting link between both. The Negro has the narrow retreating fore head and hind head, the flat bone of the nose, the retreating chin, the occipital hole far beyond the centre of the cranium, the long and strong under jaw, large bony orbits, and a wide meatus auditorius, the long fore arm, small calves of the leg, long tendo achillis, with a manner of walking between the motion of the ape and the man. He, therefore, forms the link which unites man to brutes, while man may possibly connect animals with angels. Naturalists have distinguished different species of brutes from this circumstance, that they do not copulate, or that the offspring is not fertile. Yet more attentive observation has found that those hybrid productions will sometimes be productive ; but they are soon lost. By this test also the African Negro would scarcely appear of the same species with ourselves ; for were he so, it is calculated that the West-India islands would long since have been inhabited by mulattos, or people of colour. On the contrary, *their* children, if any, as Mr. Long remarks, are very few, and in the second generation they are childless. There seems to be little doubt, then, that there are two species of the human race, at least ; and when we examine the inhabitants of different regions, we find distinctions equally striking ; the copper-coloured American, for instance, appears in no less a degree to differ from the two others. It is in vain to argue that the Negro is black from the heat of the sun, for the Ethiopian, the Hindoo, and the Arab, are equally exposed to high temperatures ; or that the European is bleached in a colder climate, for this would not change his structure. M. Virey has proposed a division of the human race into those whose facial angle is from 85 to 90°, and those in whom the angle is from 75 to 85°. The first species comprehends the Arabs, the Gentoos, the Celts, and Circassians, who are white ; the Chinese, the Mongol-Kalmuck, and the Ostiack Laplander, who are sunburnt ; and the American and Charib, who are red. The second species comprehends the deep brown, the black, and the blackish ; containing the Malay, the

Caffre and Negro, the Hottentot and Papou respectively. The Europeans are, in this arrangement, styled *Celts* : he should rather have called them a Gothic race. The Hungarians, the Asiatic Russians, and the Laplanders, are included under the Mongols. We are not prepared to contend that these are different species. The three which we have pointed out seem to be so ; and the Gentoos, the Hottentot, and the Papou, have some claims to this distinction, which will be better ascertained when their forms have been more accurately examined.

Of the constitutions of the first species, the Europeans, we need not speak. The Negro is like the brute, whom he approaches in form, rapid in his movements, quick, violent, and savage in his passions and resentments, with little active energy or sensibility. He bears heat with ease, is not susceptible of the action of the remote causes of fever, but with little activity of constitution when diseased, soon yields and dies in situations where the European would be in little danger. The American is patient, steady, and persevering ; with great acuteness of perception, and a soundness of judgment ; but possessing little sensibility, and not very susceptible of civilization. The Hottentot and the Hindoo of the lowest cast, which we call the *gyftie*, if he be a Hindoo, approach most nearly the brute in their manners. Imitation is a striking trait in all the lower races of mankind, as well as in the ape. The frequent repetition of the action of particular muscles occasions a habit which renders the subsequent repetitions more easy, and the action more certain. We cannot consider the monkey without being astonished at the rapidity and the uninterrupted succession of his motions. "It seems as if an irresistible power eternally torments him : he is agitated ; he advances and retires ; he is eager to mount, and as hasty to descend. This restlessness is undoubtedly a great obstacle to his improvement. What can we teach him, who is always in motion, since there is no study without reflection, and to reflect he must stand still?" This elegant and judicious reflection of M. d'Azyr is applicable to other races besides monkeys.

If we were to be more minute, we might remark that the happy proportion of solids and fluids which composes the sanguine complexion of the Celt, or Goth, of Europe, and which becomes bilious among the Vandals and Slavonians, appears still stronger in the extensive ramifications of the Mongol tribe, as we find from the observations of Pallas and the learned Russian travellers. It takes, however, a nervous shade in the southern races. The Malays have constitutions still more irritable and nervous, which renders all the inhabitants of the torrid zone pusillanimous and melancholy. The temperament of the Charib, like the American, is concentrated in muscular energy, with little sensibility ; and the phlegmatic constitution of the Negro is still more striking in the Hottentot.

The different races of man differ in minuter parts of their form. The Hindoos, the Hottentots, the Peruvians, the Chinese, Esquimaux, the inhabitants of New Holland, and some others, have very small hands in proportion to the rest of the body. The Hindoos have very long legs and thighs : they are very short in the Mongol races ; large in the inhabitants of New Zealand ; deformed and bent in the Negro. The last deformity has been observed from the remotest ages, and was

noticed by Aristotle (Problems, No. 5—14). The ears are large and projecting in all savage nations; placed higher in the Hindoo than the European head, and sometimes moveable. The inhabitants of the east of Asia have the eyes placed diagonally. The general proportions of the head to the height are variable. The whole length of the Kalmuck is not equal to six times the head; while the elegant Grecians made their most beautiful statues, as the Pythian Apollo, and the Venus Pudica, equal to seven or eight. The Esquimaux and Samoïdes are only about five times the length of the head. All the barbarian races of the north have very large heads, thick and short necks, large and raised shoulders, a square shape, and a harsh outline. The dwarf has short stunted limbs, an enormous head, and a thick body; while the giant is thin and weak, with legs peculiarly slender. But to this point there are exceptions, to be afterwards noticed.

The colour of the different races has excited greatly the attention of naturalists. It has been attributed to heat; and numerous are the authors who have laboured to prove, that in a higher temperature we should have been all black, or, as already hinted, that we were once black, and become white only by effeminacy, or a degradation of our nature. This subject has furnished the credulous Volney (for even deists can be credulous when in opposition to religion) with a subject of declamation, that we now oppress the Negroes, to whom, as the reputed ancestors of the Egyptians, we owe all arts and sciences. Neither position is true. The ancient Egyptians were not Negroes, and our sciences and arts were derived from Asia. If we examine the human race, as scattered over different parts of the globe, with the discriminating accuracy of Zimmerman, we shall find that the Negro is not confined to the hottest regions; and we have shown that he is distinguished from the white more pointedly by structure, in which temperature has no concern, than by colour, which we know not that temperature can influence. Were farther evidence wanted, we might adduce that of Mungo Park, who found the brown Mahometan intermixed, in similar climates, with the black Negro. The copper coloured American is equally distant from both the Celt or Goth, and the Negro; nor can we see, either from historical record or observation, how we can escape from considering him as a distinct species.

There are indeed varieties of the human race connected partly with climate and in part with local circumstances. The *Albinos* are white Negroes; and we have seen a female Albino, with an European, produce mulattos. These are sometimes styled *Chacrelas*, sometimes *Don-dos*, and, by Blumenbach, *Luco-Ethiopes*. They are of a pale, dead white; the edges of the eye lids are red; their hair woolly and white; their voice feeble; their hearing dull; their skin soft; and their muscular power weak. They occasionally appear in Europe as varieties; but they are said to be numerous in the isthmus of Darien; sometimes found in the Brasils, in Sumatra, and among the Mongol Tartars, or rather in Hungary. Yet, from comparing the descriptions of Klein and Pallas, we doubt whether the latter are of the Negro race; and we think it rather probable that, like the Cretins of the Alps, they are varieties of the race of their respective countries, weakened from climate or accidents, as we produce variegated leaves, by weak-

ening the plant, either by confining its roots or other means. We are told by Lorry that the Albinos are not sensible of electrical shocks. The swollen throats of the Cretins constitute only an inconsiderable variety. The long handed Quimos of Madagascar we should suppose to be a species of apes, did not the testimony of Rochon lead us as least to hesitate on the subject. Other varieties from customs, as the long flat heads, elephant's legs, the *juncea puella* of Linnæus, when strait lacing was fashionable, with similar deformities, need not detain us.

In various circumstances we find other aberrations from the usual form. In size, men greatly differ; and the diminutive Laplander differs from the mountaineer of Chili (Patagonia) in a far greater degree than the difference of climate will explain. In temperate regions, the size of the human race sometimes greatly varies, and nature sports in a circle whose limits are not very contracted. Dwarfs, we have already observed, have been often stunted in their growth from disease or confinement; but Borulawski, who was only twenty-eight inches high, possessed a perfect form, and mental powers in sufficient perfection. He has been styled a man of sound judgment. He may have been so; but of this we have no evidence: in the lighter graces and accomplishments, and in the more elegant parts of literature, he was well accomplished. Jeffery Hudson scarcely exceeded eighteen inches in height at the age of thirty, and is said to have been lively, witty, and well proportioned. Bebe, who was thirty-three inches, was scarcely a rational creature. The Wottacks, a Lapland race, are said, by the Abbé de la Chappe, not to exceed four feet, and in intellectual powers they are very deficient. On the whole, we have little evidence of the evolution of intellectual powers in bodies whose bulk is limited, or whose growth is stunted by accident or disease. The materialist may employ it as an argument in his own favour, but it is a weak one; for if the body is the instrument of the soul, the agent by which the immaterial principle acts, it will be evident that the display of the faculties of the latter must be limited by the state of perfection which the former has attained.

We must not, however, look for perfection in the overgrown beings which occasionally astonish us by their magnitude. Beyond a given proportion, bulk and height are sources of weakness; for a greater exertion is required to raise a longer lever to an equal height, or to support an equal weight. It is not, indeed, necessary to limit the muscular power, since we know that it differs in different persons; but we seldom find a vast bulk connected with great strength. When it thus happens, the monster is truly formidable. Goliath of Gath could wield weapons of considerable size and weight, but the Irish giant was comparatively weak; and the strongest men have been only of a moderate size. Giants have certainly existed of eight, perhaps of ten feet; but when bones are shown, which, according to their proportion, must give a height of eighteen, or even thirty-six, feet, we may reasonably conclude that the bones of other animals must have been mistaken for human. The greater number of the Patagonians did not exceed nine feet, though some were said to be nearly equal to twelve.

The sexual varieties are most singular, though, fortunately in the human species, less common. In the lower orders of animals the sexes are often united in a

single individual; and, as we rise in the scale, anomalies in these respects are more uncommon. We shall only mention, in the quadrupeds, the circumstance of the free martin. When twin calves are produced, and the one is female, she never breeds. It is the "taura" of the *scriptores rei rusticæ*, fattens freely, is of a more delicate fibre than the bull, and bellows like the ox. Mr. Hunter found it, on dissection, of neither sex. We mention this chiefly to add that it is not an universal rule, for we have known a free martin breed; and this peculiarity is not found in the human race, for the twin female is always perfect. Indeed anomalies in these organs are very rare among mankind, and we have said that the reputed hermaphrodites are generally female. The variations in individuals, the *lusus naturæ*, do not belong to the history of the human race, and are scarcely the objects of this work, as they admit of no practical application. A full account of these misfortunes of mankind may be found in Cheselden's Anatomy, Dr. Parson's Essay, and the first numbers of the Edinburgh Medical and Surgical Journal, to which the reader who is curious on this subject may be referred, and in these works he will receive full information.

Climate, though it may not influence the colour of the skin, greatly varies the forms of mankind. We have, in part, anticipated this subject, in the article *COLD*, q. v.; and have already mentioned the diminutive form of the Lapland race, though naturalists do not give full credit to the Abbé de la Chappe's descriptions. The most general source of the population of the globe, the family that escaped from the general destruction of the deluge, was placed in the high mountains in the centre of Asia; in a climate temperate from its height; fertile from the numerous rivers derived from its elevated plains; in short, a spot in which the human race may be expected to reach, and in which it apparently did reach, all the perfection of which the species was susceptible. Asia was the parent of the Goths, the Greeks, the Arabs, who attained successively the dominion of the world, and established their power in every region where they carried their arms. Heat or cold has not greatly changed them; but there are apparently other races, in different circumstances, greatly affected by their situation, either as it is cold or hot, wet or dry.

Moderate cold, alternating with a more temperate air, gives firmness and solidity, increases the muscular power and the mental energy; gives animation, ingenuity, and activity. It is not, however, the temperature best adapted for the more perfect evolution of the form. From the thirty-fifth to the forty-fifth degree of northern latitude, in features, stature, and proportion, mankind appear most perfect, at least those of the Asiatic or Gothic race. When we approach nearer the equinoctial line, men lose their energy and activity, while the spirits and imagination appear to be animated to a degree which occasions uncommon, and often irregular, exertions of fancy, new, unexpected combinations.

Every race, however, is not equally affected by heat or cold. The Asiatic, we have said, seldom loses his pre-eminence, wherever he is placed. The Negro bears with impunity the greatest heat, and the tropical sun seems his natural climate. The Ethiopian feels no

inconvenience from the burning sun, but becomes torpid in a temperate climate.

The differences in the human race occasioned by dryness or moisture vary as these are connected with heat or cold. Dry countries render the fibres rigid, the inhabitants thin, active, laborious, irritable, but courageous, and capable of the greatest enterprises. When combined with heat, the active spirit, the enterprise, is less, but the ingenuity apparently greater. Such were the Greeks, on the barren rocks of the Archipelago: such were the Moors in Spain, the Arabs on the banks of the Euxine. Humidity, on the contrary, softens the fibres, renders the body flaccid, the mind dull and inactive, but capable of much labour, cool and persevering. The inhabitants of such countries receive an impulse slowly; but, when impelled, steadily persist. Such were formerly the Bœotians: such are now the inhabitants of Holland, the Low-countries, and the Swiss of the valleys. When heat is united with humidity, the inhabitants are softened and weak, incapable of labour or active enterprise, as the slightest motion is highly inconvenient. They are indolent and contemplative; but their meditations are seldom directed to important purposes, and they have never made any improvement in science. Their utmost efforts are exhausted in patient industry, in works of imitation, and which require little exertion. Such are the inhabitants of Bengal, of Ava, of Guiana, &c

Extreme humidity, with cold and a stagnant atmosphere, produces swellings of the lymphatic glands, goitres, and cretinism. The Cretins are an insensible race, with little pretensions to the character of rational creatures, whose organs are generally relaxed. The glands of the neck are enlarged, and hang down in the most disgusting bags. They are of a yellow paleness: their limbs are pendulous; their look stupid; they cannot stand upright, nor speak; and continue in a lying or sitting posture through their whole lives. They must be attended, fed, and dressed like children. They are, however, revered as the favourites of Heaven; but are chiefly distinguished by their gluttony and lasciviousness. This affection is not conveyed to their children; but they are usually disposed to it. Cretins are found in the defiles of all the high mountains, even the Cordelieras and the Andes.

The qualities of the air correspond with those of the ground; and, in general, fertile lands produce handsomer, more active, and more intelligent men than those which are barren. Yet the latter have more spirit, activity, and independence than the former, who are generally indolent, effeminate, and the slaves of despotism. It has been fancifully said that there is an analogy between the inhabitants of every country and its animals. Thus the Laplander is supposed to be analogous to his reindeer; the Muscovite to the bear; the Tartar to his horse; the Samocide to the phoca, or sea-cow; the Malay to the tiger; the Negro to the ape; the Bedouin to the camel; the Indian to the cow; the Papouan to the hog; the Moor to the hyena; the Chinese to the cat; the Peruvian to the lama; the Canadian to the weasel (*Virey*). Perhaps the peculiar manners may, in each instance, be influenced by climate.

The nature of the food produces some change in the constitution and on the mind of man. We have spoken on this subject, as it relates to individuals, under the

article *DIÆTA*. We must now speak collectively of its effects on the different races of mankind. The great outline of distinction is between the northern and southern race; those who live principally on animal food, or those whose nourishment is chiefly taken from the vegetable kingdom. Man, we have said, is calculated for a mixed aliment, and such he uses when both can be easily procured; but the savage of the woods will not patiently wait for the growth of his corn, when he can pursue and kill the deer; and the inhabitant of the arctic circle is from necessity obliged to devour his rein deer. The inhabitants of the northern regions, who eat large quantities of animal food, are consequently robust, active, enterprising; those of the south, timid, weak, and indolent. The climate, in each case, influences the character; but we generally find, even in this country, warmth induce a dislike for animal food, and render vegetables more pleasing. It is remarked by curious observers, that food differs with the latitude. The Greenlander, the Canadian, and the Kamtschatdale eat with greediness the rancid fat of their whales; the Swede, the German, and the Englishman, use a large proportion of flesh. The Frenchman eats less of animal food, with a larger proportion of bread; the Italian his legumina, his polenta, and macaroni; the Turk his rice; the Moor his figs; the Negro his millet and durra; the South American his maize; the white African, on the shores of the Mediterranean, his dates, figs, and lotus (*ziziphus lotus*); the Malay his sago and bread fruit; the maritime races their fish; the Caffres, the Hottentots, and Arabs, principally their milk, adding occasionally the flesh of their numerous flocks; the Mongols and Calmucks the flesh of their horses, with their milk sometimes mixed with blood; the Persians and Egyptians their dates and water melons; the inhabitants of the Archipelago their figs and chestnuts; the Californians the fruit of the nopal, or cactus; the Brasilians the acajou apple (*anacardium occidentale*); the Peruvians and Mexicans the cassada, potatoes, and yams; the Abyssinians the seeds of the sesamum; and the Cingalese the *cynosurus coracanus*. In Africa millet is so cheap, that it is computed a hundred men may be maintained during a whole year for less than nine pounds sterling. The form of the teeth and jaws differs with the food. The teeth of the Negro are thick, large, and distant; the muscles of mastication weak; the jaws elongated. The Tartars, a carnivorous race, on the contrary, have smaller, sharper teeth, strong jaws, and powerful muscles. The powers of digestion are strong in the higher latitudes, and the inhabitants can digest easily the fat of their whales, and the blood of their sea calves, while the Indian bramin requires aromatics to assist the digestion of his fruit and rice.

The natural drink of the human race is water; but every nation is eager to attain a state of intoxication. In the north only it is most easily and safely borne. In the south it produces madness; and Mahomet and Zoroaster have consequently forbidden, by the most positive precepts, the use of fermented liquors. The inhabitants of the south calm their too great sensibility and activity by cooling and acid, or by narcotic, drinks. The tea of eastern Asia, the coffee of Arabia, and the beer of the northern nations, in which they infuse the *agaricus muscarius*, are of the latter kind: the opium and the bangué of India are similar in their effects, and employed

in the same way. The cooling, diluting drinks temperate the too great heat of the warmer regions, while the narcotics check the too great irritability, though they leave the nervous system more peculiarly susceptible of irritation, till the excitability is wholly destroyed.

Having traced the varieties of the human race in every circumstance and situation likely to influence them, we must more particularly attend to minuter distinctions. The chief of these is sexual. Man has, in general, superior stature, larger and stronger muscles, a larger brain, stronger bones, a deeper voice, a browner and a more hairy skin. Women have long, fine, and flexible hair, a delicate white skin, soft flesh, a rounded form, a soft voice, a lively sensibility, though often irregular, and a very irritable system of nerves. The body of a man is larger and more expanded above, that of a woman below, the waist: each is thus adapted to their several offices. The infant resembles a woman in its constitution and characters: a woman beyond the change of life comes nearer the man. A woman has the sanguine complexion, the nervous irritability, and the weak muscles of the child. She is also variable, credulous, subject to the influence of imagination, and to nervous diseases. Man is proud, naturally harsh, firm, and independent. Woman, soft, gentle, gaining by address rather than violence, yielding to conquer. Though we should not consider, observes M. Virey, the females divided into as many races as man, yet we shall find considerable variations in the beauty of women. "In the north they are fairer than the men, and their dazzling whiteness often becomes insipid. All the southern women are brunettes, more or less poignant; but the most beautiful of the sex inhabits the temperate climes of Europe and of Asia. The most beautiful French women are found about Avignon, Marseilles, and in the ancient Provence, formerly peopled by a Greek colony of Phocæans. The most beautiful Spanish women are found, it is said, about Cadiz; the most agreeable Portuguese in the city of Guinamarez. Beautiful women are found in many parts of Italy: the Sicilian and Neapolitan women, descended from the ancient Greek colonies, are also charming. The Albanese are well made; the Chian women delightful; those of the Ægean Archipelago are fair, lively, and agreeable; and, like all the Greeks, have large and very beautiful eyes." The Circassian, the Mingrelian, the Cashmirian, and the Georgian women are, however, admitted to be the most perfect models of the female form, though surrounded by the most ugly races of mankind, the Calmucks and the Nogais Tartars, whose women are equally disgusting, though the air, the situation, and manner of living, are the same. The race is, however, essentially different. The female slave merchants of the east assert, that the women are always plain where the ground is sterile, and the water bad. The Persians, it is said, were a mean ugly race, until meliorated by the beautiful slaves of Cashmire and Georgia. The common people still continue to possess little dignity or beauty.

The manners of women are dignified and correct where they are less numerous than men, as in the northern regions; less so when they are more numerous. In the latter polygamy usually prevails, which has been occasionally considered as a cause, and sometimes as the effect, of a greater proportion of females. It is asserted, that, among a stronger race of men, the proportion of

male children is greater; but this is by no means certain: and it is more probable that the extraordinary female population of the east is an unexplained effect of polygamy. In Cairo we find one sixth more of women than of men; in India one fifth; in some countries of Asia, one fourth; at Bantam and in the islands of the eastern ocean, there are said to be six women to one man. In Thibet the proportion is probably reversed; since we are informed, by the latest travellers, that a woman has usually many husbands, on whom she revenges the injury her sex sustains in the harems of Turkey.

The want of any essential organ in generation wholly changes the peculiar sexual form. This we know, by frequent experience among animals, and it occurs in the human race. We had lately a record of this kind, where a woman experienced none of the changes which usually take place about the time of puberty; and it was, on dissection, found that the ovaries were wanting. When the form in either sex approaches to that of the other, there is generally some defect either external or internal, and sterility is often the consequence. Divorces on account of sterility are consequently justifiable in the eye of reason; though, from political views, they are countenanced in few of the more polished nations. Indeed, we have seen in the late distracted state of France, that the facility of procuring divorces occasioned the most infamous, disgraceful scenes.

Fertility is in proportion to the general health and the regular moral conduct of married people. The number of children, from one marriage, is computed in Iceland to be from fifteen to twenty; in Flanders from ten to twelve; in Germany eight, and England six to eight; in France from four to five; and in Spain from two to three. Women of a sanguine temperament, of a gay affectionate temper, are the most fruitful: those of a thin dry habit, of a warm eager temper, violently passionate; or, on the other hand, indolent, phlegmatic, and void of affection, less so. Nearly the same differences are observable in men. The end of the winter or the spring is most favourable to conception; for the greater number of births occur in autumn or the early period of winter.

Maritime countries have been usually most prolific, it is said, on account of the fish diet. Cold and moist air are supposed to be favourable to conception, while dry and hot countries are the opposite. Yet the negroes in Africa are reported to be prolific; but their constitution is peculiarly sanguine. The use of the baths in women, and the constant sitting on a horse in men, are said to be equally unfavourable to generation. Too great fatness or leanness, too violent passions, an exhausted constitution, intemperance, excess of venery, and unnatural indulgences, are equally causes of sterility. Women who have had many children are usually healthy and long lived: the single women affected with a variety of diseases. Women are more frequently barren than men impotent.

The various observations of travellers have shown that the multiplication of the human species proceeds more rapidly in cold, poor, less civilized countries, and probably in republics; while, on the contrary, a temperate climate, a high degree of civilization, with a moderately fertile soil, despotically governed, are less favourable to it; and it is still less rapid when these

circumstances exist in a greater degree. In the first case the men are laborious and active; their manners simple: in the second, they are ingenious and industrious; but, from a more sedentary and a more debilitating course of life, less vigorous and active. In warmer climates, and a more luxurious state of society, they are indolent, weak, and their powers in a great degree exhausted.

The lists of births in the different countries of Europe have shown, that villages and cities, where the population is numerous, and riches equally distributed, are more fertile than opulent cities; and that seasons of scarcity are injurious to population. Thus early Rome furnished numerous armies: under the emperors the armies were supplied by mercenaries. Russia and Sweden abound more in strong, active men, than Spain and Portugal. In Russia, it is said, the births are nearly one twelfth or one fifteenth of its population, and the deaths only about one in forty-five. Perhaps, if the whole of England be considered in one view, the deaths will not be more considerable; or, at most, will amount to one in forty.

The life of man is said, by the psalmist, to be three-score years and ten. Various are the instances in which, even in these times, it has been supposed to have extended beyond the hundredth year; but the greater number of these are fallacious: and, as we were once told by a woman whom we had detected in a fallacy in this respect, old age is a profitable profession. Many ages have been extended by vanity, some by the neglect of registers, or the mistake of persons; and, in general, we can scarcely rely on the accounts of any who are said to have exceeded a century. Prior to the deluge the age of man seems to have been more considerable; but the great object of the Mosaic narrative seems to have been the preservation of the genealogy of the children of Israel from Adam, and we may reasonably conclude that, in continuing this succession, families or dynasties may have been represented as individuals. No change in the constitution of the globe, in the lives or situations of inferior animals, are recorded: we have no reason to suppose that the descendants of Noah were in any respect different from his parents. In these times we are told by Buffon that one fourth of those who are born die before the end of five years; one third before the age of ten; half before they have completed the thirty-fifth year; two thirds before the fifty-second; three fourths before the sixty-first. He adds, that the mean life of a child of three years is thirty-three years; that of a man of twenty-one is nearly the same. The life of a man of sixty-six is nearly of the same value with that of an infant just born. Many other observations of this kind might be suggested, if it were a proper subject of this work; but, in general, the probabilities of human life are taken from the records of great cities, where life is much more precarious than in the country. The insurers and the calculators of tontines and benefit societies have fatally experienced the fallacy of such statements, when their members are promiscuously taken from large cities, towns, villages, and the country. The lives of women are said to be shorter than those of men, and of single women than of single men.

The commencement of spring and the end of autumn are supposed in Europe to be the most fatal sea-

sons; but Dr. Heberden has shown that in England a larger proportion of mankind die in the winter months. It is probable that the cold in winter, so fatal to the weak and aged, may occasion the difference. When a thaw succeeds a severe and continued frost, deaths are more numerous, chiefly confined to the aged, and those labouring under chronic diseases of the lungs. In Asia there are two fatal periods, viz. the change of the seasons.

The ages most fatal are the changes of life, viz. the appearance of the teeth, the period of puberty, the period between twenty-one and twenty-eight, when the constitution has not yet attained its firmness; the time of the cessation of the menses in women; and the period when the generative faculty decays, or is lost, in man, about the age of sixty-three. On this foundation the ancients established their doctrine of climacterics; a system not wholly visionary, though refined too far, and mixed with numerous fancies.

Cold and dry countries are most favourable to the duration of life; and when moderately fertile, so as to require steady exertion, still more so. Some races and some families seem to have a peculiar claim to longevity, while the inhabitants of hot climates, who soon ripen, decay prematurely; and, in many families, we have known it a rare occurrence to find a person of the age of sixty. Those whose minds and bodies evolve slowly, are more often long lived than those who astonish by an early vigour and spirit; so that the usual axiom is not wholly without foundation—"so wise so young, will not live long." Hermogenes, Crichton, and Barratier, are instances of premature genius, with short lives. The early and astonishing acquisitions of very young men in different arts and sciences, also, seldom lead to acknowledged excellence in more advanced age. Sanguine temperaments are said to be longer lived than the bilious or melancholic; but this we suspect leans too much on a doubtful theory. Very tall or very short people seldom reach, it is said, to a great age; but a person rather short than tall, rather thin than fat, muscular, firm, and with a full chest, has apparently the fairest claim to longevity. An active life, with little uneasiness, a dry free air, early hours, a mind occasionally engaged, but not exhausted, a cheerful disposition, frequent changes from country to town, a diet regular, rather in times than always in quantities, with moderate passions, seem chiefly to contribute to an extended healthy old age.

Yet every thing must have a termination: each living being is born, grows, decays, and dies. In living bodies we find two principal forces which regulate their existence; the power of expansion and decay. The youth expands in bulk; his arteries are daily fuller, larger, longer; his nerves gradually firmer; his functions more active and powerful. When old age approaches, the veins are filled, and the arterial system acts more weakly; the irritability is less; the functions more weak; the glands are diminished in bulk; the fat absorbed; the fluids more thin and more acrid. The arteries can no longer conquer the accumulated load in the veins, the brain is overloaded, or serum exhalates in the abdomen or under the skin; the vessels of the glands cannot propel their fluids, and these are infarcted; the nerves no longer possess their former irritability; and the senses decay. From all these causes

the limbs grow stiff, the arteries ossify, the whole system is oppressed with a load which it cannot overcome, and man sinks to mix with his parent dust. Such is the lot of all! Noctes atque dies patet atri janua ditis!

See Buffon's Natural History (edit. de Sonnini). Herder on Man. Virey Histoire Naturelle du Genre Humain, 2 vol. 8vo. Vieq. d'Azyr Traité d'Anatomie, Introduction. Camper's Works, translated by Cogan. White on the Gradation of Man. Halleri Elementa Physiologiae. Cuvier Anatomie Comparée, 4 vol. 8vo. Bell on the Expression of the Passions. See FÆTUS, GENERATION, HÆMORRHOIS.

HOMOGE'NEUS, (from ὁμοσ, like, and γειος, kind). An uniform body, or mixture.

HOMOLI'NON, (from the same, and λινον, flax). CRUDE FLAX, or coarse cloth, of which towels were formerly made in the public baths.

HOMONOPA'GIA. See CEPHALALGIA.

HOMOPHA'GIA, (from ὄμος, a shoulder, and φαγω, edo). A SACRIFICE; from the shoulders being assigned to the priests. The shoulders of the deer are still the privilege of the keepers; and an execution is, with an indecorous levity, still called a *shoulder feast*.

HOMOPLA'TA, (from ὄμος, the shoulder, and πλάτα, the blade bone). See SCAPULA.

HOMORU'SIA. A medicine mentioned by Avicenna.

HOMO'TONOS, (from ὄμος, and τεινω, to extend). Equable; an epithet for a continued putrid fever, which preserves the same tenor through all stages.

HOMU'NCULUS PARACE'LSI, (a dim. of homo, a man). See ADOLESCENS.

HOPLOCHRI'SMA; Χρισμα το ὀπλου; the SALVE of the WEAPON, said to cure wounds by sympathy, that is, by anointing the instrument with which the wound was made; a ridiculous fancy, scarcely even in the last century obsolete.

HORÆ'OS, (from ὄρα, season). According to Hippocrates and Aurelianus it means in proper time; τα ὄραια signifies the catamenia observing a regular period: a similar phrase was not long since retained in Scotland, the *ordinary*. Strictly, the fruit ripe about autumn; but in modern authors any ripe fruits.

HORDEA'CEUM VI'NUM, (from hordeum, barley). See ALLA.

HORDEO'LUM, STIAN, (from hordeum, barley,) CRITHE, which see. A tubercle on the eyelids, resembling a barley corn in shape. It is small, red, hard, painful, encysted, and immoveable; containing a thick matter, and seated either in the in or outside of the eyelid. Dr. Aitken styles it a wen; but Dr. Cullen places it as a variety of *phlogosis phlegmone*. See Wallis's Nosology. Bell's Surgery, vol. iii. p. 264.

HORDEO'LUM HYDATIDO'SUM. See AQUILA.

HO'RDEUM, (ab horrore aristæ, from the unpleasantness of the beard to the touch). BARLEY. In the shops barely occurs in two forms, viz. *hordeum distichon* Lin. Sp. Pl. 125; *hordeum Gallicum vel mundatum*; and COMMON OR SCOTCH BARLEY, and *hordeum*. The common or Scotch barley is the *hordeum vulgare* Lin. Sp. Pl. 125.

Barley is less nutritious, less glutinous, and more cooling than either wheat, oats, or rice. It was the principal aliment and medicine amongst the ancients in acute diseases; but the common barley, freed from the

shell in mills, and called *French* or *Scotch barley*, is generally used. A sort of shelled barley is formed into small round grains in Holland and Germany, and called *pearl barley*; of which are three preparations, made in the following manner:

Decoctum hordei. Barley water.—R. Hordei omni cortice nudati. p. ʒ ii. aquæ distillatæ m. ʒ iv. The barley is first to be washed, and cleared from all adhering substances, in cold water: about half a pint of water is next to be poured upon it, and boiled for a little time.—This liquor is to be decanted, and to the barley the distilled water added, boiled to two pints, and strained for use.

Decoctum hordei compositum, olim decoctum pectorale. Compound decoction of barley, or pectoral decoction.—R. Decocti hordei m. ʒ ii. uvarum passarum acinis exemptis: caricarum incisarum, singulorum, p. ʒ ii. Glycyrrhizæ incisæ et contusæ, p. ʒ ss. Aquæ distillatæ, m. ʒ i. Decoque ad libras duas, et cola.

Decoctum hordei cum gummi. Decoction of barley with gum.—In two pints of the decoctum hordei, whilst warm, one ounce of gum arabic is to be dissolved.

The decoction of barley with gum is a useful diluent and demulcent in strangury and dysury; for the gum mixes with the urine, and sheaths the urinary canal from the acrimony of this excrementitious fluid.

Decoctions of barley in water contain their lighter and more agreeable parts, and are useful as an article of diet in acute and inflammatory disorders; but are most useful when accompanied with mucilaginous medicines, to assist their union with the blood. Barley, in its malted state, is also antiseptic, and an useful alterative. See BRASIAM.

HO'RDEUM CAU'STICUM. See CEVEDILLA.

HORIZONTALIS, (from ὁρίζων, the horizon). In botany it is the epithet of a flower, whose disc grows parallel to the plane of the horizon.

HO'RMINUM, (from ὀρμαίνω, to excite,) from its supposed qualities in provoking venery. CLARY; *gallitrichum*; *sclarea*; *orvala*; GARDEN CLARY; the *salvia hornimum* Lin. Sp. Pl. 34; is a whitish, green, slightly hairy, plant, with square stalks, on the tops of which are long spikes of bluish flowers; perennial; a native of warmer climates; cultivated with us in gardens; and flowering in July and August.

The leaves are bitterish, have an aromatic, but to many a disagreeable, smell; and are recommended as antispasmodic. Their active part resides in resinous matter, which is wholly taken up by spirit of wine; and, on inspissating the tincture, remains in the extract. Water takes up a part of their virtue by infusion; and in distillation carries it wholly over. The seeds possess the same qualities as the leaves. The flavour of the clary, in a small proportion, communicates to sweet wines that of frontinac.

HO'RMINUM SYLVE'STRE. WILD CLARY; *sclarea Hispanica* and *oculus Christi*. *Salvia sylvestris* Lin. Sp. Pl. 34. This species resembles the former in appearance, but in quality is much inferior. See Raii Historia.

HORN. See CORNU.

HO'RROR, (from horreo, to shake with cold). A tremor is the vibration of one limb only; refrigeration a great coldness; perfrication when coldness is accompanied with a gentle unequal motion of the skin, or

shivering, called *phricasmus*; an horror is, when the coldness of perfrication is considerable, and attacks by fits, affecting the skin only. (See FEBRIS.) A rigor is an irregular agitation of all the body. See RHIGOS.

HO'RTUS, a GARDEN, (from orior, to arise; the source of vegetation). See PUDENDUM MULIEBRE.

HO'RTUS LETITIE. See CROCUS.

HO'SPITAL. See NOSO COMIUM.

HO'UI POUN. See TINCAL.

HUAXACENSIS, HUICIPO'CHOTL; *Ricinus Nova Hispaniæ*; a species of either croton or jatropha not easily ascertained. Hernandez describes it as a shrub which creeps like a vine, with a fruit like a hazel nut, the kernels of which operate gently upwards and downwards, but not violently.

HUILE DE GRANDE BAYE. See CETUS.

HUMERA'LIS ARTERIA; (from humerus, the shoulder). The HUMERAL ARTERY arises from the lower and fore side of the axillaris, and runs backward between the head of the os humeri and teres major, surrounding the articulation, till it reaches the posterior part of the deltoides, to which it is distributed. In its course it gives off several branches to the neighbouring parts. A puncture of this artery, near the shoulder, though the hæmorrhage may be restrained by ligature, will probably, it is said, be followed by a fatal mortification unless the arm be amputated at the joint.

HUMERA'LIS MUSCULUS. See DELTOIDES.

HUMERA'LIS NERVUS. See CERVICALES.

HU'MERI OS. The BONE of the ARM; *adjutorium*; is articulated by its head, which in children is an epiphysis, to the scapula: immediately below the head is the neck of the humerus. This bone grows broader at its lower extremity; and at the end is formed into two condyles, on the external of which the head of the radius moves; and, in the cavities, between these condyles, the ulna.

HU'MERUS, (from ὀμος, omos; *adjutorium*; the SHOULDER, or joint which connects the arm to the body; the head of which is the olecranon. In Hippocrates it is called BRACHIUM, q. v.

HU'MILIS, RECTUS MUSCULUS, (from humi, on the ground, because it turns the eye downwards). See DEPRESSOR OCULI.

HUMIRU'BUS. DEWBERRY, (from humi, on the ground, and rubus, a bramble). See RUBUS IDÆUS.

HU'MOR, (ab humo, because moisture springs from the ground). HUMOUR. A general name for any fluid; particularly applied to the fluids of the human body, and often to these in their morbid state. The term is used without any reference to disease, in speaking of the fluids of the eye; and popularly employed as synonymous with disposition; in the time of Shakspeare and Jonson greatly abused by an indiscriminate application. The ancients seem to have called the nutritious juices the radical humours.

HUMORA'LIA, (from humor, a fluid). In Linnæus's Nosology it is an order of diseases in the class vitia; and signifies disorders attended with vitiated or extravasated fluids.

HUMORA'RIA, (from the same). A continued fever, in Sagar's system, apparently inflammatory, attended with a vitiation of the fluids.

HU'MULUS, (from humus, the ground). See LUPULUS.

HUMUS NIGRA PICTORIA. See CRETA NIGRA.

HUNGARICA A'QUA, vel HUNGARICUS SPIRITUS. See ROSMARINUS.

HUNGER. See FAMES.

HURA, (from *hura*, in Spanish, a knob, from its round fruit). The SAND BOX TREE; JAMAICA WALNUTS; *warnelia* and *havelia*, *hura crepitans* Lin. Sp. Pl. 1431, is a native of the Spanish West Indies; the leaves of which are full of a milky juice, and the seeds purge upwards and downwards. The shell, after the seeds are taken out, is used as a sand box.

HU'SO. See ICHTHYOCOLLA.

HUTZO'CHITL. See PERUVIAN. BALS.

HYACINTHUS, (from *ἵα*, a violet, and *κίθος*, a flower, from its colour). It is poetically said to be named from the friend of Apollo, who was turned into this flower. HARE BELLS. *Hyacinthus non scriptus* Lin. Sp. Pl. 453. The roots are bulbous; the flowers agreeably scented, and of a purple or blue colour. The plant is found in woods and hedges, and flowers in May. Galen thinks the roots anticteric; and they are sometimes supposed to be astringent.

HYACINTHUS STELLARIS. See LILIO HYACINTHUS.

HYACINTHUS RACEMOSUS MOSCHATUS. See BULBUS VOMITORIUS.

HYALODES, (from *υαλος*, glass). An epithet applied to urine which deposits a white, shining sediment.

HYALODES, (from *υαλος*, glass, and *ειδος*, likeness,) the vitreous humour of the eye; or rather its capsule. See OCVLUS.

HYA'NCHE, (from *υς*, a swine, and *αγγυ*, to strangle). A quincy, accompanied with an external tumour on each side the throat, like the swellings on the necks of swine.

HYBERNACULUM, (from *hyberno*, to winter). That part of the plant which encloses and secures the embryo from injuries during the winter, expanding in the form of buds on the approach of summer.

HYBOUCOU'HU AMERICA'NUS. The name of an American fruit, of the size of a date, but not eatable; whose genus is unknown. The oil expressed from it is kept in the shell of a fruit called *carameno*, and has sometimes the same appellation. It is chiefly used against an American disorder called *tom*, which seems to be the same with *chigres*, or a collection of very small worms in the flesh.

HYBRID. A monstrous production from two different species of plants or animals; generally barren.

HYDARTHROS, (from *υδωρ*, water, and *αρθρον*, a joint,) a clear water which issues from wounded joints; and a name of the *synovia*.

HYDARTHROS, (from the same). A WHITE SWELLING. Dr. Cullen places this genus in the class *locales*, and order *tumores*, which he defines a tumour of the joints, chiefly of the knee; at first the swelling is slight, of the same colour of the skin, very painful, diminishing the mobility of the part affected.

Mr. Bell, in his Treatise on Ulcers, speaks of this disease under the name of white swellings of the joints, and distinguishes two species, viz. the *rheumatic* and the *scrofulous*: each is more frequent in the large than in the smaller joints. The first species begins with an acute pain in the joint, and frequently the tendinous

aponeurotic expansions of the muscles connected with it. There are, from the beginning, an uniform swelling and tension of the surrounding teguments; but, in this period of the disorder, the skin is discoloured. The patient, from the beginning, suffers much pain from motion; and finding it easier in a relaxed posture, keeps it bent; which, especially in the knee, renders the flexor tendons of the limb rigid, and in time stiff. The swelling gradually often increases to thrice the natural size of the part. The cuticular veins become turgid and varicose; the limb, below the swelling, decays, or becomes œdematous; the pain increases, especially if the patient is warm in bed; and abscesses form in different parts of the swelling. In these abscesses a fluctuation is evident on pressure; but the swelling is elastic, and rises when the pressure is removed. These different collections, when they break or are laid open, discharge matter; at first of a good consistence, but soon degenerating into a thin fetid sanies, without apparently diminishing the size of the swelling. The orifices, if not kept open, soon heal, and new collections, forming in different parts, again break out and heal as before: at last the whole surrounding teguments are covered with cicatrices; but the patient's health hath suffered considerably in the interval, first from the pain, which destroys both sleep and appetite; and secondly, from the absorption of matter, producing a quick pulse, night sweats, and diarrhœa. These changes occur independent of any affection of the bones of the joint; but when by a continuance of the complaint the ligaments are eroded, the cartilages, and even the bones, soon suffer. Though such are the appearances recorded, and usually confined to the first species, yet we are confident that they are peculiar to the second; and though they sometimes occur in hydarthrus from rheumatism, yet it is only when the rheumatic inflammation has produced the scrofulous. The causes of this species are strains, affecting the ligaments of the joints, so as to produce inflammation; bruises, luxations, or rheumatic disposition. This species of white swelling occurs most frequently in young plethoric people: the swelling is confined to the soft parts, and is from the beginning evident. When such swellings occur in young, strong, plethoric persons, and especially those who have been subject to rheumatism, they are generally of the rheumatic species. The rheumatic white swelling is always inflammatory, and bleeding will be the best remedy; at first from the arm, and afterwards from the part affected. Cupping and scarifying are useful remedies; and at least eight or ten ounces of blood should be discharged from each side, repeated at proper intervals, according to the violence of the symptoms and strength of the patient. Cupping is preferable to leeches; but when the swelling of the joints is considerable, it is impossible to procure a sufficient quantity of blood by this operation, and leeches must be applied. On the anterior part of the joint, where the cupping glasses or leeches have not been placed, a blister should be put; and the part be kept open, till the wounds from whence the blood was discharged are so far healed that a blister may be laid on one side of the joint; and, as soon as this is nearly healed, the other side should be also blistered. By thus alternately applying them, first to one side, and then to the other, almost a constant stimulus is kept up; from which the greatest advantages are derived. Cooling laxatives are necessary at proper

intervals; as well as a strict antiphlogistic course of diet. In the first stages only this or any other plan can be beneficial; and in these cures are sometimes effected. When the original inflammatory disease is removed, the drains should be stopped, and while there are yet no appearances of the formation of matter, mercury has been sometimes recommended for a few weeks, to keep the mouth merely sore. This medicine can, however, be only useful in the case just suggested, of the inflammation exciting the action of scrofula; and indeed the mode in which it is advised shows that the friction is of as much service as the remedy; for the proportion of mercury in the ointment is so small, that two drachms of the ointment must be used three times a day; and in order to rub in this ointment with advantage, an hour should, it is said, be spent each time in rubbing. Falls of warm water on swellings of this kind are strongly recommended by Le Dran, &c. By a proper use of the several topical evacuants in the first or inflammatory state of the disease, and afterwards, previous to the formation of matter, of mercurials and friction in the second stage, many have been cured. When by the bent position in which the limb has long been kept the use of the joint is lost, pure olive oil may be applied warm: as much as can be easily consumed by an hour's gentle friction should be rubbed in, three times a day, extending the friction over all the muscles around. Gentle action of the parts as soon as it can be borne, as recommended by Mr. Pugh, on the Utility of Muscular Motion, is highly beneficial. Should suppuration come on, opening the different abscesses soon after their formation may probably prevent the matter from injuring the capsular ligaments of the joints; the destruction of which renders amputation necessary.

In the second species the pain is usually more acute, but more confined to a particular spot, about the middle of the joint. The swelling is at the first inconsiderable; and little difference is seen in the size of the affected joint. The least motion gives great pain; so that stiffness and rigidity are equally produced by the position. As the disorder advances, the pain is more violent, the swelling increases, and the ends of the bones that compose the joint grow large. A very peculiar elastic swelling at last is felt; varicose veins appear over its surface, and collections of matter occur in different parts of it: these, when they burst, or are laid open, discharge considerable quantities of a glairy or purulent matter, but more frequently a thin fetid sanies; and, if a probe can be passed down to the bottom of the sores, the bones are found carious, and pieces are often discharged at the openings. As the disorder continues, the constitution suffers; a diarrhoea, with night sweats, comes on, and the patient is reduced to extreme weakness. From every symptom, and appearance on dissection, this species seems evidently to be an affection of the ligaments, and next of the bones; the surrounding soft parts only suffer from their connection. This species sometimes appears to be the consequence of an external accident; but generally begins without the patient's being able to account for it. From the effects usually produced on the bones which it attacks, it would appear to be a species of the real spina ventosa, and truly scrofulous. This species of white swelling is indeed often either attended with other evident symp-

oms of scrofula, or occurs in those descended from scrofulous parents. When any perceptible swelling appears, the bones are found to be the parts chiefly affected, and the surrounding teguments suffer only in the progress of the disease; and when in such patients as are evidently of scrofulous dispositions, if the disorder has begun without any, or from a very slight, external cause, we need not doubt its being of a scrofulous nature. In the small joints, when the diseased parts of the bone begin to cast off, a cure may be sometimes promoted by assisting the efforts of nature; but in all the large joints, particularly in the knee and ankle, amputation will often afford the only means of relief.

The remedies usually employed are those of scrofula, with topical stimulants to the part, to increase the action of the vessels, and to promote the absorption of the matter. We shall not anticipate the article scrofula by enlarging on its causes and the manner in which its remedies relieve, but merely remark that the applications of marine plants, sea bathing, and drinking salt water, are the most effectual remedies. They act slowly, but are more successful than any other plan. The burnt sponge, which consists of alkaline or neutral sals, with animal oil, is often serviceable; and the burnt cork has had its advocates, though a remedy of inferior powers. Small doses of calomel are sometimes useful, and the bark is occasionally given, when fevers come on, or the night sweats appear to exhaust the patient. Neither of these latter remedies, however, is peculiarly adapted to the complaint.

The topical applications of most service are blisters frequently repeated; and sometimes the mercurial ointment, in the manner already described, has been found useful. Hemlock has been more frequently applied externally than given as a medicine; but in either way it seems of little benefit, and, when joined with the arum root, its utility is but little increased. A variety of other applications are recommended, but of inferior efficacy.

Practitioners have differed respecting the opening of the tumours of the joints, and, in general, it seems to be decided that they should be left to nature. It is at least certain that the wounds are with difficulty healed, and that the disease is sometimes removed without the discharge of the glairy matter, which fills the place of pus. We have had occasion to doubt the propriety of this decision; and though we allow that the cavities of joints should on no occasion be exposed, we greatly doubt whether the constitution would not be spared by the early discharge of matter which is never salutary, but, when retained, produces hectic, and symptoms of the greatest danger.

Amputation, in cases of white swelling, ought never to be advised till the complaint is far advanced; it has been observed, that amputation has more frequently succeeded when the patient was previously much reduced by diarrhoea. If this be true, we should never have recourse to the operation, until every probable means of saving the limb has been tried in vain.

On dissection of the joint, a great thickening of the ligaments, which confounds the several parts, is observable, together with sinuses, formed by crude matter, through this distinguishing mass; and generally an erosion of the cartilages at the end of the bones.

HYDATINON, (from *υδαγ, aqua*). The name of an ancient collyrium, made of rain water.

HYDATIS, (from the same). See AQUILA.

HY'DATIS. A HYDATID. (See PELYCTENÆ.) Hydatid, considered as a genus of disease, has been placed by Dr. Cullen among the local diseases in the class *tumores*. It has been found, however, to possess an independent life, and has been referred to the vermes intestinales, characterised as a vesicular body, at least posteriorly; and terminated anteriorly by a head furnished with three or four antennæ, with or without fangs. These lymphatic vesicles have been long known, and observed on the liver, the brain, the ovaria, and the other viscera; but it is lately discovered that they resemble in nature and almost in form the tænia.

This genus differs from tænia in the membranous vesicular expansion, which appears to constitute its whole form, and in which the head is generally concealed. It differs also in its habitation, for it is never found in the intestines, but on the surface of the viscera, on the membranes, and sometimes enveloped in the fat. In every other respect they are the same; and we remark in them four suckers, and in their centre either a corona of fangs or a depression, apparently the mouth of the animal. It is not surprising that its nature has so long been overlooked, since many trials must be made to discover the head, often the only organic part of its system.

Dr. Tyson first discovered hydatids in the livers of sheep; Bartholine observed them in the livers of goats, and Pyerus in hogs. To Pallas, however, we are indebted for the first correct and connected account of these animals, which he has described and figured in his *Miscellanea Zoologica*. Since the period of his publication, Goëze, Batsch, Bloch, and others, have added to the stock of facts, though much remains to be known. Mougeot, a young physician, has collected in the form of a thesis, entitled "A Zoological and Medical Essay," what has been hitherto published; to which he has added some new facts, and the treatment necessary in one of the species, viz. the hydatids of the uterus. This essay, unfortunately, we have not been able to obtain. Dr. Adams also has endeavoured, with some success, to show that cancer is owing to the introduction of an animal of this kind. But if cancer is owing to an animal, its structure forms the septa so often described in such ulcers. These are, in fact, the animal, not the residence of its formation.

Hydatids are, in general, superficial; that is, some portion is enveloped in the substance of the liver, for instance, and a part rises above it. Yet this is not an universal rule; for, as they are very numerous, some must be wholly concealed. Those species which burrow in the fat are entirely covered, and can never change their place. Their size differs according to the species, the age and temperament of the animal at whose expense they live. Pallas speaks of some as large as the fist, and others are mentioned still more bulky. Such we have ourselves seen. Their figure is infinitely varied, but very generally approaches that of a flattened sphere. Their colour is generally white, or semitransparent, sometimes of an amber colour; their substance composed of different membranes, conglu-

tinated and formed of circular fibres, visible by means of a lens; but in many animals, particularly in sheep, susceptible of an evident contractile power. Internally, on the part opposite to the head, we can observe a disc, somewhat thicker than the membrane, with often a number of fatty tubercles, which have been supposed eggs. They are filled, though not wholly, with lymph, usually transparent, of an oily, salt taste, which becomes cloudy by heat. These vesicles have a motion of their own, which may be styled peristaltic, and is often very lively. The head is not always at the termination, but often concealed by the reduplication of its skin; and from this part the hydatid acts on the viscus in which it lives, and sucks its lymph. The animal is best seen by separating the vesicle, and placing it between two panes of glass, taking care that they press very gently on the anterior part. The head, in that case, pressed forward by the lymph, projects; and even with a lens, the suckers and fangs, if it has any, are observable. This part may be preserved dry for a considerable time.

Hydatids, in the human race, are found chiefly in the liver, the spleen, the uterus, the ovaria, the kidneys, the placenta, the lungs, and even the muscles. Those in the accumulated fluid of dropsies are accused as the cause of the disease; and those in the head are supposed to occasion insanity. Hydatids exist occasionally in the human viscera, without occasioning any inconvenience; but acute pains, either continual or temporary, are supposed to be sometimes owing to them. Their existence may, it is said, be suspected by weakness, emaciation, and oppression at the stomach; but these symptoms are owing to many other causes, and were the existence of hydatids ascertained, there is, we fear, no remedy that would reach them. Hydatids of the liver are often found in a cyst of a cartilaginous firmness, composed of different laminæ, and thicker, in some instances, than in others. The laminæ are white, and apparently lined with coagulable lymph. In one body, Dr. Baillie saw the cyst divided by a pulpy substance. A cyst often contains various hydatids, some floating loosely in the fluid, and some attached to its sides; of very different sizes, from a pin's head to that of a walnut. The largest are generally found floating in the cavity of the abdomen when distended by dropsy.

In animals they are more common than in man. They are generally found in the livers of hares, especially those which have fed in marshy ground. In rats they are equally numerous; and in sheep they occasion vertigo when in the brain, and the rot when they burrow in the liver. In the hog they produce the appearance sometimes called measles; and they are found also in the rein-deer, the goat, and the ox. The remedy in sheep is to change the pasture from the marshes, where the disease is caught, to high gravelly soil, where it seldom appears, and to give the animal a portion of salt; for in salt marshes the hydatids are not found. An author whom we have mentioned, but whose work we have not seen, recommends, we are told, injections of salt water into the uterus when hydatids exist in that organ.

The hydatids of hogs are found in the substance of the fat and in the muscles. They are sometimes so numerous as to be almost contiguous. The disease,

besides measles, is sometimes called lepra; and on this account it seems to have been forbidden to the Jews, among whom the lepra was an endemic disease. The hydatids of hogs are most commonly lodged under the tongue; and, from inspection of that part, the probability of their existence in the flesh may be ascertained.

It has been doubted whether the hydatid of the human body is really a living animal, since its head has not been observed, and no motion is perceivable in it. We, must however, reflect, that the human body is seldom dissected soon after death; and that hydatids, whose heads are not naturally observable, may, by the management already described, be compelled to exhibit them. The hydatid of man is apparently more simple than that of sheep, but its general similarity is so striking that the analogy may be safely transferred; and who shall limit the simplicity of structure consistent with animation? The subject is yet in its infancy, and this must be our apology for the extent of the present article. There are eighteen species described, the more important of which we shall describe.

1. The *globular hydatid* is cylindrical, terminated by a globular, very large, vesicle, found on the liver, the spleen, and other viscera of man. It is the largest species yet discovered.

2. The *visceral hydatid* is globular. Its vesicle is large anteriorly, and pointed posteriorly; it is described and figured by Goëze, found in the liver, the uterus, and the hydropic sacs of the human race; and probably a more frequent cause of dropsy than pathologists have suspected. The vesicles are often lined with an opaque, pulpy coat, but are more usually transparent. It is said that they are frequently contained in each other. This, however, we believe is not true; but we have seen numerous hydatids contained in a sac compressed, without any containing fluid, and apparently without life. When in the ovaria, their most frequent residence, they sometimes appear to occasion a false pregnancy. Treutler has described and figured, in a separate treatise, a visceral hydatid, which, instead of a head, had a small tubercle not retractile. The author thinks, with some reason, that many distinct species have been confounded under this title.

3. The *cellular hydatid* is contained in a cartilaginous vesicle, which has two appendices on its posterior part. It is described and engraved by Werner in an excellent work on the vermes intestinales. It is found in the integuments of the muscles of the human race, and has been supposed to be the same species with that which infests hogs.

4. The *hydatid hydatid* has an elongated body, large anteriorly, with a small vesicle, and a sessile head. It is found in the livers of rats.

5. The *vervecine hydatid* has a large vesicle, with a short body, rough, with an imbricated appearance, and found in the peritonæum of sheep.

6. The *cerebral hydatid* is furnished with retractile tubercles, but has no visible vesicle. It is the animal which causes vertigo in sheep; and, by some naturalists, has been supposed to occasion mania in man.

7. The *hydatid of the hog* is conical, inclosed in a double sac, the interior of which adheres by its base. It has lately been removed to another genus, under the name of *finna*. Werner and his editor; Fischer, represent little pedunculated globules in the room of the

corona of fangs; but Bosc, from frequent examination, asserts that he has always found the latter in this animal.

Three species are found in the viscera of the hare; three in those of a sheep, one in the ox, and one in the dolphin, which are not accurately distinguished. The granulated hydatid figured in Goëze, found in the liver of a sheep, is separated by Rudolph to a different genus, *echinocoqus*.

We must add, that Treutler has published, at Leipsic, a dissertation on many intestinal worms found in the human body, among which he has described a new species of hydatid (*tænia alba punctato*), found in the plexus choroides of a man who died in an idiotic state. The individuals of this species, instead of being inclosed like those of the cerebral hydatid in a common sac, are united by their base through the medium of a membrane. Their form is globular; the largest about half an inch, the smallest $\frac{1}{12}$ in diameter; their colour grey, spotted with black, with six fangs on their heads.

The more important part of the work remains, viz. to point out the means of removing the diseases by destroying the animal which has produced them. But this part of the task naturalists have overlooked; and, in general, hydatids lie out of the course of the circulation, so that little expectation can be formed of the success of any medicine. Mougéot may have given us some information on this subject; but the only hint we can collect from those who have quoted his work is, the injection of a solution of common salt into the uterus, when the hydatids are known to exist in that viscus, from some being occasionally discharged. The circumstance of sheep being relieved, when placed in salt marshes, may suggest the use of common salt; but we must recollect that, in this case, the animal is generally diseased from a known cause, and that in case of plants, the insects which accompany or cause the complaint may be removed by restoring the health and strength. If we apply this to the human body we shall discover an excess of saline nourishment itself a cause of disease; and the prudent physician, who would pursue the hint, will probably find it necessary to be cautious how far in pursuit of a remedy for one disease he may produce a worse. There may be some reason to suspect, that, when alkalis have relieved dropsies, and more certainly when mercurials have had a similar effect, they may have destroyed these animals which are, we fear, often an unsuspected cause of this disease. One other remedy we would suggest, viz. the sulphurated ammonia. We know that sulphur penetrates very minutely into every vessel of the system: we know that sulphurated hydrogenous waters are useful in cases of tænia, and it is highly probable that this may prove a valuable remedy in diseases which arise from hydatids; that it has really proved such, where the cause was unknown. Whatever may be the result, we have, at least, reason to think that medicines of this kind will not injure the constitution which they are given to relieve.

munications, vol. i. p. 101.; London Medical Journal, vol. i. p. 125; vol. vi. p. 159.

HYDATOIDES, (from ὑδαῖος, the genitive case of ὕδωρ, *water*, and εἶδος, *a shape*.) **WATERY**; an epithet for wine much diluted; for limpid urine; for the aqueous humour of the eye; and for the fluid of anasarca.

HY'DEROS, (from ὑδωρ, *water*.) See **HYDROPS** and **ANASARCA**.

HYDRAGO'GOS, (from ὑδωρ, *water*, and ἀγω, *to bring away*.) *Hydroticus*; *aquiducus*. **HYDRAGOGŒ**. Medicines that evacuate much water. In Hippocrates, Epidem. lib. vi. it imports a person affected with dropsy from drinking water.

HYDRA'RGYRUM, **HYDRA'RGYRUS**, (from ὑδωρ, *water*, and ἀργυρος, *silver*; from its having the appearance of fluid silver.) **QUICKSILVER**. This term the college of physicians of London have adopted for the argentum vivum, in their Pharmacopœia of 1788, and use it for the word mercurius in all the preparations of which this metal forms a part. See **ARGENTUM VIVUM**.

HYDRELÆ'UM, (from ὑδωρ, *aqua*, and ελαιον, *oleum*.) A mixture of oil and water. Oribasius and P. Ægineta.

HYDRENTEROCE'LE, (from ὑδωρ, *water*, ἐντέρον, *an intestine*, and κηλη, *a tumour*.) A dropsy of the scrotum. Vogel describes this disorder as compounded of a dropsy and hernia.

HYDRO'A, (from ὑδωρ, *water*.) See **BOA** and **PHLYCTIS**. It sometimes means a pustule called *alhasef* and *asef*.

HYDROCA'RDIA, (from ὑδωρ, and καρδία, *the heart*.) Hildanus invented this word to signify a serous, sanious, or purulent tumour of the pericardium.

HYDROCE'LE, (from ὑδωρ, *water*, and κηλη, *a tumour*.) This term is employed when water is contained in ruptures; but particularly is applied to a dropsy in the scrotum; *hydrofis testis*, *hernia aquosa*, *oscheocele*, and *oscheophyma*. By oscheocele Vogel means a rupture which descends into the scrotum; Dr. Cullen places this genus in the class *cachexiæ*, and order *intumescentiæ*, which he defines a soft, fluctuating, pellucid tumour of the scrotum, not painful.

There are two kinds: in the first the water is lodged in the cells of the membrana cellularis scroti; and it is a symptom of anasarca. The second, and only proper species, is formed by water lodged within the tunica vaginalis of the testicle. The first tumour retains the impression of the finger, the second is elastic.

The second, our only object at present, is a morbid accumulation of the water separated on the internal surface of the tunica vaginalis, to moisten or lubricate the testicle.

From its first appearance it seldom disappears or diminishes, but generally continues to increase, sometimes rapidly, at others more slowly. In some it grows to a painful degree of distention in a few months; in others it continues many years, with little disturbance. As it enlarges it becomes more tense, and is sometimes transparent; so that if a candle is held on the opposite side, a degree of light is perceived through the whole bulk of the tumour; but the only certain distinction is the fluctuation, which is not found when the disease is

a hernia of the omentum or intestines, or an inflammatory or a scirrhus tumour of the testicle.

If the water is lodged only in the cellular membrane, scarifications may be made in the legs, as in an anasarca; but if it is a proper hydrocele, and occasioned by no other disorder, a lancet, or the trochar, may be employed to discharge the fluid; and as the testicle lies always on the posterior part of the tumour, the perforation must be made into the anterior and lower part of it. This is, however, only a palliative remedy.

Mr. Bell proposes the use of a flat trochar in preference to a lancet. The patient being seated, the operator, with his left hand, should grasp the tumour on its back part, so as to push the contained fluid into the anterior and under part of the swelling. An opening must then be made through the skin and cellular membrane, about half an inch long, with a lancet; the trochar introduced through the tunica vaginalis, and the stilette withdrawn, that the water may be discharged. After this the canula may be also withdrawn, and a piece of adhesive plaster should be applied to the orifice. A compress of soft linen may cover the scrotum, and the whole may be firmly supported by a T bandage.

Mr. Pott proposes a radical cure, by exciting an artificial inflammation in the tunica albuginea, and the tunica vaginalis, by means of a seton, which will produce an obliteration of the cavity, in consequence of the inflammation. Mr. Else prefers the application of a caustic (see **CAUSTICUM OPIATUM**) to the fore and lower part of the scrotum; and Mr. Bell recommends an incision into the upper and fore part of the scrotum, to be directed downwards. We shall add a general account of these three methods, referring to the works of the respective authors for further particulars.

Mr. Pott's method, by a seton.—The object of this is to excite the necessary degree of inflammation, if possible, without producing slough or abscess, the hazard of a gangrene, or that alarming degree of symptomatic fever which sometimes attends both the caustic and the incision. The seton requires confinement to bed only for a few days, after which the patient may lie upon a couch to the end, which will be in about a month; and during the whole time the common remedies of inflammation are only necessary. The manner of performing it is as follows:—"Choose a time when the vaginal coat is moderately distended; and having pierced it with a trochar of a tolerable size, draw off the water; when that is done, introduce into the canula a probe armed with a seton, consisting of ten or twelve strings or threads of silk; pass the probe as high to the upper part of the vaginal coat as you can, and on the end of that probe make an incision of such a size as to enable you to pull it out easily, together with a part of its annexed seton; then cut off the probe, and tie the silk very loosely, covering the orifices with pledgets. By the next day the seton will be found to have contracted such an adhesion to the tunica albuginea as would cause a great deal of pain to detach; but this it is perfectly unnecessary to do, and it should be suffered to remain without molestation. In about forty-eight hours the scrotum and testicle begin to swell and inflame; the patient should then lose a little blood, and have a stool or two, and the whole tumefied part should be

wrapped in a soft poultice and suspended in a bag truss. The disease from this time bears the appearance of a large hernia humoralis, and must be treated in the same manner, by fomentations, cataplasms, &c. The adhesion of the seton to the albuginea generally continues firm, and I never meddle with or move it till it becomes perfectly loose, which it seldom does for the first fortnight, or until the inflammation is going, and the humours subsiding. By the time the seton becomes loose, the coalition of parts is universally and firmly accomplished. I then withdraw it, and heal the orifices with a superficial pledget."

Mr. Else's method, by a caustic.—"My method is this:—to lay a small caustic upon the anterior, inferior part of the scrotum, taking care to avoid the testicle: a large caustic is quite unnecessary, and every advantage may be derived from one whose eschar will be no bigger than a shilling. The loose and pendulous situation of the scrotum renders the application of a bandage so very inconvenient, that we cannot easily prevent the caustic from spreading somewhat; for this reason, I cover no more than the size of a sixpence, on a presumption that it may make an eschar as broad as a shilling, though it commonly makes one of the size of a half crown. The intention is, that it shall affect, and, if possible, penetrate through the tunica vaginalis; so that the time it is suffered to lie on is proportioned to the supposed thickness of the cyst. The caustic should never remain on less than five hours; but if it be suffered twenty-four hours, it can do no mischief when properly guarded. On the removal of the caustic, digestives may be applied to the eschar, or the common cataplasm of white bread and milk. The scrotum must be suspended in a bag truss; and the patient had best be confined to his bed, though even this circumstance is sometimes omitted without detriment. Sometimes, immediately after removing the caustic, at other times within twelve or twenty-four hours, or even at the distance of two or three days, the patient begins to complain of a pain in the scrotum and loins, has now and then some colic pains, and the pulse a little quickened, and the tongue whitish. At different periods of time, from the removal of the caustic, but generally within forty-eight hours, an alteration is perceptible in the scrotum; the tumour, upon grasping, feels more tense and hard than it was before, and this hardness answers to the figure of the tunica vaginalis in its whole extent; and a little attention will convince an observer, that it is this membrane alone which gives the sensation of tension and hardness, and no other part. The colic pains and febricula seldom continue more than twenty-four or forty-eight hours; and very frequently are so inconsiderable as to require neither evacuation nor any internal medicines. If, however, the pulse be quickened a little, the pain of the back and the colic distressing to the patient, they will be speedily removed by one or two bleedings, and the injecting one or two clysters. As soon as the pain of the back (except what arises from the weight of the scrotum), the febrile heat, and other symptoms are removed, for they commonly go off altogether, the patient need no longer be confined to his bed, but may be suffered to get up and walk about the room, provided the scrotum be suspended. In a few days the eschar of the scrotum

will loosen and come away, exposing to view the tunica vaginalis, which bears evident marks of its having been affected by the caustic, and prepared to slough off; and when pressed with the finger, the undulation of the water may be felt within it. As the cure proceeds, the sloughy tunica vaginalis will project more and more through the orifice of the scrotum; and when it appears ready to burst, it may be punctured with a lancet, and for this reason only, that it will relieve the patient from the weight of the tumour; for no other advantage can be derived from it. If the water is discharged by a puncture, the scrotum by degrees collapses, and the orifice in it is filled up with slough, which prevents the access of external air to the testicle. These sloughs continue to come away with the dressings daily for about four, five, or six weeks; and in proportion to their discharge, the hard tumour of the scrotum lessens. Upon casting off the last slough, the hardness is entirely gone, the wound immediately cicatrizes; and the cicatrix being about the size of a finger's end, adheres strongly to the body of the testis, which has never come in sight, nor has had any application brought in contact with it during the whole process."

Mr. Bell's method, by incision.—"The patient being placed upon a table of a convenient height, and being properly secured by two assistants, with the scrotum lying nearly upon the edge of the table, the operator with one hand should grasp the tumour so as to hold it firm, and make it somewhat tense on its anterior part; and with a common round edged scalpel in the other, he is now to divide the external teguments by one continual incision from the superior extremity of the tumour, all along its anterior surface, down to the most depending point of the swelling. By this means, as the divided scrotum retracts a little, the tunica vaginalis is laid perfectly bare, for the breadth of half an inch, or so, from one extremity to the other. An opening is now to be made with a lancet into the vaginal coat, just at its upper extremity where the first incision commenced. This opening should be of such a size as to receive the operator's finger, which being inserted, the probe pointed bistoury is to be conducted upon it, and by means of it the sac is to be divided to the very bottom, all along the course of the first incision. By making the first opening into the sac at the upper end of the tumour, much trouble and inconvenience are prevented, which making the first orifice below is sure to occasion: for, as we have before remarked, when the tumour is first opened below, the water is instantly evacuated; and as that produces an immediate collapse of the tunica vaginalis, the passage through its cavity is not afterward easily discovered; whereas, by making the first opening above, as the water is thereby evacuated gradually, as the incision is extended downwards, the vaginal coat continues distended to the bottom till the incision is completely finished. The incision being completed in the manner directed, the testicle, covered with its tunica albuginea, comes into full view. Sometimes the testis protrudes from the wound altogether; in which case it must be replaced with great caution, and it ought by all means to be covered as quickly as possible from the external air; and, provided none of the tunica vaginalis is to be removed, this may be always done immediately, by finishing the dressing directly on the

sac being opened. When the sac is not too much thickened, there is no necessity for removing any part of it; but when it is discovered to be otherwise, to be thick and very hard, the removal of a portion of it on each side of the incision makes the cure of the remaining sore more easy and expeditious. As in this hardened state the sac generally separates with great ease from the surrounding teguments, any quantity of it may be easily taken away with the scalpel, without the least hazard of wounding the scrotum." As soon as the incision has been made, Mr. Bell inserts, between the tunica vaginalis and the body of the testis, slips of soft linen, smeared with some simple ointment, which causes much less irritation than dry lint, and is much more easily removed.

Mr. Earle's method, by injection.—Professor Alexander Monro, of Edinburgh, having supplied the hint of curing the hydrocele by inflammation, Dr. Monro, surgeon to lord Hume's regiment, attempted to make a radical cure by letting out the water of a large hydrocele, and injecting a little spirit of wine into the scrotum, which raised a violent and dangerous inflammation. When this was relieved by the usual remedies, he never had any return of the hydrocele. This violent inflammation induced him to try a milder remedy. Having let out the water, he injected some claret into the scrotum, by which means only a slight inflammation was raised; but still succeeded to his wish, by completing a cure. He has since made several radical cures by this remedy alone. See Monro on the Dropsy, p. 165, note (w), London, 1756.

Mr. Earle's method is so similar to this, that it can scarcely be doubted from whence his ideas were derived. If the tumour be very large, it should, he observes, be emptied, and the water afterwards suffered to accumulate till about six ounces are collected. The cyst is then to be tapped in the usual mode, and as much of a mixture of red port wine, with one third of water made blood warm, is to be thrown in through the canula of the trochar as will distend the tumour to its original size. It is to be allowed to remain there for four or five minutes, and then to be pressed out: should the subsequent inflammation prove considerable, a common bread poultice may be applied.

Perhaps neither Dr. Munro nor Mr. Earle can claim the discovery; for the same method has been recommended by M. Lambert above a century ago, in his *Cœuvres Chirurgicales*, published at Marseilles. A strong solution of corrosive sublimate in lime water was the composition of which he made use; and he gave a variety of cases in which success was the consequence.

See Monro, on the Tumours of the Scrotum, in the *Edinburgh Medical Essays*, vol. v.; Pott's *Account of the Method of obtaining a radical Cure of the Hydrocele*; Else, on the *Hydrocele of the Tunica Vaginalis Testis*; Bell's *Surgery*, vol. i. p. 403, &c.; London *Medical Journal*, xi.; White's *Surgery*, p. 328.

HYDROCELE CYSTATÀ resembles the common hydrocele; but the tumour does not extend to the testicle, which may be felt below or behind it, while in the hydrocele of the vaginal coat, when large, the testicle cannot be discovered. In this disease also the penis is not buried in the tumour. Sometimes the fluid is contained in two distinct cells; and this is discovered by little contractions in it. It is distinguished from the

anasarcous hydrocele by a sensible fluctuation, and the want of the inelastic pitting; from hernia, by its beginning below, from its not receding in an horizontal position, and not enlarging by coughing or sneezing. The cure is the same with that of hydrocele of the vaginal coat: in children it is often removed by spirituous applications.

HYDROCELE FUNICULI. An hydrocele of the spermatic chord is usually a symptom of ascites; but is sometimes an anasarca swelling of the surrounding cellular substance. It is owing to the usual causes of dropsy, and occasionally to the pressure of a truss. In an erect position it is oblong; in a recumbent posture flatter, and somewhat round. The swelling is generally confined to the groin, though it sometimes descends to the scrotum, and enlarges it to a considerable size. When a local complaint, the water may be discharged by a trochar or lancet.

HYDROCELE PERITONÆI. See ASCITES.

HYDROCELE SPINALIS. See SPINA BIFIDA.

HYDROCELO'DES ISCHURIA, (from *ὕδωρ*, *aqua*, and *κλῆιδες*, *attended with tumour*). A suppression of urine from a rupture of the urethra opening into the scrotum. See ISCHURIA.

HYDROCEPHALUS, (from *ὕδωρ*, *water*, and *κεφαλή*, *the head*). DROPSY OF THE HEAD. This disease has been divided into two species, external and internal. In the first, water is confined between the skull and the integuments. In the second, the fluid is within the cranium, between it and the brain; between the membranes; or distending the ventricles. Dr. Cullen places the hydrocephalus externus, including those cases where the fluid is between the skull and the dura mater, as a genus in the class *cachexiæ*, and order *intumescentiæ*, which he defines a soft, inelastic, intumescence of the head, with the sutures of the cranium gaping. This complaint is so obvious, that it requires not any description for its discovery. In general, it is necessary to establish some drain from the head by a continued blister from the neck; free copious evacuations by stool must be procured; and we think the cure expedited by a grain of calomel every night. This medicine seems to give tone and energy to the circulation, which, in this disease, is apparently deficient. With the same view, after the vessels of the head are emptied, the bark, with cold bathing, is highly useful; and even when the head has been peculiarly large this plan has succeeded. See *London Medical Observations*, vol. v. p. 13; *Medical Transactions*, vol. ii. p. 18; *Edinburgh Medical Essays*, vol. ii. p. 22.

The hydrocephalus internus is placed as a species of apoplexia hydrocephalica in Dr. Cullen's system. In a nosological work, he remarks, it is difficult to arrange accurately diseases which assume in their course different appearances; but he prefers placing this disease under the title apoplexy, because the tumour is not evident to the senses; and because it greatly differs in its symptoms from the external hydrocephalus, which is clearly perceptible. In its proximate cause, also, and at length in its symptoms, it is nearly allied to apoplexy. Dr. Fothergill names the internal hydrocephalus the dropsy of the ventricles of the brain, for the ventricles are the proper seat of the disease. Dr. Macbride names it the febris hydrocephalica; others cataphora hydrocephalica.

The internal hydrocephalus arises gradually, affecting

chiefly infants of a fair light complexion from the early months to about the age of ten. Between seven and ten the disease is rare. The first symptoms are irregular fever, with symptoms of considerable irritation of the bowels, so as to induce a suspicion of worms. The discharges from the bowels are procured with difficulty; the urine is often scanty. In general an obstinate costiveness gives the first symptoms of alarm; but the complaint still proceeds so insidiously, that the most cautious observer can scarcely fix on any appearance to justify alarming the parents. Sometimes slight wandering pains about the nape of the neck or the upper extremities precede, and are considered as febrile. When the disease appears in a more pointed form, a violent pain, deep seated in the head, seems to extend from temple to temple, and across the forehead; sickness is at times considerable; the patient occasionally doses and sighs; the breathing is interrupted; the pulse unusually slow, often irregular; at times the sleep is apparently sweet and easy, but in general disturbed, and interrupted occasionally by a violent scream, often a pathognomonic symptom of the disease. The pupil of the eye is dilated, and scarcely contracts, even by a strong light. The eye itself is often turned upward; but more commonly contracted by a spasm, which occasions squinting. A little before death's approach, feverishness sometimes attends, especially towards evening; at last the pulse quickens, the breathing is very laborious and difficult; the heat excessive; the patient is averse to the light, takes things greedily, and cannot bear any but an horizontal posture; the excrements are insensibly voided; the hands are commonly kept about the head; the eye lids become paralytic, and the iris immovable; a great heat and sweat spread all over the body; the pulse trembles, and strength soon fails, if a sudden convulsion does not bring on the catastrophe.

Many of these symptoms are common to worms, teething, and other causes irritating by sympathy the brain, so that it is difficult to fix upon any which particularly characterize the disease. In general, in the early stages, the costiveness, with marks of irritation in the bowels, are the first appearances which lead to a suspicion; but the screaming, the slow pulse, and the squinting, are the only pathognomonic symptoms. The pulse sometimes sinks to forty in a minute.

There is a spurious kind of hydrocephalus, similar to the spina bifida. It appears on the lower part of the occiput like a bladder of water, and underneath the bone is deficient. Opening it would be as fatal as the opening the tumour of the spina bifida.

The disease both in its pathology and cure is still defective. The more obvious cause on dissection is an accumulation of water in the ventricles, generally attended with considerable fulness of the vessels; but the quantity of fluid is by no means in proportion to the violence of the symptoms; and in many instances where there is no considerable degree of compression from the accumulated water, the worst consequences often follow. These circumstances have led practitioners to suppose, with great reason, that the dropsy is only the effect of a previous disease of the brain; and those, who have brought this opinion into any distinct shape, have thought it to be inflammatory, or an apoplectic fulness of the vessels. The author who supposes it to

be inflammatory is Dr. Rush of Philadelphia, and he thinks early and active bleeding a certain remedy. In this idea, he was preceded by Dr. Quin of Dublin, and has been followed by Dr. Garnett; though these authors have not been equally confident of the success of the remedy. It is necessary therefore to examine the subject more closely.

There is little doubt but that a diseased state of the brain exists previous to the accumulation of the water, and the great question is respecting the nature of this state. We have little reason to suppose it inflammatory, for the disease does not attack strong, healthy children, those over fed, or rendered plethoric by too great care. If there are any children peculiarly subject to hydrocephalus, it is the weak, the pale, and the debilitated. These indeed may suffer from venous plethora; but we ought to reflect that this is not a disease of their time of life. An accumulation of blood in the arteries, in a degree greater than the veins can carry off; veins, as we have seen, tortuous, and in which the motion of the blood is peculiarly slow, may occasion increased exhalation: but to this may be objected, that the early symptoms are not those of compression but of irritation only, of irritation not in the brain, but in the bowels. If we pursue the series of symptoms, we shall find that the consequences of compression are combined with those of irritation, but that the former are by no means in proportion to the quantity of fluid found in the ventricles after death. In this argument we lay no stress on the effect of remedies, for we believe all remedies equally ineffectual.

It is indeed probable that symptoms of irritation and compression may be relative to the constitution of the patient; that, as in the former case, a slighter cause may in a very irritable habit produce violent symptoms, so, in a more torpid system, a little degree of compression may produce insensibility or spasm. Yet these views will not lead us far, and very certainly will not assist us in the cure. The first symptoms show, as we have said, irritation in the bowels, which may be readily supposed to originate from an affection of the brain: the second train are the effects of compression, which may be probably accounted for from the accumulation of fluid.

If, however, we apply these views to practice, we shall find their fallacy: the means of relieving irritation or compression are equally useless; and we see no means of accounting for the symptoms, but from supposing an original defect in the organization of some portion of the brain itself,—a cause which will be supported by its being often confined to particular families, and its often affecting the children of the same parents. What this defect is we cannot explain: but we have seen that a free communication between different parts of this organ is peculiarly necessary; and if we suppose this communication interrupted, the usual consequences of increased action will follow. We see this deficiency of communication in the spina bifida; and children live for some time till the necessity of the free circulation of the nervous power is felt. A want of this free circulation in the brain itself may not be so soon experienced as in the nerves which supply the voluntary muscles; and according to the part where the deficiency occurs, the disease may appear sooner or later. This idea is not supported by dissections; but,

in general, if the vessels are found peculiarly turgid, or the ventricles preternaturally filled, anatomists have been contented with the success of their researches.

We rest with more complacency on this opinion, because it explains the want of success which we think has attended every plan. As authors, however, have had their favourite modes of relief, which they have sometimes thought effectual, it is necessary to describe them.

Bleeding, according to the idea of Dr. Rush that the disease is inflammatory, has been practised; but on this subject Dr. Rush is certainly prejudiced. Wherever he finds bleeding useful, he sees inflammation. It has escaped us if his practice has been imitated in this country, so that its success is equivocal. Topical bleeding, either by the cupping glasses or by leeches, under the influence of Dr. Quin and Dr. Garnett's ideas, we have employed with scarcely even temporary advantage. Blistering either on the vertex, the nape of the neck, or behind the ears, has been more useful, but has never effectually removed the complaint. Purging, in all its forms, has only afforded a slight and temporary relief. We have been told of the effects of mercurials, and have employed them actively, so as to raise a ptyalism; or more slowly to give permanent tone, or as purgatives. It has been said that they have succeeded; but we have unfortunately failed, though when a slight ptyalism has been produced, we have found the symptoms in some degree relieved: the fatal event, however, has scarcely been retarded, or retarded only. In one case, where we suspected the source of the previous complaints, we early employed calomel as a purgative. A very slight soreness of the gums ensued, and the disease even came on during the action of the mercury.

Digitalis, doricum, and cicuta, have been mentioned; but, on examining the accounts of authors who have recommended these remedies, we have found little foundation for their employment, and cannot therefore speak of them from experience. The children subject to the complaint are, we have said, inactive and debilitated; and we should not, *à priori*, expect any considerable advantages from narcotics. As the water is usually contained in the ventricles, an operation is wholly inadmissible.

When we consider the confident assertions of some authors, and compare them with the effects of the most careful trials, we shall find it highly probable that they have mistaken other diseases for hydrocephalus. We have certainly done the same, for we once thought mercurials effectual. In advanced life there are affections of the head not strikingly apoplectic, though similar to apoplexy, which require large doses of mercury, and are relieved by it.

See Whytt on Hydrocephalus; Quin on the Apoplexia Hydrocephalica; Fothergill and Watson, London Medical Observations and Enquiries, vol. iv. and vi.; Withering on the Digitalis Purpurea; London Medical Transactions, vol. ii.; Monro's Observations on the Structure of the Nerves; Edinburgh Medical Commentaries, vol. v. vii. viii.; Medical Communications, vol. i. p. 404; London Medical Journal, vol. i. p. 357; Memoirs of the Medical Society of London, vol. i. p. 165 and 169.

HYDROCI'STIS, (from ὑδωρ, *aqua*, and κιστῆς, a

bladder). ENCYSTED DROPSY, OR DROPSY OF A PARTICULAR PART.

HYDROCERATOPHYLLON, (from ὑδωρ, *water*, κέρας, a horn, and φύλλον, a leaf). See CERATOPHYLLUM.

HYDROGA'RON, (from ὑδωρ, and γαρν, *pickle*). Garum diluted with water.

HYDROGE'NIUM, (from ὑδωρ, *water*, and γίνομαι, *to become*, or γίναω, *to produce*.) HYDROGEN is one of the constituent parts of water, and perhaps of muriatic acid. (See AER, and CHEMIA.) Though its gas is unfit for respiration, it is not poisonous. Its effects on the animal economy are not peculiarly striking, but it appears to affect the irritability of the muscular fibre in a considerable degree; and animals killed by it are supposed to putrefy quickly. The latter opinion seems, however, from Chaptal's Experiments, to be founded on a mistaken observation.

HYDROLA'PATHUM, (from ὑδωρ, and λαπάθον, *dock*). See LAPATHUM AQUATICUM.

HYDROME'LI, (from ὑδωρ, and μέλι, *honey*). HYDROMEL; *mulsum*, *aqua mulsa*, *melicratum*, *braggat*. Water impregnated with honey. After it is fermented, it is called vinous hydromel, or mead.

HYDROME'LON, (from ὑδωρ, and μέλον, *an apple*). Is made of one part honey, impregnated with quinces, and two parts of boiled water, set in the sun during the dog days.

HYDROME'TRA, (from ὑδωρ, *aqua*, and μήτρα, *matrix*). DROPSY OF THE WOMB. See HYDROPS UTERI.

HYDRO'MPHALUS, (from ὑδωρ, *water*, and ομφαλός, a navel). A TUMOUR OF THE NAVEL, containing water. See HYDROPS UMBILICALIS.

HYDRONO'SOS, (from ὑδωρ, *water*, and νόσος, a disease). See SUDOR ANGLICUS.

HYDROPE'GE, (from ὑδωρ, and πηγὴ, a fountain). SPRING WATER

HYDROPEDE'SIS, (from ὑδωρ, and πέδω, *to break out*). See EPIDROPSIS.

HYDROPHO'BIA, (from ὑδωρ, *water*, and φοβία, *to fear*). A DREAD OF WATER; *aquæ ferror*, is a symptom of the disease caused by the bite of a mad animal; but not peculiar to this disease, nor always attendant on it. (See DYSCAPATOTIA.) The disorder has usually had the same appellation, and is called also *canina rabies*, *cynanthropia*, *cynolesia*. Dr. James observes, that this kind of madness properly belongs to the canine genus, viz. dogs, foxes, and wolves, to whom only it seems innate and natural; scarcely ever appearing in other animals, except communicated from these. Dr. Heysham defines it to be an aversion and horror at liquids, as exciting a painful convulsion of the pharynx, occurring at an indetermined period, after the canine virus has been received into the system.

The hydrophobia is a nervous disorder, though attended with some appearances of inflammation. Dr. Cullen places it in the class *neuroses*, and order *spasmi*, defines it a loathing and great dread of drinking any liquids, from their creating a painful convulsion of the pharynx, occasioned most commonly by the bite of a mad animal. This definition, however, scarcely includes the full idea of the disease; and we would suggest the following as more complete: melancholy, a dread of

cold air, of any thing shining, and particularly of water, often arising from the bite of a mad animal. He distinguishes two species.

1. *HYDROPHOBIA RABIOSA*, when there is a desire of biting, from being bitten by a mad animal.

2. *HYDROPHOBIA SIMPLEX*, without rabies, or a desire of biting.

The principal and original seat seems to be about the stomach, and parts contiguous to it. Dr. Seleg thinks that it is seated in the par vagum and intercostal nerves; for most of the symptoms happen where these nerves are interspersed.

The smallest quantity of the saliva of a mad dog produces the disease. The infection may lie dormant for a period, differing according to the habit of the patient, the time of the year, the degree of the disease in the animal, or the place in which the wound is made. If the patient is not of a strong inflammatory habit, and no circumstances intervene, which otherwise affect his health, it seldom takes effect till after about forty days: if in six weeks, or two months, no sign of disorder appears, the patient is usually concluded to be safe. It has been observed, that the nearer the place bitten is to the head, the sooner the symptoms appear. If the part bitten is covered with woollen or leather, the bite is harmless. The dread of water is a symptom in some fevers, and in some particular inflammations (Edinburgh Medical Commentaries, vol. xi. p. 331); and it is highly probable, that in those cases where the poison is said to lie dormant for six or nine months, or even a year, the disease was connected with fever rather than the rabid poison.

When a dog is affected with madness, he becomes dull, solitary, and endeavours to hide himself, seldom barking, but making a murmuring noise, and refusing all kinds of meat and drink. He flies at strangers; but, in this stage, he remembers and respects his master: his ears and head hang down; he walks as if overpowered with sleep; and a bite at this period, though dangerous, seldom conveys the disease. After these symptoms, the dog begins to pant; he breathes quick and heavy; hangs out his tongue to discharge a great quantity of froth from his mouth, which he keeps perpetually open; sometimes he walks slowly, as if half asleep, and then suddenly runs, but not always directly forward: at length he forgets his master; his eyes look dispirited, dull, full of tears, and red; his bark is hollow and hoarse; his tongue of a lead colour; he grows faint, thin, and weak, often falls down, again rises, attempts to fly at every thing, and soon grows furious: this second stage seldom continues thirty hours, death by that time putting an end to the disease, and a bite received at this time is the most dangerous.

When the human species are the subjects of this disorder, a slight pain in the wound is first felt, sometimes attended with itching, but usually resembling a rheumatic pain: it extends into the neighbouring parts, and the cicatrix begins to swell, inflames, and at length discharges an ichor; this pain is considered as the primary invariable mark of a beginning hydrophobia. There are more general pains, of a flying, convulsive kind, which are said to affect the patient in the neck, joints, and other parts; often a dull pain seizes the head, neck, breast, belly, and along the back bone: towards

the conclusion of the disorder the patient complains of this pain shooting from the arm towards the breast and region of the heart. A lassitude, a dull pain in the head, and a vertigo, soon come on: the patient is melancholy, mutters, is forgetful, and drowsy; his mind seems disordered; his temper irritable and irregular; his slumbers disturbed, and convulsive agitations immediately follow his waking; a deafness is sometimes complained of; the eyes are watery; the aspect sorrowful; the face pale and contracted; sweat breaks out upon the temples; an unusual discharge of saliva flows from the mouth, though the fauces are dry; the tongue becomes foul, and the breath occasionally fetid. The fetor is often only perceived by the patient; and sometimes it attends the discharge from the wound, the dressings of which are said to be frequently black. Besides these, from the beginning, there are a peculiar stricture and heaviness on the breast, a struggling as it were for breath, a sighing, a nausea, and often a bilious vomiting. This oppression of the precordia is one of the constant symptoms of this disorder; it begins, increases, and ends with it. As the above symptoms increase, the second stage advances; a fever comes on, which at first is mild, and attended with momentary horrors, though there is sometimes no fever; sleep is lost, the mind is more and more disturbed, a delirium approaches, and an aversion at first to polished bodies, then to light, afterwards to fluids, is perceived. The air offends if it touches the skin, and the slightest sound is very painful. A constriction of the gullet, with difficulty of swallowing, first occurs; but as yet liquids are freely taken; afterwards, however, they are refused. This symptom augments so visibly, that on the sight of any liquid a horror seizes the patient; and if he strives to drink, spasms, anxiety, and loss of sense, follow. As soon as the surface of the liquid is touched, a strangulation in the throat is felt; the stomach is inflated: the larynx is suddenly swelled externally, though the swelling quickly disappears. While liquids are thus rejected, solids are swallowed with tolerable ease; yet this symptom may become so violent as totally to prevent solids also from being swallowed. The patient now mourns bitterly; at times loses all knowledge of his intimate acquaintance; but reason returns at intervals, and he laments his own calamity: the thirst excites a desire of drink, but he strives in vain to swallow, and soon sinks into the most affecting despondency; he advises his friends to keep at a distance, and it is supposed that he feels an inclination to bite; but this is suspicion only, and it is highly improbable that, with the disease of a dog, he should adopt his manners: biting is the common method by which that animal shows his resentment. The barking like a dog is equally imaginary. A priapism and involuntary emissions of semen and urine sometimes attend this stage; and as the conclusion approaches, the fever and thirst increase; the eyes are bright and furious; the urine is high coloured, acrid, and in small quantities; the tongue hangs out; the mouth foams; the pulse throbs, strength fails, cold sweats come on, the tightness of the breath increases, and the patient soon expires in spasms, often losing the difficulty of swallowing liquids, for many hours; so that the dread of water is by no means a pathognomonic symptom.

On dissection, the brain, the medulla oblongata, and all the muscles, are said to be drier than usual: the membranes extenuated; the pericardium dry; the blood coagulates slowly, if at all; and putrefaction soon comes on. The fat appears completely wasted: the gall bladder full of greenish bile; and the stomach covered with a glary matter of a brown colour, and its villous coat livid. The liver, contiguous to the stomach, is livid, and the trachea and œsophagus inflamed.

The poison of rabid animals is, like that of the small pox, secondary in its operation. It lies concealed till, perhaps, by an assimilatory process, its quantity is increased, or from the heat of the body it becomes more active. It is sufficiently certain, that, if the part is extirpated soon after the bite, the patient is safe: it is highly probable that the same operation at the first commencement of the inflammation would be equally advantageous. When absorbed, like other poisons it is carried to some excretory; and that which from chemical affinity or some other cause is preferred, we find to be the salivary and the mucous glands of the fauces. Previous, however, to this determination, it shows deleterious effects on the nervous system by the melancholy, the increased sensibility, and the affection of the precordia, which precede. These are the natural and genuine effects of the poison, which prove sometimes fatal without any others following. Mead.

When the poison is determined to the excretories, it shows a powerful and active stimulus. Inflammation, which is the consequence, in the mouth and fauces, seems to occasion the difficulty of swallowing. The increased sensibility, however has some influence; for if the patient does not see the fluid, or it is not given in a shining vessel, the convulsions are much less violent. The sensation of cold water to the inflamed fauces contributes to the effect. In all these respects, solids will be less offensive than fluids; and in general they are swallowed by a less effort.

The disease in dogs is not owing to heat, but is probably produced by their confinement in kennels. In man the disease is exclusively owing to the poison introduced by the wound; but its action is said to be accelerated, probably increased, by fear, grief, or any of the depressing passions. The prognosis is always unfavourable.

If, in a disease where remedies are so uncertain, we were to draw any prophylactic indications, they would be, first, to prevent the poison from acting, though it exists in the body; secondly, to evacuate it by the most speedy methods.

This disease is peculiarly rare. Some practitioners of the most extensive experience have never seen it; and some have boldly denied its existence. In general, very few of the dogs reputed to be mad are really so; and but a small proportion of those bit by a dog, really mad, receive the infection, as the parts are usually defended by the clothes, and the teeth of the animal are consequently wiped clean before the wound is inflicted. This circumstance has given a delusive credit to many trifling preparations employed as prophylactics. None are to be trusted except excision; but it is necessary to state, according to the indications laid down, what has been proposed.

We have already remarked, that nature is able to evacuate morbid poisons, if the animal power is supported,

or at least no cause of debility gives the poison activity. The first indication is, therefore, answered by avoiding whatever may depress or weaken, and employing every plan to give a tone to the system. The depressing passions are consequently to be counteracted; and should the patient's mind rest on the circumstances of the bite, it should be cheered by every encouraging representation. Perhaps the ridiculous specifics, as eating the liver of the dog broiled, or tying the skin of an hyæna about the arm, may have been useful by inspiring confidence; and avoiding cold and excesses of every kind must be advantageous in every view. Stimulants are useful with the same design; and numerous are the remedies of this kind recommended by the ancients, though condemned by Boerhaave; viz. Galen's theriaca; Scribonius Largus' opiate, a preparation containing opium with large quantities of aromatics; the cibi acres of Dioscorides; the wine of Celsus; the garlic and theriaca of Palmarius and Mayerne, who added occasionally the scordium, the snake root, and the flowers of hypericum; and the pepper of Mead; are of this kind. Tonics have been also employed, the chief of which is cold bathing. The ancients used it with every mode of exciting terror; and when they used the warm bath in this complaint, the patient on coming out of the water was plunged "in piscinam." Other tonics have not been employed, though we find the filings of tin in Mayerne's remedy; and in some formulæ, the varvain, the lesser sage, plantain, and polypody; and in others, the wormwood, mint, betony, hypericum, and lesser centaury—medicines which, if they have any power, must act as tonics.

In following the second indication, we may evacuate the poison from the wound by sucking, by washing it with hot water, by cutting it out, by bleeding with cupping glasses, by enlarging the wound, increasing the discharge with suppurating applications, by burning it with gunpowder, or destroying an absorbing surface by a caustic. Each has been employed, and each has had its partisans; but to cut out the part is the only certain remedy, and it is certain at any period previous to the inflammation. If the wound is inflicted so deep that the bitten part cannot be separated, a caustic must be applied to what remains; and though we thus lessen the chance of relief, we should reflect that, at the depth of the wound, the tooth has already lost its venom. Yet such are the horrid consequences, that even the loss of a limb would, in the event of a violent wound from a dog certainly mad, cheaply purchase security.

When our attention has been paid to the wound, we must look to the other excretories for the evacuation of the poison: those most commonly preferred are the skin, the urinary organs, the salivary or intestinal glands. Mercury given in small doses, and long continued so as very slightly, if at all, to affect the mouth, may be considered as a diaphoretic. Sauvages has collected a variety of cases in which those who took mercury in this way escaped, while others bit by the same animal died hydrophobic. Desault, James, and others, have added their testimony to the success of the same measure; but we must add, with regret, that later experience does not support their decision. It is painful to be obliged so often to oppose positive assertions; but it would be injurious to mankind to support a delusive security. We have already observed that a dog, supposed to be

mad, seldom is so; and that of ten bitten by an animal really mad, not above one or two are infected with the disease. Of the same kind is the famous Chinese remedy, which consists of ten grains of mosch, with twice the quantity of factitious cinnabar, for the dose is ordered to be repeated, if sleep and sweat do not follow; and Hillary has observed that it is useful in proportion as it proves diaphoretic. The warm bath has been highly commended, particularly by Lieutaud; but later experience has not confirmed its utility.

The principal diuretic is cantharides, but they have been seldom employed. The chief authority we can find for their utility is Baccius de Venenis and Antidotis, and some cases in which they appeared to be useful are recorded in the first volume of the Bologna Transactions. The ashes of the river cray fish, burnt by twigs of bryony; the sponge of the dog rose; the alyssum or mad wort; and the lichen cinereus terrestris; have been considered as diuretics. They may be such; but they are useless in this disease.

The cathartics employed in hydrophobia have been the rhubarb, the hiera picra, the colocynth, and hellebore; but we have received no positive accounts of their utility, and have reason to think them of little importance.

It has been supposed that the organs may be sheathed with oil, and absorption prevented, or the acrimony of the poison covered. This plan too has flattered and disappointed practitioners; and the Ormskirk medicine, which is principally an antacid, has had no better success.

When the disease has come on, it has been the object of practitioners to sooth the early symptoms of irritation by opium, or to assist the natural discharge by the more active exhibition of mercurials. Dr. Rush, in his reveries respecting inflammation, thought this disease also inflammatory, and proposed active bleeding. We can trace this remedy in the History of the Academy of Sciences at Paris for the year 1699, p. 58, recommended by Poupert; and we find it also mentioned in the Medical Essays of Edinburgh, vol. v. part ii. § 51. This also has failed. Later authors have called hydrophobia a putrid fever, and given bark in large quantities, but with the same success.

Opium seems to rest on more rational principles, and two grains, or even a larger dose, given every three hours, seem to have relieved the symptoms, but have done no more. A ptyalism, rapidly excited, and steadily continued, has scarcely succeeded better; and the vinegar, of which four ounces have been directed three times a day, has equally failed. *In short, full, effectual, and COMPLETE EXCISION of the wounded part is the only certain means of relief; AND THIS IS CERTAIN.*

See *Ætius, Cœlius Aurelianus, Lommius, Sauvages sur la Rage, Desault; James on Canine Madness; Mead on the Bite of a Mad Dog; Seleg, Nugent, and Hamilton on the Hydrophobia; Medical Museum, vol. ii. p. 97, &c.; London Medical Transactions, vol. ii. and London Medical Observations and Inquiries, vol. iii.; Edinburgh Medical Commentaries, vol. v. p. 42; Vaughan's Two Cases of the Hydrophobia; Cullen's First Lines, vol. iv.; White's Surgery, p. 102; Memoirs of Medical Society of London, vol. i. p. 243; Memoirs of the Royal Society of Medicine in Paris, Supplement to vol. iv.*

The second species arises without any contagion, in some fevers from topical inflammations of the thorax or neighbouring parts; from the accession of an epilepsy; from the bite of an epileptic patient; the bite, it is said, of persons in violent fits of passion: an inferior degree of it will be observable in some hysteric cases, when, from the difficulty of swallowing, patients are fearful of taking liquids, and sometimes cannot be prevailed upon to make the attempt. In all these cases, musk and opium appear to be chiefly efficacious.

HYDROPTHALMIA, (from *ὕδωρ, water*, and *ὀφθαλμος, the eye*). See PROPTOSIS.

HYDROPTHALMION, (from the same). It is the part under the eye which swells in cachectic and hydroptic cases.

HYDROPHYSOLE, (from *ὕδωρ, water, φυσσα, a flatus*, and *κηλη, a hernia*). A HERNIA proceeding from a mixture of water and flatulence.

HYDROPIPER, (from *ὕδωρ*, and *πίπερ*; from its pungency, and growing in marshy places). See PERSICARIA URENS.

HYDROPNEMOSA'RCA, (from *ὕδωρ, water, πνευμα, wind*, and *σαρξ, flesh*), a tumour, from a mixture of flatulent, aqueous, and carneous substances.

HYDROPOIDES, (from *ὕδωρ, water*, and *εἶδος, a resemblance*). Aqueous excretions, common in dropsies.

HYDROPS, (from *ὕδωρ, water*), *hyderos*; a DROPSY. In reality there is but one kind of this disease, for all the various dropsies differ only in their seat. As this circumstance suggests a variety of practice, we have distinctly considered the peculiar circumstances under each head, and shall now add only a few general remarks.

All dropsies are chronical diseases from debilitated fibres; but this debility may be general or particular. It is, however, always attended with an accumulation of serosity, either in the whole of the cellular texture, or in particular cavities. In the anasarca the water is clear and limpid, but in the ascites often more thick and gelatinous, or sometimes mixed with hydatids or coagulated lymph.

Each age and sex is liable to this disorder; but generally it happens to men advanced in years, and to women after child bearing; those who live in low wet situations; whose life is sedentary, and who have indulged in spirituous liquors.

The general or immediate causes of all dropsies are increased exhalation or diminished absorption. The former, in anasarca, is, according to Dr. Hunter, owing to transudation. This, however, makes little difference in the present view of the subject; and it is useless to engage in an examination of the distinction, as it will not apply to any practical improvement.

Increased exhalation often arises from an interruption to the return of the venous blood; and this interruption may arise from diseases of the right ventricle of the heart, or its valves, from an upright posture, when the force of gravity opposes the return; scirrhi, or other obstructions in the liver or spleen; polypous concretions in the veins; aneurisms in the arteries; abscesses; scirrhi or steatomis in the neighbourhood of the arteries or the veins; the gravid uterus, &c.

A general debility and laxity of the whole system are a common cause of increased exhalation, and dropsies

are, in this way, occasioned by repelled eruptions or suppressed evacuations; by general causes of debility, as palsy, long fevers, excessive evacuations, and intemperance.

A preternatural quantity of watery fluids taken into the system, or absorbed by the skin, has been considered as a cause of dropsy; and a preternatural tenuity of the blood from saline acrimony has been said to produce the same effect. Each, however, is, we believe, rare. Nature easily disposes of the superabundant fluids, if the secretions are free; but when suppressed, as in cold watery situations, by an ischuria renalis, &c. dropsy will probably follow.

A rupture of the thoracic duct, of the lacteals or lymphatics of the kidneys, ureters, or vesica urinaria, may produce dropsy; but these causes are peculiarly rare. Hydatids, on the contrary, we suspect to frequently induce this disease.

Absorption may be diminished from loss of tone in the absorbing extremities of the lymphatics, and by obstructions to the passage of the absorbed fluids in their course. See LACTEALS and LYMPHATICS.

These causes of dropsy, though separately stated for the sake of distinction, are frequently combined; and we must confess that the great outline will not admit of practical application. Our chief object is to evacuate the water by increasing the secretions, while we support the general tone of the system by a warm cordial diet, cordial and tonic medicines, which do not possess too great a degree of astringency. The bitters called aperient are, in general, best adapted for this purpose. The general evacuants we have noticed in the articles of ANASARCA and ASCITES, q. v. We shall now add the means of obviating some of the more troublesome symptoms.

Dropsies are not quickly fatal, except when produced by polypus concretions in the heart or pulmonary vessels; a scirrhus liver; tumefied mesenteric glands; a scirrhus or otherwise disordered uterus. Bleeding of the nose, ulcers, or gangrene, appearing in any part, are highly dangerous. Great thirst, the upper parts greatly extenuated, febrile horror with external heat, an erysipelas on the legs, livid streaks or spots on the skin, are among the most dangerous symptoms.

Thirst.—We see no reason for the rigid abstinence so often enjoined: the patient may, in general, drink in proportion to his inclination. Acid liquors, as cyder, or in want of it vinegar imperial, with a small proportion of the spirit of juniper, or rhenish wine and water, may be allowed; and thirst is often prevented by holding nitre in the mouth.

Difficulty of breathing.—In this case the loss of few ounces of blood has been recommended; but though a momentary relief is thus obtained, the injury will be considerable. The safest method is, if possible, to obtain relief by expectoration; and for this purpose a mixture of the gum ammoniac with the acetum scillæ may be repeated as the occasion requires. The infusion of garlic is often useful, and the asafetida relieves the dyspnoea when it is connected, as is often the case, with flatulency in the stomach, occasioning hysteric affections. In this situation also a warm plaster or liniment, with a large proportion of opium, may be applied to the pit of the stomach.

Spasms often arise in particular parts, especially about

the chest, frequently awaking the patient out of a sound refreshing sleep. In such cases opium, with camphor, is the only effectual remedy; and even in hydrothorax, when the dyspnoea is considerable, is often a safe remedy. It is only contraindicated when there is a considerable and apparently necessary discharge from the mucous glands of the bronchiæ.

Vomiting is relieved often by the chalk julep, with a slight warm opiate, or by a saline draught in the act of effervescence.

Purging requires regulation only, for it is often a salutary discharge.

See Hoffmann, Boerhaave, Lister, and Lysons, on this disease; Le Dran's Operations; London Medical Transactions, vol. ii.; Cullen's First Lines, vol. iv.; *Monro on Dropsy.*

HY'DROPS AD NA'TULAM. See DIABETES.

HY'DROPS ARTI'CULI. See HYDROPS GENU.

HY'DROPS CYSTICUS. The ENCYSTED DROPSY is a collection of water enclosed in a cyst, which is sometimes from a collection of hydatids, and generally in the abdomen. See HYDATIS and HYDROPS OVARII. *Le Dran's Observations*, edit. 2. p. 129.

HY'DROPS GE'NU. A DROPSY IN THE KNEE; water collected under the capsular ligament of the knee. *Dr. Hunter* observes, that if the synovia is separated in too large a quantity, and the absorbents fail in their action, an hydrops articuli succeeds, causing relaxation of the ligament. *Mr. Sharp* recommends a tight bandage, leaving the superfluity to be absorbed by the lymphatics. To this might be added some attenuating and discutient embrocation, such as the aq. ammoniæ acetatæ; or a solution of crude sal ammoniac in sharp vinegar: their proportion may be $\frac{3}{4}$ ss. to ℥i. See *Gooch's Cases and Remarks*, vol. ii. p. 259—266; *Edinburgh Medical Commentaries*, vol. vi. p. 132.

HY'DROPS MEDU'LLÆ SPINA'LI. See SPINA BIFIDA.

HY'DROPS OVA'RII. A DROPSY OF THE OVARIUM. This species of encysted dropsy most frequently happens to barren and superannuated, sometimes to pregnant women. It usually begins without pain, and the health is unimpaired. It is not perceived until it is much enlarged, and commonly appears but on one side. It is known by its being moveable when the patient is laid on her back, and by passing the finger up the vagina the orifice of the uterus is found to move with the tumour, which distinguishes it from the ascites. But it seldom happens that the tumour rises above the pelvis, till general dropsy has come on and obliterated the situation of the tumour. In this species, the fluctuation is indistinct, and the disease is generally, and indeed we believe constantly, occasioned by hydatids. When there are several cysts, there are sometimes inequalities in the tumour, and it has the feel of scirrhus. Internal medicines are of little efficacy: tapping may relieve for a time, and the operation is as safe as in the common ascites; but the resistance to the instrument is considerable, for the cyst thickens by pressure. Diuretics, purgatives, and mercurials, are equally inefficacious. *Dr. Percival* gives an instance of a cure being effected by a spontaneous vomiting; see his *Essays, Medical and Experimental*. But to assist the general health of the patient is almost the only means in our power.

HY'DROPS PE'CTORIS, also **HYDROTHO'RAX**. A **DROPSY** in the **BREAST**. Dr. Cullen places it in the class *cachexiæ*, and order *intumescentiæ*; defining it a difficulty of breathing, pallid countenance, œdematous swelling of the feet, difficulty in lying down, a sudden and spontaneous starting out of sleep with palpitation, and water fluctuating in the chest. The water may be on only one or both sides of the mediastinum: it is usually on one side only; but sometimes this fluid is contained in hydatids, whose situation may be on the diaphragm, the pleura, on the external surface of the lungs, in their substance, on the surface of the heart, or in the pericardium. In this case the knowledge of the case and cure are alike uncertain.

Any of the causes of dropsy may produce this species; it sometimes happens from increased exhalation in consequence of a disorder of the lungs, or from an infarction of the bronchial glands, occasioning obstruction to the passage of the blood; often from debility only, seldom from hydatids.

The symptoms, particularly when the water is extravasated on the diaphragm, are an oppression of the precordia, a very irregular pulse, and an extraordinary shortness of breath, sometimes relieved by a supine posture: in this it is distinguished from fits of asthma when the patient cannot lie down. A distinguishing symptom of this disease is, the starting from sleep with a sense of suffocation; and though this may sometimes attend obstructions in the thorax, from other causes, it almost constantly attends every hydrothorax when in a considerable degree. In the dropsy of the breast, also, œdematous swellings are not only observed in the feet but also in the hands, which Baglivi says is a pathognomonic sign; and it certainly is so, when united with a coldness of the hands, and a livid colour of the lips. Inspiration is more easy than expiration; and if there is much water on one side, the face, arm, and leg on that side are sometimes swollen.

Instances have occurred in which the water hath been absorbed; but, for the most part, the patient falls a victim to the disease. As a palliative, when the water is perceived to fluctuate, it may be drawn off by a canula and trochar, introduced betwixt the fourth and fifth of the false ribs, and about four fingers breadth from the spine. The seat of the disease, however, can seldom be so accurately ascertained as to admit of this operation, and we must, in general, rest on the remedies of dropsy. Blisters on the legs will, however, often relieve the complaint by evacuating much water, and drawing it downward. Digitalis is supposed to be a remedy peculiarly adapted to this complaint, and it sometimes appears to be useful in obstructions of the chest from any cause. The ether of Mr. Tickell, which contains a proportion of the oleum vini, is said also to be a very useful remedy; but we have seldom found any particular advantages from it. As an antispasmodic, it may be supposed to relieve what are styled the symptomata ephialtica, the startings from the sleep; but in this respect its efficacy is doubtful, and opium succeeds more certainly and more effectually. When the load of water is partly taken off, this is a safe remedy. Vide **HYDROPS**, **ASCITES**, and **ANASARCA**. See Le Dran's *Operations*, edit. 2. p. 117, 118; Cullen's *First Lines*, vol. iv; Bell's *Surgery*, vol. ii. p. 356.

HY'DROPS PERICA'RDII. **DROPSY** of the **PERICARDIUM**, a superabundance of watery fluid collected within the pericardium. There are no symptoms by which the disease can be certainly discovered in the living body; cases can only be referred to, in some of which the cause has been suspected, in others ascertained, by dissection. In general, there are great oppression and anxiety, a labouring irregular pulse, with the other symptoms of hydrothorax. The treatment does not differ from that of hydroyps pectoris. See Sauvages' *Hydrothorax Pericardii*, Morgagni de *Causis Sedibusque Morborum*, xvi. 34, 36; Senac. de *Cœur*, tom. ii. p. 349; Bouillet, *Dissert.* 1758; *Edinburgh Medical Essays*, vol. v. p. 56, 58, 59.

HY'DROPS PULMONUM. The **DROPSY** of the **LUNGS** is seated in the cellular membranc of the lungs. Sometimes it attacks suddenly, from an hydatid bursting, and filling the cellular membrane.

The diagnostics are very obscure: the difficulty in breathing is constant, and increased by the least motion, though not much varied by different attitudes and situations; the anxiety about the precordia is considerable; and, on attempting a deep inspiration, the patient finds it impossible to dilate his chest, and his breath seems to be suddenly stopped: the pulse is small, languid, and oppressed; the face pale and bloated; the legs swelled, and the whole body leucophlegmatic.

A brisk mercurial cathartic will often give very quick relief. After this, the seneka root, in large doses, will be useful, as it operates powerfully by expectoration, urine, and perspiration. Besides these the usual diuretics and sudorifics may be administered. If the case is desperate, an operation, as in the empyema, may be tried. See *Edinburgh Medical Essays*, vol. vi. p. 126; Percival's *Essays, Medical and Experimental*, p. 172; Bell's *Surgery*, vol. ii. p. 356, &c.

HYDROPS SA'ECULI LACHRYMA'LIS. See **HERNIA LACHRYMALIS**.

HYDROPS SCRO'TI, and **HYDROPS TE'STIS**. See **HYDROCELE**.

HYDROPS UMBILICA'LIS; **UMBILICAL DROPSY**; *exomphalus aqueus Platneri*; *hydromphalus* of Ægineta, Heister, Dionis.

It occurs in pregnant women, from severe labours; infants who labour under ascites and hernia umbilicalis. According to Platner, it scarcely can ever happen without an umbilical rupture and ascites; the tumour is soft, fluctuating, permanent, and pellucid, when examined by the light of a candle. The treatment is that of hydrocele.

HYDROPS U'TERI. **DROPSY** of the **WOMB**, is seated in the cavity of the womb, and the collection of water there is so great, that the belly appears as if affected with an ascites: on pressure, a fluctuation is perceived. It may take place during pregnancy, but is not usually an attendant. Dr. Cullen defines it a tumour of the hypogastric region, slowly and gradually increasing, resembling the figure of the uterus, yielding to, or fluctuating on, pressure; without ischury or pregnancy. From Sauvages he enumerates seven species, which cannot, however, be distinguished by external signs, viz. *Hydrometra ascitica*; *hydrometra gravidarum*; *hydrometra hydatica*; *hydrometra sanguinea*; *hydrometra*

puriformis; *hydrometra ascites uterinus*; and *hydrometra sanguineo-uterinus*.

The diagnostics are not distinct; for many fallacious signs of pregnancy accompany this disorder. It is distinguished from the ascites by its being confined to the region of the uterus, and by the thinness of the os tincæ. If the tumour is from a scirrhus, it is never in the middle, nor is it round, like the dropsy. This disease is soon followed by an anasarca, a slow fever, and a marasmus.

A canula introduced into the uterus is the best and speediest remedy; but sometimes a scirrhus, a cicatrix, or tubercles prevent it. If the canula cannot be introduced, hard riding, violent shocks, with emetics, sternutatories, and brisk cathartics, may be employed.

HYDROPY'RETOS, (from *υδωρ*, *water*, and *πυρετος*, *a fever*). *Sudor Anglicus*. Blanchard.

HYDRORACHI'TIS, (from *υδωρ*, *water*, and *ραχις*, *the spine*). See SPINA BIFIDA.

HYDRORO'SATON, (from *υδωρ*, *water*, and *ροδον*, *a rose*.) a drink made of water, honey, and the juice of roses. See Paulus Ægineta, lib. vii. c. 15.

HYDRORHO'DINON, (from *υδωρ*, *aqua*, and *ροδιον*, *the oil of roses*.) water mixed with the oil of roses; given by Galen as an emetic in cases of poison.

HYDROSA'CCHARUM, (from *υδωρ*, *aqua*, and *σακχαρον*, *sugar*.) a composition of sugar and water, which answers to the hydromeli by changing honey for sugar.

HYDROSA'RCA, (from *υδωρ*, *water*, and *σαρξ*, *flesh*). A tumour or abscess containing water and flesh. M. A. Severinus.

HYDROSARCOCE'LE, (from *υδωρ*, *water*, *σαρξ*, *flesh*, and *κληη*, *an hernia*). See SARCOCELE.

HYDROSELI'NUM, (from *υδωρ*, and *σελινον*, *purslane*). See APIUM.

HYDROTHO'RAX, (from *υδωρ*, and *θοραξ*, *the chest*). See HYDROPS PECTORIS.

HYDRO'TICUS, (from *υδωρ*, *water*). See HYDRACOGUS.

HYGI'DION. A collyrium described by P. Ægineta, lib. vii. c. 16; called *ammonii collyrium*.

HYGI'DION HYGE'IA, HYGI'DION HYGIE'IA, (from *υγιη*, *sound*). HEALTH or SOUNDNESS. The name of a plaster called *panacea*, and the PLASTER of the THREE BROTHERS, described in Ætius. Health, however, a more extensive sense, comprehends a great variety of considerations, which, in the Leyden school, formed a considerable and important part of the institutions of medicine. We cannot attend to it with equal care; and indeed its doctrines comprehend a variety of subjects treated of under distinct heads. We must not, however, pass it over lightly.

It will be at once obvious that health is a relative term; for the changes consistent with it in some constitutions would be morbid in others. It is equally obvious that there is some latitude in its use, and that many changes may take place, without inducing a lesion of the functions, and, of course, a disease. Authors have, therefore, used the expression, "within the limits of health," to imply some deviation from the most perfect, but not sufficient to constitute a morbid, state.

Health depends on the management of what has been called the *non naturals*, a fanciful term, compre-

hending air, food, exercise, the passions, retenta and excreta, sleep and waking. Yet the regulation of these depends on the constitution, what has been styled temperament or idiosyncrasy: the former a generic term, comprising peculiarities of constitution, common to many persons; the other the peculiarity of each individual's structure. We must not now anticipate the subject of temperaments, but may remark that the ancients, in subservience to their doctrine of humours, distinguished four; the sanguine, the bilious, the phlegmatic, and the melancholic. The distinction is not wholly theoretical. The supposed sanguine temperament is that of youth, where the vessels are full, the fibres firm and active, quickly excited to motion, and often to excessive or irregular action. The bilious is distinguished by equal strength and activity; but by a yellow hue on the skin, red hair, with a constitution often more acutely sensible, always more irritable. The phlegmatic temperament is pale in complexion; languid in its exertions; the vessels, if full, torpid; the constitution inactive; the mind not easily excited to exertion. The melancholic has a greater degree of torpor, with a dark yellow hue; the mind dull, abstracted, but persevering. In such constitutions the plethora is chiefly venous.

The *sanguine* temperament bears evacuations with great ease; but they soon constitute a habit which is seldom broken with impunity. Health, with such persons, is best preserved by low living, avoiding excess of every kind, particularly cold after active bodily exertions. The *bilious* requires the same precautions; but the evacuations best adapted, which are indeed almost indispensable to this kind of constitution, are the free and frequent use of the milder laxatives. The warm cordial diet, and the stimuli, which suit the *phlegmatic temperament*, would induce fever in the sanguine or bilious. Free air, regular and constant exercise, with every means of strengthening, without constriction, are adapted for persons of this class. They will not bear evacuations, particularly loss of blood; and, at the same time, must not indulge too freely in high living or inactivity. In the *melancholic*, every thing which accumulates the blood in the internal organs must be avoided. Exercise, which determines to the skin; purgatives, which can rouse the torpid fibres into active exertions; amusements, which can interest the mind; are peculiarly necessary in such habits. A sameness of exercise and of objects, mental or corporeal, must be avoided; for the bent which the body or mind takes, is with difficulty counteracted.

Health is also a relative to different ages, to different sexes, and different occupations. Infancy is the period of peculiar irritability, and of peculiar sensibility. It is the sanguine temperament of manhood, with the mobility of the female constitution. As the body increases in size and in bulk, the mobility lessens, the strength and the activity of the sanguiferous and nervous systems augment. The power is at its height from about twenty-eight to thirty-five, and then gradually declines, assuming, by slow degrees, some of the more distinguishing appearances of the melancholic temperament, but not so acutely marked. In the early and later periods, the limits of health are more narrow; in the middle period, extensive; and the means of preserving it in both will

be sufficiently obvious from what has been already remarked.

Different sexes differ also in the means of preserving health. The constitution of women is that of youth: in advanced age the sexes approach very nearly in temperament. Women are generally distinguished by a plethora, and this is often a cause of apparent debility. The circulation is also balanced with peculiar nicety, so that the equilibrium is soon destroyed. The two distinguishing eras in a woman's life are, when the catamenia first appear, and when they cease. In each, before the equilibrium is established, either a morbid, irregular mobility, or a torpor, takes place. In the latter case the temperament approaches the phlegmatic. We have no appellation for the former; and another temperament should be added to express it, which may have the hackneyed appellation of the *nervous*.

The health as adapted to different occupations also differs. The sturdy strength of the husbandman would be torpor in the watchmaker; and the delicate feelings, the acute eye, and minute exactness of the latter, would be morbid sensibility in the sailor. Habit, in these instances, forms the constitution; but the limits of health are in each peculiarly his own. The diet of the one would be injurious to the other: the robust exercises of the sailor would bring on a morbid tremor in the artist. For active exertions and continued labour the diet should be chiefly animal, but not in excess: the vessels must be full, not distended. This is the training of the pugilist and the game cock, whose contests require the most vigorous exertions; and sometimes their continuance.

Health is also relative when there is any constitutional disease. In gouty habits it is necessary often to reduce the stronger state of the constitution; but it must be done with caution, lest the atonic form of the disease should follow. Scrofula, the disease of the phlegmatic constitution, will also not admit of stimulants; and, in each, we must keep to those extreme limits of health, which in many constitutions might be called debility. In nervous complaints we often find plethora at least a remote cause, and to lower the tone more may increase the irritability, and consequently the disease. We must here also keep to the extreme limits, and cautiously regulate our evacuations, lest the patient sink too low.

Idiosyncrasy is, in part, constitutional, but often induced by habit. It can be taught only by observation, and generally by the observation of the individual. No prudent physician will, therefore, employ an active medicine, until, from the patient or his friends, he has attempted to ascertain any peculiarity of constitution, which should render him cautious in this respect, or wholly forbid its being given.

The more general rules for the preservation of health we have already considered. See ALIMENT and DIÆTA; for the remainder of the subject, see ÆORA and CLIMATE.

HYGIE'NE, (from *υγιανω*, to be in health). The doctrines of health. See HYGIEIA and MEDICINA.

HYGIENI'STES, (from the same). *Hygienists*; physicians who only attend people in health, to prevent diseases. The temperaments, the constitution, the air, the food, the habitations, the changes in the functions of the body, and those from different ages,

seasons, and climates, were the objects of their attention.

HY'GRA (from *υγρος*, humid). LIQUID PLASTERS. See also COLOPHONIA.

HYGROBLEPHA'RICUS, (from *υγρος*, humid, and *βλεφαρον*, an eyelid). *Hygrophthalmicus*. An epithet of some ducts discovered in the extreme edge or inner part of the eyelids, leading probably from glands.

HYGROCIRSOCE'LE, (from *υγρος*, humid, *κισσος*, a varix, and *κηλη*, a tumour). A species of hernia, from a varicous spermatic vein, while the scrotum is at the same time filled with water.

HYGROCOLLY'RIMUM, (from *υγρος*, humid, and *κολλυριον*, a collyrium). A liquid collyrium, or consisting chiefly of liquids.

HYGROLO'GIA, (from *υγρος*, liquid, and *λογος*, a discourse). HYGROLOGY, which treats of the various humours of the body. The best works are Plenck's *Hydrologia*, and Johnson's *Animal Chemistry*.

HYGRO'METRUM. The HYGROMETER, (from *υγρος*, humid, and *μετρον*, a measure,) an instrument which shows the different degrees of moisture in the atmosphere. Wedelius gives this name to those diseased parts whose susceptibility of impressions shows different states of the air, with respect to its moisture, more exactly than any instrument. As, the cicatrices of old wounds are painful when the weight of the atmosphere is less, or rheumatic pains exasperated by a change of weather. The hygrometer has never been applied to medical purposes.

HYGROMY'RON, (from *υγρος* liquid, and *μυρον*, ointment), a liquid ointment described by Ætius.

HYGROPHO'BIA, (from *υγρος*, liquid, and *φοβησθαι*, to be afraid). Synonymous with HYDROPHOBIA, q. v.

HYGROPTHA'LMICUS. See HYGROBLEPHA'RICUS.

HYME'NEA, corrupted from *anime*, or *animæa*, COURBARIL. (See ANIME.) The seeds are covered with a saccharine substance, which the Indians eat greedily; and at the roots is found a yellowish resin, which, dissolved in alcohol, makes an excellent varnish. It is the gum anime of the materia medica.

HY'MEN, *υμην*, a MEMBRANE; from *Hymen*, the god of marriage, as by it is usually understood the membrane which appears in the form of a crescent, situated at the entrance of the vagina, called also *claustrum virginitalis*, *eugeos*, and *bucton*; supposed to be torn in the first intercourse with man. When this membrane is ruptured, it is shrivelled up, and forms the *caruncula myrtiformes*. (See CARUNCULA.) It naturally shrinks with years, or is torn by straining, and sometimes disappears before the age of twenty: it can, therefore, be no proof of virginity.

In infants this membrane is shrivelled, and appears a mere rugosity, so that De Graaf thought it wanting: in others it closes up the urethra, that the urine cannot be voided; or the vagina, that the menses cannot flow and an operation is necessary.

When the mark of perforation cannot be seen, the cure was thought impracticable; but a trochar and canula have been found to succeed, though a passage of four inches was perforated before the end was obtained. See Heister's Surgery; Edinburgh Medical Commem-

taries; Dr. Sherwin's Account of an Imperforated Hymen Successfully Treated; Medical Records and Researches, 1798.

HYOGLOSSUS, (from *υοειδης*, the hyoid bone, and *γλωσσα*, the tongue). The name of the muscle of the tongue. It rises from the basis, but chiefly from each cornu of the os hyoides, running laterally and forwards, to shorten the tongue. This muscle is sometimes divided into three: *basio glossus*; *hypsilo* or *ypsiloglossus*, or *hypsiloides*; the *chondro glossus*; and the *ceratoglossus*. Douglas observes, that it rises fleshy from three different places; its first origin is broad and carnosus from the cornua of the hyois; this is properly the *ceratoglossus*: its second head comes from part of the basis of this bone, and its name is *hasioglossus*: the third beginning is derived from the cartilaginous appendage of the hyoides, sometimes called *chondroglossus*: these three unite, and, their fibres running in the same direction, they are inserted broad and thin near the root of the tongue laterally. The use of each is to draw the tongue obliquely to one side; but if both act at once, the tongue is pulled directly backwards into the mouth. Douglas adds, that in some subjects he hath observed a great part of the muscles to arise from the basis of the bone, and in some others few or none of their fibres originated from that part.

HYOIDES OS, (from *υ*, and *ειδος*, because formed like the Greek letter *upsilon*,) *yoides*, *hypsiloides*, and *upsiloides*; *bicorne*, and *lambdoides*. It is situated in an horizontal position between the root of the tongue and the larynx; convex on its anterior part, and hollow on the posterior: the cornua become smaller as they run back, and diverge a little; at the end of each cornu is a graniform appendicle, from whence a ligament runs to the styloid process of the os temporis, and another ligament connects the bone to the larynx. These ligaments are sometimes in part or wholly osseous, and the os hyoides is joined to the temporal bone by ankylosis. In the fœtus it is almost wholly cartilaginous, only a small osseous point appearing in the middle of its body and in each of its cornua. The appendicles are not observable at birth, and remain cartilaginous for many years, it is the basis and support of the tongue, and the muscles of the larynx and fauces.

HYOPHARYNGÆUS, (from *υοειδης*, the hyoid bone, and *φάρυγξ*, the pharynx). The hyopharyngæi muscles, in general are those which on each side are inserted into the os hyoides; and they may be reckoned three pair, viz. the *basio pharygæi*, *cerato pharyngæus major et minor*; coming from the basis and the horns of the os hyoides. Innis calls it *constrictor pharyngis medius*. It arises from the appendix of the os hyoides, from the cornu of that bone, and from the ligament which connects it to the thyroid cartilage; the fibres of the superior part, running obliquely upwards, and covering a considerable part of the superior constrictor (i. e. *cephalo pharyngæus*;) terminate in a point. It is inserted in the middle of the cuneiform process of the os occipitis, before the foramen magnum, and jointed to its fellow at a white line, in the middle back part of the pharynx. The fibres at the middle part run more transversely than those above or below. Its use is to compress that part of the pharynx which it covers, and to draw it with the os hyoides upwards. See PHARYNX.

HYOPHTHALMOS, (from *υς*, a swine, and *οφθαλμος*, an eye). HOG'S EYE; so named from its resemblance. See ERYNGIUM.

HYOSCIAMUS, (from *υς*, a swine, and *κυμας*, a bean; from hogs eating it as a medicine; or from the hairy and bristly appearance of the plant). HENBANES; HOG'S BEANS, and *dens caballinus*. The plants have hairy, oblong, deep indented leaves, and bell shaped flowers, followed by irregular cup like capsules, which contain the seeds. It is also a name for tobacco. See NICOTIANA.

HYOSCIAMUS ALBUS, Lin. Sp. Pl. 257. WHITE HENBANE. Its leaves are smaller and more woody than those of the black henbanes; the plant is a native of the southern parts of Europe; is similar, but not equally powerful, with the common sort. Sauvages observes, that the daily use of the hyosciamus albus, beginning with the third part of a grain, and gradually increasing it while the œsophagus and fauces are moist, is the most efficacious remedy for a cataract. A priest, affected with this complaint in his right eye, after the use of this medicine for eight days, in which time the dose was increased to three grains, could read small print, who before could only perceive large letters. The crystalline lens was at first white, afterward became bluish and nearly pellucid; the myodal suffusion, under which he laboured, vanished, but the appetite and sleep, at first languid, were perfectly restored. From the use of this medicine he saw another cured by *D. Coulas*, whose crystalline lens became perfectly diaphanous. Sauvagesii Nosologia Methodica, vol. i. p. 724.

HYOSCIAMUS LUTÆUS. See NICOTIANA MINOR.

HYOSCIAMUS NIGER, *aphollinaris altercum*, *fabasvilla*, *agone*, *altercangenon*, COMMON OR BLACK HENBANE; *hyosciamus niger* Lin. Sp. Pl. 257; is one of the poisonous vegetables of Great Britain. The root is long, tough, white, and, when recently cut through, smells like liquorice: the stalks thick, round, woody, irregularly branched, and covered with a hairy down. The leaves surrounding the stalk at their base stand irregularly; are large, soft, and downy, pointed at the ends, and very deeply indented at the edges; of a greyish green colour, with a virose disagreeable smell. The flowers are monopetalous, divided into five obtuse segments; large, of a dirty yellowish colour, reticulated with violet coloured veins. The seed vessels follow, one after every flower: they are large, and contain a great quantity of seeds of a brown, rough, and irregular figure.

This is the only species a native of Great Britain; and the seeds, leaves, or roots, if received into the stomach, are poisonous. The root produces various disorders, and particularly madness. If the stomach does not reject what it has received, a stupor and apoplectic symptoms, terminating in death, are the usual consequences.

Henbane, in its external appearances, much resembles parsnep, the use of which is said to be dangerous; the latter has probably been mistaken for parsnips.

The symptoms in consequence of swallowing this species of henbane, besides madness, are apoplexy, or an appearance of intoxication. Swallowing the seeds has been sometimes followed by thirst, giddiness, dimness

of sight, with a dilated pupil, raving, and profound sleep. The effects of henbane are similar to those of opium, when taken in large quantities; and, like opium, if administered with skill, it is a valuable sedative, moderating excess of irritability. With the advantages of opium, it is said to keep the bowels lax, especially if exhibited in large doses. It has been given in the form of extract as far as twenty-four grains; but the dose has been gradually increased from one or two grains: it seldom produces any anodyne effect till it has amounted to eight or ten grains. Dr. Cullen has extended it to thirty grains a day.

Its ill effects are relieved as directed in the article AMANITA, q. v.

Dr. Stork is said to have relieved by this remedy palpitations of the heart, a tendency to melancholy, coughs, with other spasmodic disorders and convulsions after other means had failed. But Greeding tried it in forty cases of melancholia, mania, and epilepsy, without advantage. In cancers and scrofula it has been tried with various degrees of success. In chordees, which have resisted the use of opium, Bell used it with advantage, giving the extract from one to three grains, sometimes a larger dose, three times a day. See Stoerck de Hyosciamo, and Lewis's *Materia Medica*.

The author of this article, led many years since by circumstances unnecessary to mention, tried the seeds of the hyoscyamus in different cases of hysteria, and other convulsive diseases of the stomach. Either alone or mixed with aromatics he found it a valuable sedative, without the deleterious or the constipating effects of opium, and only neglected it from omitting to procure the seeds in proper time. He began with a grain, and seldom found it necessary to proceed beyond three or four.

Lewis's *Materia Medica*, p. 315; Wilmer's *Observations on the Poisonous Vegetables in Great Britain*; Withering's *Botanical Arrangements*; *Memoirs of the Medical Society of London*, vol. i. p. 310; Cullen's *Materia Medica*.

HYOTHYROIDES, (from *vos*, the hyoid bone, and *θυροειδες*, the thyroid cartilage). *Thyro hyoides*. These muscles run from the thyroid cartilage to the os hyoides: they are attached to the knobs of that cartilage, and the line between them, for the purpose of bringing them nearer to each other.

HYPALÉIPTRON, (from *υπαλειφα*, to spread). A spatula for spreading ointments.

HYPALÉIPTON, (from the same). See LINIMENTUM.

HYPERÆSTHESES, (from *υπεραισθη*, to feel in excess). See DYSÓREXIA.

HYPERARTETISCOS, (from *υπερ*, above, and *αριζω*, to compose). Supernumerary parts or members.

HYPERCATHARSIS, (from *υπερ*, a preposition signifying excess, and *καθαρσις*, purgation,) *hyperinesis*, and *hyperinos*; excessive purging from medicine; a variety of the *diarrhœa mucosa* of Dr. Cullen. It is not only produced by the irritability occasioned by the too violent action of purging medicines, but from any other cause of irritation in the bowels. The cure is similar to that of violent diarrhœas. Gentle anodynes, frictions, and diaphoretics, were much depended on by the ancients. See Oribasii *Medic. Collect. lib. xiv. cap. 42*.

P. *Ægineta*, lib. vii. cap. 7. *Ætius Tetrabiblicon serm. 3. cap. 118*.

HYPERICOIDES, (from *hypericum*, *St. John's wort*, and *ειδος*, likeness). See HYPERICUM SAXATILE.

HYPERCORYPHOSIS, (from *υπερ*, above, and *κορυφη*, the vertex). A PROMINENCE, OR PROTUBERANCE. See JECUR and PALMO.

HYPERCRISIS, (from *υπερ*, above, and *κρισις*, a crisis). AN HYPERCRISIS, OR SUPER-EXCRETION; such excessive critical evacuations as endanger the patient.

HYPEREPHROSIS, (from *υπερ*, excess, and *ιδρως*, sweat). IMMODERATE SWEATING.

HYPERICUM, (from *υπερ*, above, and *εικων*, image, or spectre; because it is supposed to drive away evil spirits). ST. JOHN'S WORT, *perforata*, *fuga dæmonum*, *androsæmum*, *hypericum vulgare*; *hypericum perforatum* Lin. Sp. Pl. 1105. PERFORATED OR COMMON ST. JOHN'S WORT.

This plant has slender, round, reddish, woody stalks; small, obtuse, oblong leaves, set in pairs, which, when held to the light, seem to be perforated; numerous gold coloured pentapetalous flowers on the tops of the branches, followed by blackish husks, full of small seeds. It is perennial, grows wild in the hedges and uncultivated places, and flowers in June and July.

The flowers abound with resin, but with the aid of its abundant mucilage, water dissolves all its active parts. The leaves also contain much resin. Distilled with water, an essential oil is obtained, resembling that of turpentine. To the taste the leaves and flowers are bitterish and subastringent; but though not much used at present, it was in great repute with the ancients; internally in hysteria, hypochondriasis, mania, ulcers hæmoptysis, bloody urine, gravel, dysentery, agues, worms, wounds, and bruises; and, outwardly, as an anodyne and a discutient. In the London Pharmacopœia the flowers are preferred, as containing the greatest proportion of the resinous matter, in which the medical efficacy of the plant is supposed to reside. The dark puncta of the petals, which are vesicles or glands, afford the essential oil of this plant, and give a red colour to rectified spirit and to expressed oils; the latter of which has been long known by the name of *oleum hyperici*. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

It is the name also for the spiræa and coris.

HYPERICUM SAXATILE. &c. BASTARD ST. JOHN'S WORT; *hypericoides*; *coris lutea*, and *coris legitima Cretica*. The seeds are said to be diuretic, emmanagogic, and powerfully antispasmodic.

HYPERINE/SIS, and HYPERINOS (from *υπερ*, in excess, and *ινω*, to purge). Synonymous with HYPERCATHARSIS, q. v. and the person who suffers from it.

HYPERO'A, (from *υπερ*, above, and *οσ*, os). See PALATUM.

HYPERO-PHARYNGÆI, (from *υπερ*, above, and *φαρυγξ*, the pharynx). See PERISTAPHYLOPHARYNGÆI.

HYPEROSTOSIS, (from *υπερ*, upon, and *οστεον*, the bone). A swelling of the whole bone. In Cullen's *Nosology* it is synonymous with *exostosis*.

HYPERSARCOMA. A fleshy excrescence. See also POLYPUS NARIUM.

HYPERSARCO'SIS, (from *υπερ*, *excess of*, and *σαρξ*, *flesh*), a fleshy excrescence, or proud flesh.

HYPE'XODOS, (from *υπερ*, *under*, and *εξοδος*, *a passing out*). See **DIARRHŒA**.

HYPE'ZOCOS; membranes spread under other parts, as the pleura.

HYPNO'BATES, and **HYPNOBA'TASIS**, (from *υπνος*, *sleep*, and *βαινω*, *to go*). See **SOMNAMBULO**.

HYPNOLO'GIA, (from *υπνος*, *sleep*, and *λογος*, *a discourse*), instructions relative to the due regulation of sleep and waking.

HYPNOPE'OS, and **HYPNO'TICUS**, (from *υπνος*, *sleep*, and *ποιω*, *to cause*). **HYPNOTICS**, medicines which procure sleep. See **ANODYNA**.

HY'PO, *υπο*. A preposition signifying *under*; but, in composition it imports not only inferiority with respect to situation, but a remission or diminution.

HYPOCAPNI'SMA, (from *υπο*, *under*, and *καπνιζω*, *to smoke*). See **SUFFUMENTUM**.

HYPOCAROD'ES, and **HYPERCARO'THIS**, (from *υπο*, *sub*, and *καρος*, *carus*). One who labours under a low degree of a carus.

HYPOCATHA'RSIS, (from *υπο*, *sub*, and *καθαριω*, *purgo*). A SLIGHT-PURGING.

HYPOCAU'STUM, (from *υπο*, *under*, and *καιω*, *to burn*). See **CALADARIUM**.

HYPOCERCHNA'LEON, (from *υπο*, and *κερχειος*, *an asperity of the fauces*), an asperity of the fauces and aspera arteria, occasioning a stridulous breathing.

HYPOCHEO'MENOS, (from *υποχωω*, *to suffuse*). One who labours under a cataract.

HYPOCHO'NDRIA, (from *υπο*, *under*, and *χονδρος*, *a cartilage*). The hypochondria are those viscera on each side, which lie under the spurious ribs; extending to the ilia, and comprehending not only the muscles, but the internal parts; because they are subjacent to cartilages. Celsus, from several places in Hippocrates, renders the word *præcordia*. Cælius Aurelianus does the same. The state of tension in the hypochondria should be examined in every fever.

Affections of the hypochondria, according to Hippocrates, are, *hypochondrion anesphasmenon*, a retraction of the hypochondrium inwards, without any proper disorder of the part; *hypochondria diaborhorizonta*, a rumbling of the hypochondria; *hypochondrii entasis*, a softish tension of the hypochondria; *hypochondria catexerasmena*, the hypochondria dried up and contracted inwardly; *hypochondria meteora*, raised by flatulencies; *hypochondria xyntasis*, a distention of the hypochondria from inflammation; *hypochondria scolitoes*, an inequality of the hypochondria; *hypochondrium chronium*, an hypochondrium affected with an obstinate disorder: and

HYPOCHONDRI'ACUS MO'RBUS, (from *υποχονδριος*, *the hypochondrium*). The **HYPOCHONDRIAC DISEASE**; *affectio hypochondriæ*, *passio hypochondriaca*, **HYPOCHONDRIASIS**, **VAPOURS**, **SPLEEN**, &c.

Hoffman, with great propriety, contends, that *hypochondriasis* is not the same disease as *hysteria*. He observes, that a strangulation of the fauces, a quick and difficult respiration, endangering suffocation, loss of speech and motion, are the proper and essential symptoms of the hysteria: that the hypochondriasis is inveterate, and rarely so effectually relieved as not to be again easily excited; that though many of their symptoms are

the same, yet they each have such as is essential to it. Many others comprehend these two disorders under the general title nervous; and think that they only differ as affecting different sexes, or by the flatulence of the stomach, which distinguishes hysteria. Dr. Cullen places hypochondriasis in the class *neuroses*, and order *adynamia*; and defines it indigestion, with languor, sadness, and fear, from uncertain causes, in a melancholic temperament. One idiopathic species is only known. The state of mind peculiar to hypochondriacs is thus described by Dr. Cullen. "A languor, listlessness, or want of resolution and activity, with respect to all undertakings; a disposition to seriousness, sadness, and timidity; as to all future events, an apprehension of the worst or most unhappy state of them; and, therefore, often upon slight grounds an apprehension of great evil. Such persons are particularly attentive to the state of their own health, to every the smallest change of feeling in their bodies; and from any unusual sensation, perhaps of the slightest kind, they apprehend great danger, and even death itself. In respect to these feelings and fears, there is commonly the most obstinate belief and persuasion." He adds, that it is only when the state of mind just described is joined with indigestion, in either sex, somewhat advanced in years, of a melancholic temperament, and a firm and rigid habit, that the disease takes the name of *hypochondriac*. The seat of the hypochondriac passion is in the stomach and bowels; for, first, these parts are disordered, then the others suffer from the connection. In this Hoffman agrees, by saying the peristaltic motion in the bowels is retarded by spasms.

The causes are, sorrow, fear, or excess of any of the passions; too long continued watching; irregular diet. Those habitually disposed to it—and these causes have little effect in other constitutions—have generally a sallow or brown complexion, and a downcast look, a rigidity of the solids, and torpor of the nervous system. Whatever may occasion nervous disorders, in general, may be the cause of this in particular.

The signs of this complaint are so various, that to describe them is to describe almost every other disease; but in general there is an insurmountable indolence, dejected spirits, dread of death, costiveness, a slow and somewhat difficult inspiration, flatulencies in the primæ viæ, and various spasmodic affection. It is seldom fatal; but if neglected, or improperly treated, may bring on melancholy, jaundice, madness, or vertigo, palsy, and apoplexy.

The hypochondriac disease is very difficult to cure: it rarely occurs early in life, generally in more advanced years only; and when once it has taken place, it increases as life advances. Indigestion, accompanied with vapours, distinguishes the disease when the temperament is of this peculiar kind.

If the disease admits of a cure, it is by means slow and steady in their operation; for the whole constitution must be corrected before any expectation of relief can be obtained. In these cases the mind must be cheered by every pleasing prospect; by assurances of a cure; by change of place and objects; by engaging it in any employment which will interest without fatiguing. For these purposes the fashionable mineral waters may be drunk on the spot, and they should be of the

mildly cathartic kind, as those of Cheltenham, Seltzer, or Tunbridge; but the cathartic waters are, on the whole, preferable to those which contain steel among their impregnations, though this medicine is not particularly injurious.

If these plants cannot be admitted, an active emetic should be given, and repeated every three or four days; a small blister applied to the neck; and the bowels kept freely loose by the pillulæ ex aloe cum myrrhâ, or the tinctura aloes. Dr. Cullen observes, that in the hypochondriasis there is a want of activity, not a loss of tone, in the fibres, but, on the contrary, a rigidity in them; and he recommends warm bathing; drinking tea and coffee; exercise, not merely to excite the activity of the stomach, but to divert the mind from its dependancy.

Astringents are generally improper. As there is usually an acid in the stomach, bitters may be given with the alkaline salts and rhubarb: but chalybeates are of more uncertain efficacy; and bark, in general, is injurious; though, when attended with flatulence, aromatics may be sometimes allowed.

In managing the minds of hypochondriacs, any intimation that their complaints are imaginary, must be avoided, and neither raillery nor reasoning in addressing them employed. Their attention should be engaged with any object but their own feelings; diverted with any employment not attended with emotion, anxiety, or fatigue. Diversion, in which some skill is required; exercise in the air, which requires some dexterity, are both to be admitted: riding is better than either walking, sailing, or travelling in a carriage; and a distant journey is the best. The study of botany, which combines exercise with employment, has been highly salutary.

If pain and flatulence, accompanied with an headache, attend, a slight anodyne may be admitted; and if spasmodic symptoms are considerable, tending to convulsions, relief may be obtained by means of opiates, joined with fetid gums, or with musk.

Warm bathing in pure water, heated sufficiently to raise Fahrenheit's thermometer to ninety or ninety-two, should be continued until some relief is obtained, and then gradually the cold bath may be substituted. Cheerful company conduces much to relief; but boisterous mirth, or any exercise carried so far as to fatigue, are injurious. A dry warm air is almost universally proper. See NERVOUS DISEASES; Hoffman on the Morbus Hypochondriacus; Cullen's First Lines, vol. iii. edit. 4.

HYPOCHONDRI'ASIS. See HYPOCHONDRIACUS MORBUS.

HYPOCHY'MA, and HYPOCHY'SIS, (from *υπο*, and *χυω*, to pour; because the ancients thought that the opacity proceeded from something running under the crystalline humour). See CATARACTA.

HYPOCI'STIS, (from *υπο*, under, and *κιστις*, the cistus). The RAPE OF CISTUS; *orobanche*; *cytinus hypocistis* Lin.; not inserted in the last edition of his species, but formerly referred to the genus *asarum*; *asarum hypocystis* Lin. Sp. Pl. 633. The inspissated juice of this plant is of a firm consistence, and a bright black colour; of a mild astringent taste; and of similar medical virtues with the Egyptian acacia, though

differing from it by almost totally dissolving in rectified spirits of wine. See Raii Historia Plantarum; Lewis's Materia Medica. Both this and the acacia are equally disused; and both were employed in checking profluvia.

HYPOCLE'PTICUM VITRUM, from *υπο*, under, and *κλεπτω*, to steal; because it seems to steal away the water from the oil. See SEPARATORIUM.

HYPOCCE'LON, (from *υπο*, under, and *κοιλον*, a cavity,) a cavity under the lower eye lid. See Rufus Ephesius, lib. i. cap. 4.

HYPOCOPHO'SIS, from *υπο*, under, and *κοφωσις*, deafness). A less degree of cophosis.

HYPOCRA'NIUM, (from *υπο*, under, and *κρανιον*, the skull). An abscess seated under the cranium, between it and the dura mater.

HYPOCRATERIFO'RMIS, (from *υπο*, *κρατηρ*, a cup, and *forma*, likeness). Botanically it is applied to a corolla, when it extends horizontally, like a salver, or, in a small degree, like a cup.

HYPO'DERIS, (from *υπο*, sub, and *δερσις*, the skin). In Rufus Ephesius, it is the extremity of the fore part of the neck.

HYPODE'RMIS, (from *υπο*, and *δερμα*, the skin). See CLITORIS.

HYPOGALA, (from *υπο*, under, and *γαλα*, milk). A collection of white fluid in the eye, supposed to be sometimes a lacteal deposition in women who give suck; sometimes owing to the wounding a milky cataract in the operation of couching.

HYPOGA'STRICA SE'CTIO, (from *hypogastrium*). See LITHOTOMIA.

HYPOGA'STRICÆ ARTE'RIÆ. See ILIACÆ ARTERIÆ for the external hypogastric arteries. The hypogastric or internal iliac artery sinks into the inside of the pelvis, just over the edge of the sacrum: when it arrives there its branches extend to the contents of the pelvis, and then go through the sciatic notch. In the fœtus the internal iliac is larger than the external, because it supplies the placenta. After birth it consequently shrinks, and makes the chord, which was before the umbilical vessels.

HYPOGA'STRICÆ VE'NÆ. These veins run the same course with their corresponding arteries, except that they do not send off the vena umbilicalis. The hypogastric veins are the internal iliac branches.

HYPOGA'STRIUM, (from *υπο*, under, and *γαστηρ*, the stomach). *Aqualiculus*; *etron*; sometimes *imus venter*; is the lower external region of the fore part of the belly, extending from the lower extremity of the regio umbilicalis, to the bottom of the ossa innominata. It is divided into the pubes before, and the groins on each side. When the integuments are removed from this region you discover the linea alba, the lineæ scmilunares, and the lineæ transversæ.

HYPOGASTROCE'LE, (from *υπογαστριον*, *hypogastrium*, and *κελη*, tumour). See HERNIA VENTRALIS.

HYPOGLO'SSI EXTE'RNI vel MAJO'RES, NE'RVI, (from *υπο*, under, and *γλωσσα*, a tongue,) *linguales* and *gustatorii*; the ninth pair of nerves, which arise just above the foramen magnum, and pass out at the holes on its sides above the condyles of the os occipitis. As soon as they have passed out of the cranium, they run betwixt the carotid artery, and the internal

jugular vein, to the tongue, on the side of the digastric muscle.

HYPOGLO'SSIS, and **HYPOGLO'SSUM**, (from *υπο*, *under*, and *γλωσσα*, *the tongue*.) is that part of the tongue which adheres to the lower jaw, and the seat of the disease called *rana*, whence *Ætius* names it *υπογλωσσιος βαλεραχιος*, *the frog under the tongue*. See **RANULA**.

HYPOGLO'TTIDES, (from *υπο*, *sub*, and *γλωττα*, *the tongue*.) a lozenge to be held under the tongue until dissolved. It sometimes is the appellation of the glands under the tongue.

HYPOGLU'TIS, (from *υπο*, *under*, and *γλουτος*, *the breech*.) the fleshy part under the nates towards the thigh. The flexure of the coxa, under the nates, has sometimes this appellation.

HYPO'MIA, (from *υπο*, *under*, and *ωμος*, *the shoulder*.) the part subjacent to the shoulder. Galen.

HYPO'NOMOS, (from *υπο*, *under*, and *νομη*, *a phagedenic ulcer*.) a deep sinuous phagedenic ulcer.

HYPOPE'DIUM, (from *υπο*, *sub*, and *πους*, *feet*, *the foot*.) A cataplasm for the sole of the foot.

HYPOPHA'SIA, (from *υποφαινομαι*, *to appear a little*.) winking when the eye lids are nearly closed.

HYPO'PHASIS, (from the same.) A symptom which consists of closing the eyes during sleep, but partially, so that a slight motion of the eye and a portion of the organ are perceived.

HYPO'PHORA, (from *υποφερομαι*, *to be carried or conveyed underneath*.) A deep fistulous ulcer.

HYPOPHTHA'LMION, (from *υπο*, *sub*, and *οφθαλμος*, *the eye*.) The part under the eye subject to swell in a cachexy or dropsy.

HYPOPHYLOSPE'RMI, (from *υπο*, *under*, *φυλλον*, *a leaf*, and *σπερμα*, *seed*.) Such plants as bear their seed on the back part of their leaves.

HYPO'PHYSIS, (from *υπο*, *under*, and *φω*, *to produce*.) - See **TRICHIA**.

HYPO'PIA, (from *υπο*, and *ωψ*, *oculus*.) Sugillations in the part under the eye.

HYPOPLEU'ROSIS. See **PLEURA**.

- **HYPOPYON**, (from *υπο*, *under*, and *πυον*, *pus*.) *Pyosis*, and *abscessus oculi*. The disease has been considered to arise from a collection of pus under the cornea; but this idea is, at least, imperfect, if not erroneous. The matter is not confined to the anterior chamber of the eye, nor is it purulent. It sometimes collects in the posterior chamber, and is never truly pus, but that kind of sebaceous mucus which is found between the eye lids of diseased eyes, or of a consistence between this and what is found effused on inflamed membranes after death. The hypopyon is, at least, never the consequence of the real ulceration which takes place between the laminæ of the cornea.

It is the exudation of the gluten, in consequence of inflammation, which first falls to the bottom of the aqueous humour, appearing there in the form of a crescent, from the capillary attraction of the sides of the coats. It gradually fills both chambers, passing through the pupil, and conceals the iris; but, after the active period of inflammation ends, seems to increase no further. After this period, also, it gives little pain; and common people, as well as children, bear it as an unavoidable effect of ophthalmia, with little uneasiness, and as little complaint.

As the hypopyon is with difficulty removed, it should be with the utmost care prevented. When therefore it is threatened, the remedies of ophthalmia should be employed with augmented rigour and activity, to prevent its occurrence or increase. When it has taken place, friction has been employed to promote its absorption, or we have been directed to puncture the cornea to discharge it. It is easy to direct both; and the surgeon, after he has given these directions, seems to rest in security. Nothing is more fallacious than such indiscriminate advice.

Friction, in a supine posture, as recommended, is often injurious by increasing the inflammation, and consequently the exudation. It is at the same time highly painful, and cannot be continued.

The division of the cornea to discharge the matter is a more obvious measure. Many inconveniences, however, attend this operation; and not the least is the inflammation which the operation excites, by which the disease is exasperated. If, according to Richter's advice, the aperture is small, the time required for the discharge of the viscid fluid is so long, that the edges of the wound suppurate, the iris is prolapsed, and the crystalline often discharged. At best, we substitute an ulceration of the cornea to the hypopyon. There is, indeed, one case in which the operation may be risked, with all its inconveniences, where the distention is so great as to bring on inflammation, and destroy the organ. In general, it is better to trust to absorption, which Janin supposed to be accelerated by decoction of mallows, and others by an infusion of sage; but these act as emollients only.

Other practitioners have employed, to promote absorption, bags of tepid mallows, with some camphor, or the vitriolic collyrium, with mucilage of quince seeds, varying the proportions according to the degree of sensibility; for, though it should be always felt to irritate, the irritation should not be so considerable as to produce inflammation.

When the distention is so great as to destroy the organ, and to be near bursting, it may be opened, the crystalline suffered to escape, and the ball of the eye to sink, so as to admit of an artificial one. In this case the sight cannot be recovered: the pain may be relieved, and deformity prevented. When a natural opening occurs at an earlier period, so as to admit of a discharge, it may be allowed to proceed; for natural openings are not so injurious as artificial ones. In such cases, when the matter is evacuated the ulcer may be healed by touching its edges with the *argentum nitratum* in a diluted state.

See St. Yves on the Diseases of the Eye; Heister's Surgery; Bell's Surgery, vol. iii. p. 313, &c.; White's Surgery, p. 232; Scarpa on Diseases of the Eye; Richter Observationum Chirurgicarum, fasciculus i. cap. 12; Janin Memoirs, &c. sur l'Œil 99, p. 405.

HYPORI'NION, (from *υπο*, *sub*, and *ριν*, *the nose*.) the parts of the upper lip, below the nostrils.

HYPOSA'RCA, and **HYPOSARCI'DIOS**, (from *υπο*, *under*, and *σαρξ*, *flesh*.) See **ANASARCA**, and **PHYSICONIA**.

HYPOSPADIE'OS, (from *υπο*, *sub*, and *σπαιω*, *to draw*.) The urethra terminating under the glans.

HYPOSPATHI'SMUS, (from *υπο*, *sub*, and *σπαθη*, *a spatula*.) An operation formerly used in surgery for

removing defluxions in the eyes; named from the instrument with which it was performed. See P. Ægineta, lib. vi. cap. 6.

HYPOSPHIA'GMA, (from *υπο*, and *σφαζω*, vcl *σπατω*, *jugulo*). A suffusion of blood, and sugillation in the tunica adnata of the eye. This disease differs from an ophthalmia, though it proceeds from a blow, as it is not inflammatory. It sometimes arises from internal causes, as scurvy, and then antiscorbutics alone are necessary for the cure: if from a blow or contusion, bleeding must be employed, and repeated, in proportion to the pain, inflammation, and violence of the blow; leeches may also be applied to the eye lid, with the other remedies of ophthalmia.

HYPOSTAPHYLE, (from *υπο*, *sub*, and *σφαρην*, *the uvula*,) *procidencia uvulae; columella; craspedon*; is an elongation of the uvula, from relaxation, inflammation, or ulceration, attended with uneasiness and difficulty in swallowing, cough, nausea, commonly a continual spitting, sometimes a difficulty of breathing, and a stammering or faulty articulation. There are two species; one arising from inflammation, the other from relaxation. In the first, the uvula is swelled, hot, acutely painful, of a red or livid colour, and falls down in an altered form. Sometimes suppuration comes on, and the difficulty both of swallowing and breathing is more considerable than in the subsequent species. When this complaint is very violent, there is apparent danger of strangulation. It is cured by bleeding and purging; gargling with emollient and subastringent liquids, and sometimes scarification. In the second species, the uvula, preserving its natural colour, is relaxed, elongated, pale, cold, or œdematous. The cure then depends upon the application of spirituous, stimulant, and astringent-stimulants, with the internal use of cathartics and tonics. The following gargle, called *gargarisma aluminis*, is an excellent restringent: R. aluminis ℥ ij. decocti hordei ꝑ ij. mellis rosæ ℥ iij. misce. It is not only useful in cases of relaxed uvula, but wherever the topical use of astringents is required; in ulcerations of the throat, fauces, or gums. If it yields not to proper stimulant applications exhibited internally, as well as externally, the part must be amputated, and the hæmorrhage, if necessary, stopped by styptics.

HYPO'STASIS, (from *υποσθηνμι*, *to subside*). The sediment in urine.

HYPOTHE'NAR, (from *υπο*, *under*, and *θεναρ*, *the palm of the head*). See ABDUCTOR MINIMI DIGITI MANUS. It is also that part of the hand which is opposite to the palm.

HYPOTHESIS, (from *υποτιθημι*, *to suppose*). As the derivation implies, it is a gratuitous supposition employed sometimes to connect, sometimes to examine, the nature of facts; as the mathematician occasionally supposes an unknown number to be a given one, in order to try whether, when substituted, it will be found to solve the problem. If an hypothesis connects the facts, it is useful whether it be true or false, for it gives a facility of explanation by supplying language; and if given only as such will not mislead. A theory, on the contrary, is a fair philosophical induction from facts, leading to a ready and probable explanation.

HYPO'THETON, (from *υπο*, *under*, and *τιθημι*, *to put*). See SUPPOSITORIUM.

HYPOZO'MA, (from *υπο*, and *ζωννυμι*, *to bind round*). See DIAPHRAGMA.

HYPSILOGLO'SSUS, i. e. **BASIOGLOSSUS**, (from *υ*, *the hyoid bone*, and *γλωσσα*, *lingua*, *the tongue*). See HYOGLOSSUS.

HYPSILOI'DES, (from *υ*, *upsilon*, and *ειδος*, *likeness*). The OS HYOIDES, and the BASIOGLOSSUS MUSCLE. See HYOGLOSSUS.

HYPTIA'SMOS, (from *υπτιαζω*, *to lie with the face upwards*). A supine posture, or a nausea, with inclination to vomit.

HYPPU'LUS, (from *υπο*, *under*, and *ουλη*, *a cicatrix*). An ulcer which lies under a cicatrix.

HYSSOPIFO'LIA, (from *hyssopus*, *hyssop*, and *folium*, *a leaf*). See ADHATODA.

HYSOPHY'LLUM, (from *υσωπος*, *hyssop*, and *φλλον*, *folium*, *a leaf*). See BUPLEURUM.

HYSOPI'TES, (from *υσωπος*, *hyssop*). Wine impregnated with hyssop.

HYSO'PUS, (from the Hebrew word *azab*, *a holy herb*, or *a herb appointed for cleansing holy places*). *Hyssop*. *Symphytium petraeum; hyssopus officinalis* Lin. Sp. Pl. 796, is a low shrubby plant, with brittle branched stalks, square when young, but round when old. The leaves are oblong, narrow, and of a dark green colour; the flowers in loose spikes, of a blood colour. It is perennial, cultivated in gardens, and flowers in July and August.

The leaves have an aromatic smell, and a bitterish, warm taste. Water extracts the greater part of their virtues, but spirit more perfectly; and the extract made by evaporating the spirituous tincture scarcely loses any degree of the virtues of the plant. From about six pounds of leaves an ounce of essential oil may be obtained by distilling in water.

This plant is esteemed as an attenuant, corroborant, and expectorant; useful in humoral asthmas, coughs, and other disorders of the breast and stomach, accompanied with inflammatory symptoms. These virtues are, however, much disputed by modern writers, particularly Cullen. In these cases an infusion of the leaves may be sweetened with honey, and drunk at pleasure by those who still entertain a favourable opinion of this medicine. In a fomentation and poultice, in contusions, and for removing the blackness occasioned by the ecchymosis, hyssop has been considered an efficacious remedy. See Lewis and Cullen's *Materia Medica*.

HYSSO'PUS CAPITA'TA. See SERPYLLUM VULGARE.

HY'STERA, (from *υστερος*, *behind*, because placed behind the other parts). See UTERUS and INVOLUCRA.

HYSTERA'LGIA FEBRICO'SA. A QUOTIDIAN FEVER, with pain in the womb.

HYSTERIA'LGIA, (from *hystera*, *the womb*, and *αλγος*, *dolor*, *pain*). Whatever excites pain in the uterus resembling labour pains, and called *false*. See ACETUM.

HYSTE'RIA FEBRICO'SA. A TERTIAN FEVER, with spasms and convulsions.

HYSTE'RIA, (from *υστερα*, *the womb*, from which the disease was supposed to arise). **HYSTERIC**; an appellation of the midwives of Greece and Italy who practised medicine among women. It is one of those

disorders that ranks among the nervous, and arises from a preternatural irritability, owing very frequently to some change in the uterine system. Dr. Cullen places it in the class *neuroses* and order *spasmi*; defining it a rumbling noise in the belly, with the sensation of a ball rolling in the abdomen, ascending to the stomach and fauces, and there producing a sense of strangulation, drowsiness, convulsions, profuse quantity of pale urine; the mind, though not spontaneously, fickle and mutable. The varieties arise from the remote causes; a retention, or too copious flow of the menses; leucorrhœa; obstruction of the viscera; a defect in the stomach; lasciviousness. The belly is often tumid, and the navel is drawn inward; a general shivering with coldness often attends; a frequent discharge of very pale or limpid urine; costiveness; anxiety; pain of the head, as if a nail was fixed in it; palpitation of the heart; a general tremor; an unequal and languid, or a quick fluttering pulse; coldness of the extremities; a pale countenance; convulsive twitchings, increasing to the most violent spasms; alternate laughing and crying, are the most common symptoms. When the fit goes off, though the patient seems ready to expire, and lies for many hours apparently dead, the whole of the disorder disappears, and, in some instances, a perfect health is apparently restored. Hoffman observes, that hysteric patients rarely die without the attack of an epilepsy or apoplexy; from both which, and from syncope, it should be distinguished. See EPILEPSY and APOPLEXY.

Girls, on the approach of the menses, and women who labour under a difficult menstruation, are subject to this disease, which often also attends pregnancy.

Every thing which weakens the constitution renders it more irritable. Among the causes of hysteria, therefore, may be mentioned excessive evacuations, particularly of the catamenia, late hours, depressing passions, continued anxiety, hope delayed, violent excitement, plethora, excess of drinking, &c. The causes of a fit are frequently surprise, apprehension, sudden grief, often indigestion; but the paroxysms occasionally recur without any obvious cause, particularly when occasioned by plethora, which, in a constitution where the balance of the circulation is nicely poised, often occasions convulsive paroxysms. See CONVULSIONS.

During the fit, if the suffocation is violent, pungent acid spirits may be held under the nose, or rubbed round the temples, with moderate frictions about the præcordia, and on the feet. Stools may be procured by a clyster made of an infusion of camomile flowers and common salt, or of two ounces of soap dissolved in a pint and a half of water, if the flatus forcing downwards will admit of their injection; feathers may be burnt under the nose, or cold water dashed in the face. A fit, however, seldom proves fatal; and our chief attention must be directed to the management of the patient in the interval, to prevent a return of the paroxysm. Avoiding the remote causes, whatever they may be, is indispensable; but when owing to plethora, this part of our conduct is involved in difficulties. Bleeding for a time may lessen, but will ultimately increase, plethora; and a sudden abstraction of tension, in any respect, will induce a fit. When stays were worn tight, a delicate woman would often experience an hysteric spasm on taking them off. The regulation of the diet, and of the alvine excretions, are the only prac-

ticable means of obviating plethora: but even this requires delicacy in the conduct, for suddenly abstracting the rich nourishment, to which some hysteric women are accustomed, will produce syncope; and in every case, even the more gradual diminution occasions languor. The same effects follow discharges by stool, if in excess; and in each we must proceed with caution, meeting the inconveniences so far as we can. Obviating the other remote causes requires no particular management.

Our first object in the intervals is to obviate flatulence, which, though a symptom, seems, in some instances, to be a remote cause. For this purpose the fetid gums are highly useful; but opium is a more powerful medicine in this view, and, though in many respects inconvenient, is often indispensable. Where the head is not particularly affected by opiates, or where its exhibition is not followed by sickness and faintness, the only inconvenience resulting from it is producing costiveness. The seeds of the henbane, as we have lately had occasion to mention, unite the advantages of opium without this effect. With opium sometimes camphor may be joined, to correct its bad consequences on the stomach and head; sometimes castor; but there are many habits in which opium, however managed, is injurious. The warmer stimulants act also as carminatives; particularly the aromatics, the bayberries, ether, some of the essential oils, and the animal oil of Dippel.

With a view to correct the constitutional defect tonics of every kind are employed, and particularly such medicines or combinations as are at the same time antispasmodic. The chief of the vegetable tonics is bark, which, alone, proves very generally injurious. With rhubarb and aromatics it is more useful, and with valerian often a very effectual remedy, though too unpleasant to be continued for a long time. The cascarrilla, as less astringent, is less injurious; and the bitters, with aromatics, are often valuable medicines in this complaint. The astringents, as the catechu and alum, are injurious.

Numerous tonics are derived from the mineral kingdom; but the remedy chiefly employed is the steel, and sometimes the zinc. Every preparation of iron has been given in this complaint with equal success, and perhaps there is no real foundation for a preference. The calcined and the vitriolated zinc have been sometimes useful. Copper and silver, in the forms of the cuprum ammoniacale and argentum nitratum, have been rather used as antispasmodics than as tonics, though they seem chiefly useful in the latter view. In general the mineral tonics, particularly the iron, are injurious, when any degree of inflammatory diathesis or plethora is present. See Hoffman and Wallis's Sydenham on the Hysterics; Cullen's First Lines, vol. iv.

HYSTE'RICO HYPOCHONDRI'ÆUS MORBUS. HYSTERICO HYPOCHONDRIAC DISEASE. Authors have usually contended that hysteria and hypochondriasis were the same diseases, differing in the sexes which they attacked; the former particularly affecting women, and the latter men. This, however, was the result of carelessness and inattention. The diseases are peculiarly distinct in every respect; but, like other congenères, though distinct, they may be united in the same individual. Thus the hypochondriac, who always suffers

from flatulence, may be occasionally attacked with true hysteric paroxysms; and the truly hysteric woman may have many of the symptoms of hypochondriasis. These combinations, however, are very rare, and would not have been noticed, but in respect to authors of credit, who have considered them as of more importance than they merit.

We mention this union also with another view. Dr. Wallis, in his publication on Disease and Health, thinks that he has discovered an hysterico hypochondriac disease, and the description he has introduced into the last edition of this dictionary. Nothing could show more clearly the want of discrimination which pervades every page of the former edition than the description of this supposed disease. It differs wholly from both; and is evidently a slow fever, from accumulations in the head, probably joined with acrimony in the fluids. The patient, he remarks, generally broods over some personal, but imaginary calamity. He does the same in nervous fever, in syphilis, and a variety of other diseases: they are not, therefore, to be reduced to hysteria, hypochondriasis, or a combination of both.

In this complaint this author found warm stimulants, a generous diet, with topical discharges from the head, the most useful remedies. They probably would be so, but the complaint is not on this account either of those which are the present objects of our attention.

HYSTERIA CATALEPTICA. A farther investigation of the subject of catalepsy has led us to consider it, with some late respectable authors, as connected with hysteria, or hypochondriasis. It was necessary to point out these connections, though they do not greatly invalidate the former suppositions. The principle still remains of the connection of clonic and tonic spasms; and the disease still depends on a peculiar mobility and

irritability of the nervous system. See Jebb on Paralysis of the lower Extremities; Edinburgh Medical and Surgical Journal, vol. i.; Swedish Memoirs, 1778; Petetin *Electricité Animale*, p. 140.

HYSTERT'IS, (from *hystera*, the womb). See **INFLAMMATIO UTERI**.

HYSTEROCE'LE, (from *κηλη*, a tumour, and *υστερη*, the womb). See **HERNIA UTERI**.

HYSTEROCY'STICA ISCHU'RIA, (from *hystera*, the womb, and *υσθις*, the bladder). A SUPPRESSION OF URINE, from the pressure of the uterus against the neck of the bladder. See **ISCHURIA**.

HYSTEROLO'XIA, (from *hystera*, and *λοξος*, oblique). **OBLIQUITY OF THE WOMB**; a supposed cause of difficult parturition.

HYSTERON, (from *υστερος*, afterwards; so named because it follows the foetus). **AFTER BIRTH**. See **INVOLUCRA**.

HYSTEROPHY'SE, (from *hystera*, the womb, and *φουσα*, flatus). See **PHYSOMETRA**.

HYSTEROPTO'SIS, (from *hystera*, and *πιπλω*, to fall). **Bearing down of the vagina or of the womb**. See **PROCIDENTIA UTERI**, and **VAGINE**.

HYSTEROTO'MIA, (from *υστερα*, the uterus, and *τομος*, a section). See **CÆSAREA SECTIO**.

HYSTRICIASIS, (from *υστριξ*, a hedgehog). A disease in which the hair is said to stand erect like the prickles of a hedgehog. See *Philosophical Transactions*, No. 424.

HYVOU'RAI BRASILIA'NIS. A large tree in America, supposed to be a species of that which produces the guaiacum, as its bark is used in Brasil for the same purposes as we use the guaiacum wood. The name *hyvourahé* signifies, in the Brazilian language, a rare thing. See *Lemery des Drogues*.

I.

I C H

IA'MBLICHI SA'LES; from IAMBlichus, the inventor. A preparation with sal ammoniac, some aromatic ingredients, &c.

IATRALEI'PTES, (from *ιατρος*, a physician, and *αλειψω*, to anoint). A physician who cures diseases by ointments and frictions.

IATROCHY'MICUS, (from *ιατρος*, a physician, and *χυμια*, chemistry). See CHEMIATER.

IATROLI'PTICE. The method of curing disease by unction and friction.

IATROPHY'SICUS. A philosopher who treats of medicine as a branch of philosophy.

I'BA. See ANINGA.

IBE'RIS, (from *Iberia*, where it flourishes). CARDIMANTICA, or SCIATICA CRESSES; *lepidium iberis* Lin. Sp. Pl. 900. See LEPIDIUM and CARDAMINES.

IBE'RIOUS. See LEPIDIUM GRAMINIS FOLIO.

IBIBIRA'BA. A berry-bearing tree in Brasil: a water distilled from its flowers and leaves is used in inflammations of the eyes. See Raii Historia.

IBI'RA. A tree in Brasil, whose fruit, when dried, is used instead of pepper. Neither this nor the former plant is found in the modern systems. See Raii Historia.

IBIRA'CE. See GUAIAACUM.

IBI'RA-PITA'NGA. See LIGNUM BRASILIUM.

IBI'SCUS, HIBISCUS, q. v. MARSH-MALLOW. See ALTHEA, and ALTHEA THEOPHRASTI.

IBI'XUMA, (from *ιξιμος*, the mallow, and *ιξος*, glue; from having a glutinous leaf like the mallow). See SAPONARIA.

ICE, used as a means of abstracting heat in hernia, hæmorrhage, and many other chyrurgical diseases.

I'CHOR; (Greek *ιχωρ*;) sanies; a bloody, thin, but acrid fluid, which distils from wounds.

I'CHITHYA, (from *ιχθυς*, a fish). The name of a hook for extracting the fœtus; from its likeness to a fish hook; or raspings, according to Erotion.

ICHTHYE'MATA. (from *ιχθυα*, the scale of a fish).

I C H

The scales of fishes, and the raspings of the bark of trees.

ICHTHYOCO'LLA, (from *ιχθυς*, fish, and *κολλα*, glue). ISINGLASS; *colla piscium*; *alcanna*; and *huso*; FISH GLUE, is a solid glutinous substance, prepared in Muscovy from the sturgeon. The skins and fins are boiled in water; the decoction is inspissated to a due consistence, and poured out so as to form very thin cakes, which are either dried in that form, or cut while soft into slices, and rolled up into spiral and other shapes. A finer kind is, it is said, prepared by rolling up the air bladders of the accipenser struthio. That which is clear, thin, and almost transparent, is the best. See Philosophical Transactions, vol. lxiii.

It is one of the finest of the animal glues, without smell or taste. When beat into shreds, it readily dissolves in water or milk, forming a mild, nutritious, restorative aliment; as well as a remedy in the fluor albus, continued diarrhœas, and other evacuations from debility. Its solution in water or spirit, if nicely spread upon silk, is an elegant plaster for slight injuries to the skin; and, joined with some resins, it is called *court plaster*. (See EMPL. ADHÆSIVUM NIGRUM.) It is said to agree with the gum tragacanth in medicinal virtues; but, like all other animal mucilages, it soon runs into a state of putrefaction, and becomes more irritating than the vegetable mucilages. Hollow cylinders of isinglass are employed to support the sides of a divided intestine, when united by a suture. A passage is thus left for the contents, which by a solution of the isinglass is gradually enlarged till the wound is healed. See Lewis's *Materia Medica*; Neumann's *Chemical Works*; Cullen's *Materia Medica*.

ICHTHYOSIS, (from *ιχθυα*, the scale of a fish, which it resembles). A harsh, dry, scaly, and almost horny texture of the skin, differing from leprosy by its not falling off in branny scales. Above and below the elbow and knee, Dr. Willan observes, that the scales are small, rounded, and papillary, of a black colour: the

papillæ have short narrow necks, with broad irregular tops. On the rest of the body they are large and imbricated, sometimes divided by whitish furrows. The soles of the feet are dry and rough; the palms of the hands thickened and brittle, with large painful fissures, and the face is covered with bran rather than scales. The inner part of the wrists and hams, the inside of the elbow, and the furrow along each side of the spine, the inner and upper part of the thigh, are usually free. Some perspiration is necessary; and this seems occasionally to produce inflamed pustules. The disease appears to be constitutional, not hereditary. Two cases of a horny ichthyosis impeding the motion of the muscles are described in the 68th volume of the Philosophical Transactions.

ICICA, and ICICA'RIBA. GUM ELEMI. See ELEMI.

ICON. A figure: the abbreviation of icones plantarum, botanical plates.

ICOSANDRIA, (from *εικοσι*, *twenty*, and *ανρ*, *a husband*). The names of the twelfth class of the Linnæan system, comprehending those plants which have hermaphrodite flowers, with twenty or more stamina, growing on the inside of the calyx, not on the receptacle. The situation, and not the number, of stamina is chiefly to be attended to. The calyx is also monophyllous and concave in this class; and the claws of the petals are fixed into the inside of the calyx.

ICTERO'DES, (from *ικτερος*, *the jaundice*). The BILIOUS ARDENT FEVER. See BILIOSA FEBRIS.

ICTERITIA, (from *icterus*, *the jaundice*). DISCOLORATIONS, or diseases which occasion an unusual colour of the whole skin without acute fever.

ICTERUS, (from *ικτερος*, *the golden thrush*, from the complexion of the patient resembling in colour the plumage of that bird. Pliny ridiculously observes, that if the jaundiced person looks on this thrush, the bird dies, and the patient recovers;) the JAUNDICE, *morbus argutus*, *aurigo*, *morbus regius*, *cachexia etterica*, or *icteritia*; by Paracelsus, *leseoli morbus*. It is owing to an obstruction of the discharge of the bile into the bowels, and its return into the blood by the absorbents. Dr. Cullen places this disease in the class *cachexiæ* and order *impetiginæ*; defining it a yellowness of the skin and eyes; white fæces; the urine of a deep red, tinging a white rag of a yellow colour when dipped into it. The species are:

1. ICTERUS CALCULO'SUS, when there is acute pain in the hypogastric region, which increases after eating, and when bilious concretions pass through the intestines.

2. ICTERUS SPASMO'DICUS, without pain, and the yellowness of the skin happening after spasmodic diseases or affections of the mind.

3. ICTERUS HEPATICUS, without pain, following a disease of the liver.

4. ICTERUS GRAVIDARUM, arises during pregnancy, and disappears after delivery.

5. ICTERUS INFANTUM, happens soon after their birth. A yellowness of the skin sometimes arises from a deficiency of the red particles of the blood, or the effusion of the serum. The appearance deceives common observers, but may soon be distinguished by an experienced eye. The yellow tinge of the urine will at once decide any doubt. Infants have a yellowness of ten independent of bile from the red effusion under

the skin, assuming a yellow colour, after being partly absorbed. The true jaundice of infants probably arises from the hardened meconium obstructing the duct.

The genuine jaundice arises from an obstruction of the duct, by gall stones, or viscid bile. Sydenham speaks of a symptomatic jaundice produced by hysteric symptoms; but this complaint is probably the icterus spasmodicus. The yellowness from the bite of a viper is not a species of jaundice. Women are generally more subject to this disease than men, either from a slower action of the intestines or from a more sedentary life.

The cause of the true jaundice is the bile mixing with the blood in consequence of its obstruction from gall stones, spasms, scirrhus, and sometimes even from flatulence or a gravid uterus. A scirrhus liver is the cause of the most fatal kind; and a jaundice is often a mark of a constitution wholly decayed: in such cases the liver is often scirrhus. In a late publication Dr. Gottlieb Richter thinks it probable, that "the most common cause of jaundice is a stimulus or irritation acting upon the hepatic system, which prevents the afflux, secretion, and excretion of the bilious fluids; or, rather so deranges the circulation in the hepatic system, that the several parts do not reach their destined places, according to the laws of health, but are again mixed with the general mass." In proof of which he recites a case of a high degree of jaundice, where no gall bladder was found; but, in its place, only a skinny substance of a very small size, without any cavity. "The whole liver was full of white concretions, apparently of the nature of calcareous earth, of different sizes, from that of a pea to that of a cherry, and which floated in water." In this case, however, though the bile formed was not collected, it was evidently obstructed, and of course absorbed. He confirms his opinion by the authority of Chaux, who, in the seventy-fourth volume of the Journal de Médecine, endeavours to show that the jaundice can be cured by sedatives alone; by that of Selle, who, in his *Medicina Clinica*, p. 292, imputes the jaundice to a stimulus; and of Vogel, who, in his *Treatise on Jaundice*, published at Wetzlar in 1791, has, he thinks, proved in a very convincing manner that the jaundice is occasioned by a state of irritation in the liver. See Richter's *Medical and Surgical Observations*.

These opinions were formerly common, but have long since been rejected; and jaundice is now very generally attributed to obstruction of the bile from the causes which distinguish the species. However, when the jaundice affects the habit, the skin and whites of the eyes are usually yellow, the excrements most frequently white, and the urine deposits a copious dark sediment. Besides these, an inactivity, anxiety, sickness, indigestion, uneasiness, or acute pain, at the pit of the stomach, itching in the skin, and other symptoms, occasionally attend. In general every function is disordered, for the bile mixes in part with every secreted fluid, except, perhaps, the milk; but the principal inconveniences arise from its obstruction, which prevents its action on the stomach and intestines.

When a scirrhus of the liver, or the gall duct, is the cause, a cure can scarcely be expected; and a hæmorrhage, which shows that the blood is both acrid and thin, is highly dangerous. In adults this disorder often

may continue many months without any considerable danger; but, in general, its duration for a long time shows that the obstructing cause is firmly impacted; and the injury which the bile, when again deposited, does to the digestive organs often occasions an incurable dyspepsia, or a chronic debility, with a general dissolution of the fluids. After a fit of jaundice has disappeared, another slight one will often follow, which yields with little difficulty, and the disease is not peculiarly liable again to recur.

During the whole of this disorder the patient should use frequent exercise, but without much fatigue; a warm bath and cheerful company greatly assist the cure: the diet should be attenuating and aperient.

Medicines in this complaint are of doubtful efficacy, and the disease often yields rather to the relaxation of the duct, when the continuance of the stimulus renders it habitual. Stimulating the mouths of the ducts by the most soluble laxative, as soap and the neutrals; compressing the duct by the joint action of the stomach, diaphragm, and abdominal muscles, as in the operation of vomiting; and alternating, with the emetics and cathartics, opiates, often in the most active doses, is the best plan. The operation of vomits has been supposed likely to induce inflammation; this consequence, however, we have never yet found; but should it occur, a large bleeding, with a blister externally, and cooling laxatives, are the best remedies. The castor oil has been preferred in those cases as a laxative, but it seems to possess no peculiar advantage. Mercurials have been lately given in jaundice and in hepatitis, it is said, with success. Calomel is undoubtedly often an useful purgative. The best exercise is riding on horse-back.

If a viscid bile occasion this disorder, which is known by the absence of an acute pain at the pit of the stomach, shooting out from thence to the back, after bleeding, and an emetic, aloetic and mercurial purges are preferable; after these, the kali acetatum is the best remedy, for it hath all the advantages of soap without its disagreeable taste, and is at the same time an useful febrifuge. It may be given to a drachm, or a drachm and a half three times a day.

A redundancy of bile never produces jaundice, for the stools are highly coloured with the bile. In this case, the proper remedies are active purges, particularly the rhubarb and calomel, in doses adapted to the constitution of the patient. Acids and demulcents also contribute to the relief.

When the hæmorrhage is a troublesome symptom, acids and demulcents, the ol. ricini, made into an emulsion, or a decoction of hemp-seed in milk, are the best remedies; and if fever require it, which is scarcely in any instance the case, a little blood may be taken from the arm.

In case of a scirrhus, the extractum cicutæ may be given as an anodyne or palliative, but will do little real service.

As an attenuant, the rubia tinctorum is said to be useful, perhaps because it is yellow; and the waters of Bath and Harrowgate are highly esteemed. Bitters, and even the bile of animals, have been given to supply the place of bile; forgetting that much inconvenience arises from the bile secreted in the stomach when accu-

mulated in the blood. After the disease is removed they may be useful to restore the strength of the stomach. See CALCULUS BILIARIS.

From the idea of jaundice arising from irritation, or spasmodic affections in the hepatic system, small doses of ipecacuanha, tartarized antimony and valerian, asafætida, cataplasms of cicuta and hyoscyamus, with linseed tea for common drink, blisters, locally applied, in case of pain, with opiates, have been severally administered, it is said, with success. See F. Hoffman; Saunders on Bilious Diseases; White on Diseases of the Bile; Huxham de Aere et Morbis Epidemicis, p. 143, &c.; Sydenham; Heberden's Observations in the London Medical Transactions, vol. ii. p. 123; Medical Museum, vol. i.; Cullen's First Lines, vol. iv.; Coe on Biliary Concretions; Maclurg on the Bile.

I'CTERUS A'LBUS. See CHLOROSIS.

ICTHYOSIS, (from *ιχθυσ*, a fish). A species of lepra, in which the eruption appears like the scales of fish. See LEPROA.

I'CTUS, (from *ico*, to strike). A STROKE OF BLOW. It signifies also the pulsation of an artery, and the sting of a bee or any other insect.

I'CTUS SOLA'RIS. A STROKE OF THE SUN; *insolatio*; and by the French *coup de soleil*. A disease arising from too violent an influence of the sun's heat, particularly on the head.

The diagnostics are a violent head ach, a hot dry skin, a redness and heaviness of the eyes, sometimes a continual involuntary motion of the eye lids, a loss of sleep, drowsiness, occasionally with delirium on awakening, a violent fever, faintness, loathing, and thirst.

Persons not accustomed to labour in the sun are sometimes struck by its heat while on journeys, and die on the spot; others fall into a lethargy, or die in a few hours with symptoms of raving madness. If a patient escapes, he is frequently attacked afterwards with violent head aches, which in some instances affect the eye lids greatly. In others a delirium without a fever, gutta serena, &c. are brought on.

In infants this disorder manifests itself by a heavy, deep drowsiness, which continues several days; frequent delirium; by convulsive twitchings, periodical head aches, and frequent vomiting.

The effects of too great a culinary fire are the same with that of the sun; sleeping with the head near the fire hath produced apoplexy during sleep.

The method of cure which has been pursued is the same with that of sanguineous inflammation; bleeding as freely as the strength will admit. The legs, or, if the disorder is violent, the whole body, has then been put into a tepid bath; emollient clysters frequently injected, almond emulsion, lemonade, and similar demulcent cooling fluids, freely drunk: linen cloths wrung out of vinegar and water are also applied on the face and scalp.

Such are the directions usually given. We have, however, great reason to think the nature of the disease has been misunderstood; at least as it occurs in this climate. The affection of the brain appears to us similar to that after concussion, viz. a state of atony from excess of excitement; and the increased action to be of short duration, and inconsiderable in degree. We have seen no instance in which bleeding has been

requisite; and if the slight increased action rendered leeches or blisters necessary, the period in which they were applicable was soon at an end. The vital functions then appeared to be greatly weakened, and tonics of every kind, with the most perfect rest of mind and body, were indispensable. The shock has not been soon recovered, and, for many months, the mind could not be readily exercised, or a close room borne without giddiness and confusion. After some time the cold bath has appeared highly useful; and, during the whole time, the state of the bowels and the diet should be cautiously attended to. See Tissot's Advice.

IDE'US DA'CTYLUS, (from *Mount Ida*, its native place). See PÆONIA.

IDE'A. See OPHIOSCORDON.

IDEA'LES, (from *ιδέα*, an *idea*). A class of diseases consisting in a faulty judgment or alienation of mind.

IDIOPATHEI'A, (from *ιδιό*, peculiar, and *πάθος*, affection). A primary affection of any part; as of the head in lethargy, and the lungs in pleurisy; but when these parts suffer by consent, or from disorders of other parts, they are then said to be affected by sympathy.

IDIOSYNCRASIA, (from *ιδιό*, peculiar, *σύν*, with, and *κράσις*). IDIOSYNCRASY; sometimes also *idiocracy*, *idiotropia*. Every individual hath a state of health peculiar to himself; and different bodies vary from each other, though each may be in a healthy state. This peculiarity of constitution is called *idiosyncrasy*. Idiosyncrasy sometimes depends on the original organization; and diseases from this cause are often incurable. But when they arise from the state of the nervous power, it either respects its mobility or tone, and is shown by some peculiarity in the functions. It may then be readily corrected, if not wholly removed. See HYGIENA.

IDIOTROPIA, (from *ιδιό*, peculiar, and *τροπή*, to *nourish*). See IDIOSYNCRASIA.

I'DOU MOU'LLI. The name of a tall plum tree growing in the East Indies, whose fruit is cooling, and bark useful in many chronic diseases. Its place in the botanic systems is unknown.

IGA'SUR. See NUX VOMICA.

IGBUCAI'NI BRASILIANO'RUM. A tree in Brasil, whose fruit resembles apples, and its kernels are a remedy in dysentery; unknown to modern botanists.

IGNA'ME. See CARA.

I'GNIS, (from the Hebrew term *aesh*). FIRE. Bacon, Boyle, Newton, and their followers, consider fire not as an element but as an adventitious property, resulting from the intestine motion of the smaller particles of matter; and this opinion has been lately revived by Count Rumford and Mr. Davy. On the other hand, Homburg, Boerhaave, Lemery, Lavoisier, and Black, consider fire as a material principle or element. The motion of friction or percussion undoubtedly generates or elicits heat; and, if the supposition of the mere vibration of parts could adequately account for the effects, it would be more simple than to suppose a material substance endued with peculiar properties; for it is still an hypothesis, since we cannot show the existence of fire without combination, and all reasoning by analogy promises very little elucidation of a subject which can only be prosecuted by experimental research. So

far as experiment has extended, the result is in favour of the existence of fire as a distinct body. The reality of fire seems evident, by the power we possess of increasing or diminishing it. In the living human body, whatever increases the quantity of crassamentum in the blood, increases the degree of heat also; as an animal diet, aromatics, sometimes iron, and the mineral acids; but nitre, crude sal ammoniac, carbonic acid gas, seem to diminish it, or at least prevent its evolution. In physics, fire is understood to be that subtle invisible cause by which bodies are expanded or enlarged in bulk, and become hot to the touch; fluids rarefied or converted into vapour; solid bodies fluid, and either dissipated, melted into glass, or scorified. It seems, likewise, to be the chief agent in nature on which animal and vegetable life depend; and without which it does not appear that nature could itself subsist for a single moment. See CALORIC.

It has been doubted whether light is a modification of heat or a distinct principle. The greater number of facts show it to be distinct, and it has been lately supposed from induction, that they are antagonising principles repelling each other. See LUMEN.

Many distempers have been named ignis, or fire, but principally the caustic, or burning fever, which Hippocrates often calls *πυρ*, fire.

I'GNIS CA'LIDUS. A HOT FIRE. A violent inflammation hath been called a gangrene when about to degenerate into it; and has hence received the name of *ignis calidus*.

I'GNIS FRI'GIDUS. A COLD FIRE. A sphacelus; because the parts affected become cold as the surrounding air.

I'GNIS PE'RSICUS. I'GNIS SA'CER. I'GNIS SA'NCTI ANTO'NI. See ERYSIPELAS and HERPES EXEDENS.

I'GNIS SYLVA'TICUS. See IMPETIGINES.

Ignis is also a name of several medicines, as *argentum vivum*; the essential oil that swims on the top of distilled waters, &c.

The chemists use fire in different modes in performing their operations; whence their

I'GNIS SAPI'NTIUM, OR HEAT OF HORSE DUNG.

I'GNIS REVERBERATO'RIOUS. A REVERBERATORY FIRE is made in a furnace covered with a dome, that the heat or the flame may be reverberated on the vessels immediately exposed to it.

I'GNIS RO'TÆ, OR FIRE FOR FUSION. Red hot coals, surrounding the vessel in which the matter is contained.

The chemists formerly regulated their fire by different degrees: the first was scarcely to be perceived; the second was when the heat was manifest, but not sufficient to give pain; the third, when the heat was painful; the fourth, when sufficient to destroy the body; and fifth, when the heat would cause gold to evaporate in fumes. Boerhaave was the first who regulated the heat of fires by means of a thermometer; and when the degrees of heat are mentioned in his writings, they are to be understood according to Fahrenheit's scale.

We have since learnt to regulate the higher degrees of heat, by means of Mr. Wedgewood's thermometer, which enables us to ascertain degrees of temperature so high as 32277° of Fahrenheit, could his scale be

extended so far; but, in electrical and galvanic experiments, we seem to experience a greater degree, since we can produce greater effects than can be attained by any fire; but perhaps some of the power must be attributed to the momentum.

On the contrary side, at 1500° of Fahrenheit, it is supposed no heat exists; but this is necessarily hypothetical, for it cannot be ascertained by experiment.

I'GNIS VI'VENS. See CIRCULATUM.

I'GNIS VOLA'TICUS. See IMPETIGINES.

IGNITIO, (from *ignis, fire*). CALCINING.

I'GNYE, I'GNYS, (from *ιχνεομαι, to suplicate*; because bent in supplication). See POPLES.

IKAN, a root apparently of the orchis tribe, brought from China in pieces somewhat oval and compressed; but we know nothing of the plant which produces it, and little of its nature, which is said to be nutritious.

I'LAPHIS. See BARDANA.

I'LECH, and I'LEI'DOS. A first principle, or elementary air. Paracelsus.

I'LEUM INTESTI'NUM, (from *ειλεω, to turn about*; on account of its many convolutions,) *cilion*; *ilion*; one of the small intestines, immediately following the jejunum. Its convolutions surround those of the jejunum, on the two lateral and inferior sides, and it winds about from the left side by the hypogastrium to the right side, where it terminates in a transverse manner at the fleshy brim of the pelvis, and forms the first of the great intestines, called *cæcum*. Winslow observes, that the ileum is of a paler red than the jejunum. Through the whole length of this intestine it is wide and easily dilatable; but where it enters the colon narrow, and its sides more firm and solid.

In the course of this intestine, the valvulæ conniventes gradually decrease in size and number. When it approaches the cæcum they become longitudinal. In this intestine also, as well as in the jejunum, there are single solitary glands or lacunæ; sometimes clusters of glands called *reticulated*, increasing in number near its extremity, and flatter than in the jejunum. The ileum is more closely tied down than the jejunum, and consequently less capable of dilating. The appendices digitales are denominated from their resembling the finger of a glove, and are little processes sometimes sent off from the jejunum and ilium: they sometimes form hernia.

I'LEUM CRUE'NTUM; described by Hippocrates in his work *De Internis Affectionibus*. In this disease, as well as in the scurvy, the breath is fetid, the gums recede from the teeth, hæmorrhages of the nose and ulcers in the legs occur; but the patient's general health is not greatly injured.

I'LEUS, (from *ileum*), (see ILIACA PASSIO,) is an ancient name for the colic. (See COLICA.) The chief varieties are of colica spasmodica.

I'LEX, (from the Hebrew *alah, or alon*). A tree of the oak kind, of which two species are occasionally noticed, viz. *aquifolium* Lin. Sp. Pl. 181, (see AQUIFOLIUM,) and *quercus ilex* Lin. Sp. Pl. 1420. The SCARLET OAK. Its berries are the CHERMES, q. v.

I'LIA. The plural of *ile*, (from *ειλεω, to turn*). The FLANKS; the space between the lowest of the false ribs and the upper edge of the os ilium on each side; the two divisions of the regio umbilicalis.

ILI'ACA PA'SSIO, (from *ilia, the small guts*). The

ILIAC PASSION, *ileus, convolvulus, contorsio, cileos, chordapsus, volvulus, tormentum*; a disease of the small intestines, generally from spasm: Dr. Cullen considers it synonymous with colica.

Considerable confusion has prevailed in describing the symptoms and cure of iliac passion, from inflammation being often attended with spasm, in consequence of increased sensibility and irritability; as well as from spasm producing inflammation. We shall, in considering this complaint, distinguish it wholly as a spasmodic disease, referring the inflammatory ileus to its proper head, under INFLAMMATION.

The disease is characterised by a violent pain in the abdomen, with an inversion of the peristaltic motion of the bowels, so that their contents are thrown up by vomiting. It is usually an acute disorder, but not essentially inflammatory. We know only of three species. The first consists of spasm from causes of debility. These are, gout, repelled eruptions, narcotic passions, particularly of lead, and the vegetable narcotics. In this case the disease is nearly in cause and cure the same with COLICA PICTONUM, q. v.

The second species is produced by an intromission of the intestine, where a portion of the intestine falls down into the part below, generally doubling the intestine for the space of an inch or more, and thus constricting it. This is occasioned often by spasm, which contracting the diameter of a part of the gut admits of its introduction into that below. To this species the term of the true iliac passion is sometimes confined. Dr. Hunter takes notice of a disease to which children are more particularly subject, because their mesentery, having scarce any fat upon it, easily slips with the gut; and this he calls the *volvulus*, or *volvulus*, of which he observes there are two kinds: the first is when a part of a gut is received into the part next above it; the other is when a part of the gut is received into that below it. The last is, however, by far the most frequent.

The third species is a spasm of the intestines, excited by a mechanical body irritating or obstructing the intestines. A plumb stone or a calculus is of this kind; but the intestinal calculus is very rare in the human species. It will be obvious, however, that the first and third of these species properly belong to colica; nor indeed is it easy to separate these diseases. Much confusion would be avoided by abolishing the term altogether, or by confining it wholly to colic from intromission. The latter, however, is seldom known till after death, and cannot properly form a distinct disease.

A costiveness usually precedes this disorder for some days, and pain is chiefly felt about the navel. With the pains, the belly is gradually inflated, and a hard tumour is felt in the umbilical region, surrounding the belly like a cord: not the least flatulence can for a time pass either upward or downwards. Inflammation, with its worst consequences, rapidly comes on.

The iliac passion should be distinguished from rheumatic pains in the muscles of the abdomen, and from inflammation of the peritoneum. In the first the external soreness is considerable, and the pain in moving the body much greater than in colic, even when inflammation has come on. The same circumstances distinguish peritonitis, and in both free motions do not procure considerable relief.

The cure of iliac passion differs in no respect from that of colic. If it arises from intusussception, we have said that it is seldom known. Practical authors have remarked, that if the gut has fallen into the intestine below, laxatives are injurious, and the cure must be attempted by clysters. The contrary practice is preferred in opposite circumstances. This is, however, a refinement which we cannot apply, as the existence of either is unknown.

Clysters of the fumes of tobacco will, in this species of disease, be particularly useful; and the warm bath is frequently salutary. A blister also to the abdomen, a remedy particularly adapted to INFLAMMATIO INTESTINORUM, q. v. is often useful in this disease.

The prognostics are favourable while inflammation is absent; while clysters can be thrown up, and returned by stool; while the pains shift, and the pain and vomiting occur only at intervals: it is still more promising, if a laxative, taken by the mouth, passes by the anus; but if little or no relief is obtained by stool for some days there is scarcely room for hope—indeed none, unless true feculent matter is copiously discharged. An entire suppression of urine is a dangerous symptom, though some degree of suppression generally attends.

See Hippocrates de Morbis; Aretæus; Cælius Aurelianus; Celsus; F. Hoffman; Sydenham; London Medical Observations and Inquiries, vol. i. p. 223, &c.; Edinburgh Medical Commentaries, vol. ix. p. 266, 278.

ILI'ACA MI'NOR, ARTE'RIA, is the most posterior branch of the hypogastric artery; sometimes the branch of the glutæ.

ILI'ACA VA'SA. The ILIACÆ ARTERIÆ and VENÆ, which see.

ILI'ACÆ ARTE'RIÆ; belonging to the ilia. The ILIAC ARTERIES are formed by the bifurcation of the aorta, at about the fourth vertebra of the loins. They descend nearly three fingers breadth from their origin; and when they arrive at the psoas muscle, on each side, or are upon it, each divides into two, an external and an internal: the external hath no particular name; the internal is called *hypogastrica*. See HYPOGASTRICÆ ARTERIÆ.

The external iliac, on each side, runs down to the ligamentum Fallopii, under which it goes out of the abdomen. In this course, it gives off a few small arteries to the peritonæum, and parts near it; but, as it passes out of the belly, under the ligament, it detaches two considerable branches, one internal, the other external: the inner is called EPIGASTRICA, q. v.; the external, INNOMINATA, q. v. The external iliac also gives off a small branch internally, under the ligament, which runs to the vagina or the spermatic chord, and sometimes another from the outside of the os ilium.

For the internal iliac artery, see HYPOGASTRICÆ ARTERIÆ.

ILI'ACÆ VE'NÆ, (from the same). ILIAC VEINS, *itillares venæ*, are formed by the bifurcation of the vena cava, about the last vertebra of the loins. After their leaving the vena cava, each divides into two principal branches; the iliac externa, or anterior; and the iliac interna, or posterior: the external, which seems the true continuation of the trunk, is sometimes simply named iliac; the internal hypogastrica: each follows the course

of the respective arteries. The external iliac veins lie a little on the inside of the arteries, and, before they leave the abdomen, they accompany their corresponding arteries, both in their course and in their divisions into branches.

ILI'ACUS EXTE'RNUS, MUSCULUS, (from the same). See PYRIFORMIS.

ILI'ACUS INTE'RNUS, MUSCULUS, lies upon the concave part of the ilium, arising likewise from the anterior edge of the bone, and runs down before the psoas muscle: it then runs over the head of the bone, and passes inwards, to be inserted into the little trochanter; lifting, in its action, the thigh upwards.

ILI'ADUM. The three principles of Paracelsus. Sometimes, according to the same author, a mineral spirit, supposed to be contained in every element, and the cause of diseases.

ILIA'STER. The occult virtue of nature, whence all things increase. Paracelsus.

ILINGOS, (from *ιλιγξ*, a vortex). See VERTIGO.

I'LION. See ILEUM INTESTINUM.

I'LIOS. See PASSIO ILIACA.

ILISCUS. Madness occasioned by love. Avicenna.

I'LIIUM, OS; *os innominatum*, but strictly its upper part. Its name is given from its supporting the ilia. The ilium forms the upper and posterior portion of the pelvis, extending to the transverse section of one third of the acetabulum. The external side is convex, called its dorsum; the internal part is its costa; the superior semicircular edge, the spine. The whole cavity is called *cholas*, or *cholago*. Between the os sacrum and the ilium is the sciatic notch, where the sciatic nerve and posterior crural vessels pass without being subject to compression.

ILLÈCE'BRA, (from *ειλεω*, to turn; because its leaves resemble worms,) *vermicularis*, *piper murale*, *sedum minus*. WALL PEPPER and STONE CROP. *Sedum acre* Lin. Sp. Pl. 619; is a very acrid plant, proving violently emetic and cathartic, so that the best authors have thought it unsafe. It has been employed, however, boiled in milk, as an antiscorbutic, and has been occasionally used in epilepsies. When employed in scurvy, a handful is boiled in eight pints of milk to four. Macquer recommends it in scrofulous and cancerous ulcers.

ILLEGITIMUS, (from *in*, and *legitimus*, lawful). ILLEGITIMATE; an epithet for the false ribs, and for some anomalous fevers.

ILLI'NCTUS, (from *illingo*, to lick up). See LINCTUS.

ILLI'SIO, (from *illidor*, to dash against). See ENTHLASIS.

ILLISIO'NES AQUA'RUM. See CATAELYSMUS.

I'LLOS, (from *ειλεω*, to turn round). See OEULUS.

ILLOSIS, (from the same). See STRABISMUS.

ILLUMINA'BILIS LA'PIS, (from *illumino*, to shine). See BONONIENSIS LAPIS.

ILLUTA'TIO, (from *in*, upon, and *lutum*, mud). ILLUTATION; besmearing any part of the body with mud, and renewing it as it grows dry, with the vague or ridiculous view of heating, drying, and discussing. The mud found at the bottom of mineral springs is chiefly employed.

I'LLYS, (from *ειλεω*, to turn round). A person affected with strabismus.

I'LYS, (from *ιλυε*, mud). The FÆCES of WINE;

and an epithet for the sediment in stools and urine, which resembles them.

IMAGINA'RII, (from *imagino, to conceive*). Diseases in which the imagination is principally affected.

IMAGINA'TIO, (from the same). IMAGINATION. To the power of the mother's imagination many peculiarities in the fœtus have been ascribed. See FÆTUS. Philosophical Transactions Abridged, vol. ii. p. 222. Medical Museum, vol. iii. p. 273, &c.

IMBECILLITAS, (from *imbecillis, feeble,*) *acratia* and *arrhostia*, generally means a debilitated state of the habit, and the latter word sometimes implies mental imbecility.

IMBECILLITAS OCULO'RUM. See AMBLYOPIA. NYCTALOPS.

IMBE'RBI, (from *in, not,* and *barba, a beard*). BEARDLESS; botanically it is applied to the corolla.

IMBIBI'TIO, (from *imbibo, to receive into,*) a kind of cohobation, when the liquor ascends and descends upon a solid substance, until combined with it. Sometimes it signifies cohobation, and any kind of impregnation.

IMBRICA'TUS, (from *imbrex, a tile*). The leaves or scales of plants, disposed so as to lie one on the edge of the other, like tiles on a house. The term is applied to leaves, and their serratures in the bud: to the stem, when covered with scales; *tectus ut nudus non appareat*; to the calyx, as in the *hieracium, sonchus*, and other *syngenesia*; to the spike, when the flowers are so close as to press over each other.

IMME'RSIO, (from *immergo, to plunge in*). Chemical immersion is a species of calcination, when a body is immersed in any fluid, to be corroded. When any substance is plunged into a fluid in order to deprive it of a bad quality, or to communicate a good one, the same term is employed.

IMME'RSUS, (from the same). See INFRASCAPULARIS MUSCULUS.

IMPASTA'TIO, (from *in,* and *pasta, paste*). IMPASTATION. The making dry powders into paste by means of some fluid. See INCORPORATIO.

IMPA'TIENS HE'RBA, (from *in,* and *patior, to suffer*, because its leaves recede from the hand with a crackling noise). See MOMORDICA and PERSICARIA SILIQUOSA.

IMPERATO'RIA, (from *impero, to command*, because its leaves extend, and overwhelm the lesser plants which grow near it). MASTERWORT. *Astrantia, magistrantia, ostritium, imperatoria major, astritium, struthium, smyrniom; imperatoria ostruthium* Lin. Sp. Pl. 371.

It is an umbelliferous plant, with large winged leaves, divided into three indented segments, producing thick, oblong, striated seeds, surrounded with a narrow leafy margin: the roots are oblong, thick, knobby, jointed with several lateral fibres, brown on the outside, and whitish within; perennial, a native of the Alps and Pyrenees; found in several places on the banks of the Clyde, in Scotland, by Mr. Lightfoot.

The root is warm, grateful, and aromatic, nearly of the nature of angelica; yielding to water, or spirit of wine, its smell, warmth, pungency, and bitterness. On inspissating the spirituous tincture, very little of its flavour exhales; but nearly the whole is carried off in distillation with water. If the root is held in the mouth it

provokes saliva; if swallowed, purges; and is sometimes called the *countryman's purge*: an infusion of it in water, sweetened with honey, is said to be an expectorant. The roots should be taken up in the middle of the winter of the second year. It was considered as an alexipharmic and sudorific; and in some diseases employed with so much success as to be called *divinum remedium*; but, at present, it ranks only among the inferior aromatics. A name also for ANGELICA.

IMPERATO'RIA NI'GRA. BLACK MASTERWORT, *astrantia nigra, sanicula femina; astrantia major* Lin. Sp. Pl. 339, is kept in the gardens of the curious, and flowers in July. Its black and fibrous roots only are used.

See Raii Historia Plantarum; Lewis's Materia Medica; Neumann's Chemical Works.

IMPERIALIS A'QUA. See FLUOR ALBUS.

IMPETI'GINES, (from *impeto, to infest*). Diseases which occasion blemishes on the skin; *terna, derbia, ignis sylvaticus; volagrius*, or *volaticus*, and *serfigo*. See LEPRO, PRURITUS, HERPES, and MENTAGRA.

In Dr. Cullen's system the impetigines are an order of the *cachexiæ*, defined disorders from a general bad habit, manifesting themselves principally by disfiguring the skin and other external parts of the body. The itch, though affecting the skin, is placed in the class *locales*, since it is unconnected with the general habit.

IMPETI'GO of Celsus, (from the same,) *lepra Græcorum*, Blanchard. In Celsus it is described as consisting of hard dry prurient spots in the face and neck, sometimes over the whole body, disappearing in branny scales.

IMPETI'GO PLI'NI and A'RABUM; the *lichen* of Blanchard.

IMPLU'VIUM, a SHOWER BATH, (from *impluo, to shower upon*). See EMBROCATIO.

IMPOTEN'TIA, (from *in, not,* and *potens, able*). IMPOTENCE in men is the same in its effect as sterility in women, that is, an inability to propagate their species; but in the causes and the circumstances these states greatly differ.

In each case there is a failure of propagation; but, in each, there is by no means an unfitness for the venereal act. Sterility in women, indeed, often arises, like impotence in men, from a coldness of constitution, which admits not of due excitement; but it is also owing to the causes which separate the fœtus almost as soon as formed. From men who are impotent no impregnation takes place.

The great causes of impotence in men are organic defects and debility. We have shown, that in generation the semen must be carried to the uterus, and probably to the Fallopian tube; but in this ultimate destination it is apparently assisted by the action of the womb itself. To carry it to this organ requires a free passage through the urethra, no inconsiderable activity in the ejaculatory muscles, and the full distention of the corpora cavernosa. The free passage is sometimes prevented by strictures in the urethra, and sometimes, as in a case recorded by Petit, by a faulty direction of the orifices through which the semen passes. A natural phymosis has been found also an obstruction to the free discharge of the seminal fluid. A severe priapism seems occasionally to constrict the cavity of the urethra, or of the entrance of the vasa deferentia; for in this disease there is no emission, and the feelings are those of

violent pain rather than of pleasure. Intoxication, in some men, will produce this violent spasm, and unfit them for the completion of the venereal act. See **PRIAPISMUS**.

Debility, however, from too frequent or unnatural indulgences, is the most common cause, shown by an imperfect erection of the penis, or too weak a discharge of the semen: the latter is often a consequence of the former. In some weak habits the discharge immediately follows the slightest irritation, either of the parts or of the mind. Dreams so imperfect as scarcely to be remembered will occasion it, and this arises from the increase of irritability, in consequence of debility. From its remote cause, tonics, and the most stimulant nutriments, are employed; but the only remedies are those which lessen irritability, viz. camphor, opium, and hembane, or hemlock. Washing the penis and scrotum, morning and evening, with cold water, and dashing the water against these parts from a bidet, are often useful; but it is necessary to remove every alluring or enticing object; to guard against every lascivious thought. When impotence arises from so great a debility as to admit of the discharge of semen by the efforts to relieve the belly, the strongest tonics and astringents are required.

It has been supposed by some authors, that, in such cases, the semen wants its usual stimulating properties, as it is observed to be unusually fluid; but of this there is no evidence; and, as the discharge is so readily excited, we think it more probable that its fluidity depends on its not being allowed to stagnate.

Mr. Hunter has, we think, refined unnecessarily on this subject, by stating one cause of impotence to be a want of correspondence in the successive actions of secretion and discharge. If the first is too rapid for that erected state of the penis which renders the ejaculation effectual, it constitutes this disease as certainly as when the action of the muscles of the latter is too quick for the former. Debility, and its consequent state of irritability, are sufficient to explain all the circumstances of the case without such recondite researches. In general, where there are corresponding actions of two connected parts, it is very unusual to find them separated. Each may be weakened; but from habit each will partake of the disease, and will act together as before, but with diminished power.

A singular cause of impotency is recorded in the Medical Essays of Edinburgh, where each attempt was followed by an epileptic paroxysm. From what has been said on that disease, it will not be surprising, that, in a mobile habit, disposed to convulsions, a stimulus so violent should bring on a paroxysm. The reasoning and the cure were equally ridiculous; nor is this a single specimen where physicians have succeeded by accident, and have really taken a readier road for the relief of the diseased than they themselves suspected.

The state of the mind, it is observed, has a considerable influence on the powers of the body, particularly in the venereal act. The body, Mr. Hunter remarks, should not only be in a state of health, but the mind free from apprehensions, anxiety, and distress. The mere anxiety of excelling in this act has been no uncommon cause of disappointment. A state of hope, a consciousness of crime, a recollection of former failures, equally enervate the body. Such causes of impotence are to be clearly distinguished from real defects, since an alteration in

circumstances, by which anxiety, distress, &c. are removed, will relieve the complaint. Greater confidence, from having once succeeded, will alone break the charm, and all will be well.

The mind is more intimately connected with the genital system, chiefly in men, though in a certain degree in the other sex, than has been imagined. The apprehension of weakness, in this most important of functions, really produces it. The imagination broods over fancied ills, till the whole system is really disordered. In this state every wall offers a certain remedy, and the *Solar Tincture*, the *Restorative Drops*, are eagerly bought. It is remarkable, that these diseases are distinguished by capitals to lure the unwary; but the medicines are sometimes truly restorative, for they restore confidence, and thus contribute to remove the disease. In general, however, each quack is tried in succession, till tired nature decays into a hectic, is overwhelmed in a dropsy, or the mind, sinking in imbecility, or mania, offers a melancholy spectacle of what degradation human nature can suffer. All this distress might be removed if the patient had the resolution to tell his grief to a friend, or a physician of character and judgment. A well regulated plan of medicine and diet would contribute to relieve the bodily complaint, while the mind, consoled with prospects of returning health, would assist in realizing the prediction. Many such instances we have known where the disease has been radically removed, and the desponding patient become a happy husband, and the delighted father of a numerous and healthy offspring.

We have so mixed the medical directions with the descriptions of the disease, that we have little to add on this part of the subject. We may, however, again repeat, that, except in impotence from great relaxation, tonics and astringents are of little avail. Where it arises from too great irritability, a cooling diet, abstaining from lascivious thoughts or objects, with sedatives, are the best remedies. In that case, which arose from epileptic paroxysms, the cure was effected by rendering the object of desire more familiar before the act was again repeated, and, of course, lessening the too violent stimulus. There is no opinion more inconvenient in its effects than that which dictates a full, nutritious, and stimulant diet. We have often had occasion to repeat, that no cause of weakness is so frequent and obstinate as that which arises from fulness of the circulating system, and no plan of medicine more injurious than constringing over distended vessels by tonics. It has been supposed that some medicines have a peculiar effect on the genital system; and the balsams have been given, as they are directed to the bladder, and, of course, may communicate a stimulus to the neighbouring parts. We have not found them particularly advantageous; and even the balsam of Peru, which unites a tonic with its stimulant power, has not produced any very salutary effect. If, as we have been informed, Geneva is not favourable to the active energy of these organs, we can hardly expect great advantage from medicines so nearly resembling this spirit. In every case, except where the fulness is considerable, cold bathing, both general and topical, is highly useful.

To abstain from, or to indulge, venereal pleasures, is equally injurious. A moderate use is salutary; and marriage, if the disease be not too far advanced, is to

be advised. It has often succeeded; and when the confidence that the power is not wholly lost be once established, the power itself is soon regained.

IMPREGNATIO, (from *imprægnor*, to conceive). **IMPREGNATION**. *Ingravidatio*. The state immediately after conception, continuing till delivery. A woman usually perceives the child to move at different periods; the soonest at the end of forty days, the latest at the end of five months. But some women, without being pregnant, perceive a motion like that of a child. La Motte thinks that a large child and a small quantity of water may prevent a pregnant woman from perceiving the motion of the child. (See **GENERATIO** and **CONCEPTIO**.) For the impregnation of plants, see **FARINA FÆCUNDANS**.

IMPRESSIO, (from *imprimō*, to press upon). See **DEPRESSIO**.

IMUS VENTER, (the lower belly). See **ABDOMEN** and **HYPOGASTRIUM**.

INATA GUACU'IBA. See **PALMA COCCIFERA**.

INCANTAME'NTA, (from *incanto*, to charm). See **AMULETA**.

INCANUS, (from *in*, and *canus*, white, hoary). The leaf of a plant covered with whitish down.

INCARNATIO, (from *incarno*, to bring flesh upon). Medicines which assist the filling up wounds or ulcers with flesh. See **ANAPLEROTICA**.

INCE'NDIUM, and **INCE'NSIO**, (from *incendo*, to burn). A BURNING FEVER; burning heat; sometimes a hot inflammatory tumour.

INCERATIO, (from *in*, and *cera*, wax). **INCERATION**; the reduction of any dry substance to the consistence of wax, by the gradual admixture of oil.

INCERNICULUM, (from *incerno*, to sift) A STRAINER OR SIEVE. In anatomy it means the pelvis of the kidney.

INCIDENTIA, (from *incido*, to cut). Medicines which divide the particles of fluids, supposed to cohere preternaturally, and induce disease.

INCINERATIO, (from *incinero*, to reduce to ashes). **INCINERATION**; *æstiphara*. Reducing any body to ashes by fire. See **CALCINATIO**.

INCISIO, (from *incido*, to cut). **INCISION**. The opening of abscesses by means of a lancet or scalpel. For the best modes of opening them, or extracting matter with the most ease and security, see Bell on Ulcers, edit. 4. p. 76, &c.

INCISORES DENTES, CUTTERS, (from *incidere*, to cut). A name of the four anterior teeth in each jaw from their use in cutting, *Ctenes*, *dentes lactei*, *risorii*, *dichasteres*. The edges of the incisores, by use and friction, are blunt and thicker; though, from the form of the jaw, and direction of the teeth, they sometimes seem to sharpen each other, and become thinner. These teeth are convex externally, and concave internally; so that when they are worn, the internal concave surface of the upper ones, and the external convex surface of the lower ones, are wasted. See **DENS**.

INCISORII DUCTUS; two canals from the bottom of the internal nares, across the arch of the palate, which open behind the first and largest of the *dentes incisorii*; their lower orifices are in the foramen palatinum anterius, called *nasopalatini ductus*.

INCISORII INFERIORES COWPERI MUSCULI, arise from

the alveoli of the lateral incisores of the lower jaw, and are inserted into the middle of the semi-orbicularis of the lower lip.

INCISORII LATERALES MUSCULI. *Canini minores*. A biceps muscle, which unites at the other extremity. It arises from the os maxillare, below the middle tendon of the orbicularis palpebrarum, and below the edge of the orbit in the os maxillare, near the union of this bone with the os malæ; the heads from each side unite about the lateral *dentes incisorii*.

INCISORII MEDII MUSCULI; *incisorii minores Cowperi*, or *incisores minores superiores*; are two small short muscles situated near each other below the septum narium: they rise from the os maxillare, on the alveoli of the first *incisores*, and are inserted into the middle and upper part of the upper lip.

INCISORIUM, (from *incido*, to cut). A table whereon a patient is laid in order to have an incision made on any part; or a body to be dissected.

INCISORIUM FORAMEN, lies behind the *dentes incisores* of the upper jaw, which divides into two, as it opens into the nose on each side of the septum nasi.

INCISUS, (from *incido*, to cut). A leaf whose edge is notched.

INCITABILITAS, (from *incito*, to stir up to action,) **INCITABILITY**. In a practical view it has appeared necessary to make a distinction between this term and **IRRITABILITY**; because, though it is allowed that to those two powers the existence of a machine in a living state, and the action of its moving solids with respect to their continuance, are entirely owing; yet they do in some degree certainly exist independent of each other. By this knowledge, therefore, it is supposed that we shall sometimes be able to explain the different appearances of diseases, and the means of relieving them by medicines directed to either. By **incitability** is meant that power in the brain and nervous system, which may be excited to action by mental affections, as well as local irritation, and which produces those affections we call sympathy; by **irritability**, that power which may be put into action by material stimulus, locally exerted, yet is obedient to the influence of the nerves in general, and cannot in the living machine exist for any considerable time without this union. More strictly, **incitability** is confined to the nervous, and **irritability** to the moving fibres. See Wallis on Health and Disease; **IRRITABILITAS** and **SENSIBILITAS**.

INCLINATUS, (from *inclino*, to bend down,) an epithet applied to a root of a plant which runs obliquely.

INCLUDENS, (from *includo*, to shut up). The calyx of a flower which shuts up and conceals the corolla.

INCLUSUS, (from the same). The stamen of a flower when shut up in the corolla.

INCONTINENTIA, (from *in*, not, and *contineo*, to contain). **INCONTINENCE**. An inability in any of the organs of the human body to retain their contents, which are usually discharged by the exertion of volition.

INCORPORATIO, (from *incorporo*, to blend together). **INCORPORATION**. The union of oily or terebinthinate substances with water into one uniform fluid, by the mediation of a third substance.

INCRASSANTIA, (from *incrasso*, to make thick,) 5 I 2

psycnotica. INCRASSATING MEDICINES; such as reduce the blood and secreted fluids to a proper consistence when supposed to be too fluid.

INCRASSATUS, (from the same). The epithet of a stalk which increases in thickness as it approaches the flower.

INCRUSTA'TIO, (from *incrusto*, to harden). INCORUSTATION; forming a crust or eschar upon any wound.

INCUBUS. The NIGHT-MARE; (from *incubo*, to lie on; *ephiates*, from *εφαλλομαι*, to leap upon; *epibole*, from *επιβαλλω*, to press on; because the patient imagines that something leaps or presses upon him; and *babuzicarius*, from *βαβουζω*, to speak inarticulately, because, in his distress, he mutters indistinctly). There is also a species called *succubus*. The INCUBUS is synonymous with *oneirodynia* in Dr. Cullen's system.

This complaint always happens during sleep: the patient suddenly feels a sense of weight, a dread of suffocation, an oppression as from somebody falling upon him, with an intent to deprive him of life, not suffering him to cry out; hence it is usual with these patients to start up and exclaim with a confused inarticulate voice: they move with difficulty, but, on the first motion, the distressing feelings vanish.

This disorder hath been supposed to proceed from a stagnation of blood in the brain and lungs; but it is a nervous affection, chiefly from indigestion: and those whose nerves are weak, who lead sedentary lives, feed heartily, and sup late, are the most subject to it. Wind is a frequent cause: deep thought, anxiety, or any oppression of mind, equally produces it. It is said that none are attacked with the ephialtes but when laid on their backs. A sense of suffocation, rousing the patient from sleep, has been styled an ephialtic symptom, distinguishing hydrothorax; but, in this case, there is no sense of a heavy weight on the præcordia.

If the patient hath a sanguine plethora, bleeding, a spare diet, aloetic purges, relieve the complaint. Dr. Whytt says that he generally found a glass of brandy, if taken at bed time, would prevent the attack. A slight supper, cheerfulness before bed time, due exercise during the day, are the best remedies; but if these fail, the fetid gums, with camphor joined to opium, at bed time, will succeed.

See Cœlius Aurelianus de Morbis Chronicis, lib. i. cap. 3. Lommii Observaciones Medicinales, iii. P. Egineta, lib. iii. c. 15. Soranus's Aitiologoumena.

INCUMBENS, (from *incumbo*, to lean against,) a term in botany.

INCURVATUS, (from *incurvo*, to bend). Bent, a term applied to a gibbous spine, and in botany to the stalk.

INCUS, (from *incudo*, to strike upon). The ANVIL. The name of one of the bones in the ear; named from its resemblance to an anvil. It is broader than it is thick; articulated with the malleus, behind the manubrium, from whence a short thick process projects backwards, and a long one downwards, which runs down parallel to the long process of the malleus, but rather more backward. The short process is thick at its beginning, but ends in a point, which is turned backwards, and joined to the edge of the opening of the cellula mastoideæ. The long process at its extremity is

rather bent inwards, by which we may distinguish the incus of one ear from that of the other; for, turning the short process backwards, and the long process downwards, if the bending in of the long leg be towards the left hand, it belongs to the right ear, and *vice versa*. See AURIS.

INDEX, (from *indico*, to point out). See DIGITUS. INDIE ORIENTALIS RADIX GENUINA. See GENSING.

INDIANA RA'DIX, from the West Indies, its native place. See IPECACUANHA.

INDICA'TIO, (from *endico*, to show, or point out). INDICATION; *delatio, endeixis*. The diagnostics of a disease, and its pathognomonic signs, are collections of particulars that occur to observation. Indications are conclusions that arise from reasoning on these particulars, called signs. The indication of cure, in all diseases, is to remove the proximate or immediate cause; but this is seldom known.

INDICA'TOR, (from the same). See EXTENSOR INDICIS.

INDICON. See MYRTIDANON.

INDICUM, (from the Arabic term *hindi*, India). THE INDIGO BLUE PLANT; also called *indigo, anil, nil, isatis*, and *coronilla Indica, emerus Americanus, glastum Indicum, Ameri, coachira Indorum, colutea Indica, herbacea, enger, gali, herba de anil Lusitanis, hin-awaru; Indigofera tinctoria* Lin. Sp. Pl. 1061, is a native of South Carolina, but was known to the ancients. It seems to have been indigenous in Malta, and was certainly produced in large quantities in Egypt; and the name *anil* (al-nil) seems to show that it was known to the Arabians. It requires a tropical temperature, but is found within forty degrees on each side of the equator. We are now supplied from the continent and islands of America, though some indigo is prepared in France. This substance is a fæcula, or starch, separated from the plant by the powerful action of fermentation. It is not agreed how far this process should proceed. It certainly goes beyond the spirituous, since ammoniacal salts are found in indigo, but, by complete putrefaction, it is spoiled. Some oil is used in the preparation, though with no very decided object. We suspect its chief advantage to arise from its power of moderating the too violent fermentation, or preventing the escape of the carbonic acid gas. Various species of this plant, and various processes for separating the fæcula, are employed, which it is not our object to detail. It is brought to us in flat cakes of a moderate thickness, moderately hard, of a deep violet colour: the best kind swims on water, and when broken hath no white spots in it. That which is reddish, on being rubbed with the nail, and hath dust and broken pieces in it, is far inferior. Such white spots are found in the common indigo of the shops, which is an adulteration of the genuine kind by the mixture of flour.

The plant is said to be detergent, of some use when applied to ulcers, or to kill lice.

There is another plant which is called *anil*, used by way of decoction in nephritic colics, and suppressions of urine; but we have not been able to determine the species.

See Raii Historia Plantarum. Neumann's Chem. Works.

I'NDICUM BA'LSANUM. See PERUVIANUM BALSANUM.

I'NDICUM LI'GNUM MONTA'NUM. See CAMPECHENSE LIGNUM.

I'NDICUS. See COSTUS.

I'NDIGA SPU'RIA. See COLINIL.

INDIGE'NI, INDIGENOUS; natives of the country in which they are found. The term is applied to plants and animals.

INDIGES'TIO. See DIGESTIO, APEPSIA, and DYSPEPSIA.

INDIGNATO'RIOUS MU'SCULUS, (from *indignor, to scorn*; because this muscle assists in producing a scornful look). See ABDUCTOR OCULI.

I'NDIGO. See INDICUM.

INDU'SIUM, (from *induo, to put on*). A SHIRT or SHIFT. Clean linen promotes perspiration, and it may be renewed as often as the patient pleases, whether the disorder be of the acute or the chronic kind; except during a crisis in fevers, while the patient is in a sweat. Yet, even in this state, with proper precautions, the linen may be sometimes safely changed. See AMNION.

INEBRIA'TIA. We have anticipated the more important observations on this class of medicines in our article ANODYNA, q. v. and we shall now only point out the more common inebriants, with some remarks on their action, for which our readers were not at that time prepared. The most common inebriant is OPIUM. It is employed among the eastern nations, very generally, to procure, not sleep, but serenity and cheerfulness; and its use, in this respect, may be traced to the earliest ages, for it was probably the nepenthe of Homer. TEA is equally general in the west, and in its native country, China, but it is mild in its effects, and, if not drunk unusually strong, or in too copious draughts, it is not injurious. There is some reason to suspect that the additions, which give it the flavour, are most hurtful; for the finest teas produce the worst effects. The BANGUE of the east, prepared from the leaves of the *canabis indica*, and not from those of the *hibiscus abelmoschus*, as has been asserted, is in general use (vide in verbo) in India, as an inebriant; but the BETLE, q. v. is rather a stimulant than a narcotic. The ASSYRIAN RUE, *peganum harmala* of Linnæus, was formerly used, as Bellonius informs us, for this purpose; but its very offensive and disagreeable smell prevents it from being any longer a luxury. The seeds of different species of *datura* have been also used to inebriate, as well as the roots of the black henbane, and the *hyoscyamus, physaloides* Lin. The Delectarians employ the leaves of the *millefolium* to increase the intoxicating power of the beer; and the porter brewers of this country are said to use the *canabis indicus* and the *cocculus indicus*; but this has lately been denied on oath in the King's Bench. Tobacco; the darnel; the clary; the vanilloes; the hemlock; the spawn of the barbel; and the *agaricus muscarius*, have been all employed for this purpose. Fermented liquors and spirits are sufficiently known. See Linnæi *Amœnitates Academicæ Inebriantia*, vol. vi.

All these medicines are sedative, and their effects on the nervous system are to produce an unequal excitement. We have explained, in a variety of articles (see INSOMNIA), that the regular discharge of the mental functions depends on a free, uninterrupted communication between the different portions of the brain.

When from any cause this is prevented, delirium, in different degrees, takes place. If unequally excited, the delirium is of the violent kind: if unequally depressed, of the low, and often of the pleasing kind. Whether pleasing or otherwise, the effect is nearly similar, since the same medicine, in different constitutions, will excite the most soothing and the most horrible images. See MATERIA MEDICA.

INERMIS, (from *in, non*, and *arma, arms*). HARMLESS; applied to soft thorns, as those of the thistle.

INERTIÆ VIS, (from *iners, sluggish*). The power of inactivity. By this, apparently contradictory term, sir Isaac Newton means that passive principle in matter, by which bodies resist any change or alteration of their state, whatever it be, of rest, motion, or its direction; and this resistance, always equal in the same body, is, in different bodies, proportional to the quantity of matter they contain. Hence, in medicine, it means when the powers of the constitution are torpid or inert, and make no effort in the recovery of health.

INFANS, (*à non fando, from its inability to talk*). AN INFANT or CHILD. Fred. Hoffman limits the period of infancy to the time when children begin to talk, and that of childhood to the age of puberty.

During infancy the parts are disproportioned, and the organs, from weakness, incapable of those functions which, in future life, they are designed to perform. The head, the liver, and pancreas, are much larger, in proportion, than in advanced periods; and their secretions more copious. The bile is very inert; the heart is stronger and larger than in future life; the arteries fuller and more active; the quantity of blood sent through the heart of an infant, in a given time, is also more in proportion than that in adults. Though these circumstances are not without utility and subservient to the growing state, yet the imperfection attending them subjects this period of life to many injuries and dangers, from which a more perfect state is exempted.

Infants are more acutely sensible and more irritable than adults; and the diagnostics of diseases are consequently more uncertain. However, no very great embarrassment arises from these circumstances; for the disorders of infants are usually acute, less complicated than those of adults, and are more easily discovered than is generally apprehended.

The vigour of children's constitutions depends greatly on that of their mothers. Healthy women, who accustom themselves to exercise and air, and whose diet is firm and invigorating, alone bring forth children perfectly healthy.

As soon as a child is born, the mucus with which its body is covered is best washed off with soap and water. But the anxiety to render the infant perfectly clean produces inflammation, and considerable uneasiness; moderate cleanliness is at the first sufficient: and the next dressing will easily and safely complete the whole.

After examining the new born infants with a view to discover any accidental injury, or natural imperfection, wrap the navel string in a rag, sufficiently folded, to prevent its coldness from producing inconvenience. The heads of infants should be dressed loosely, and their future formation left to nature.

It was usual after dressing to give oil of almonds, with syrup of violets; sugar with butter, or other

slight laxatives, to discharge the meconium. These are at least useless. A little gruel with milk will alone bring it off; and the first milk of the mother will complete the necessary discharges. For this purpose the child is put early to the breast, usually within twelve hours, which solicits the secretion, and prevents its too violent current.

The general management of the infant state is directed too frequently by fashion, or rather by caprice. Modes and medicines used for centuries, handed down in successive generations, cannot always be combated by reason, but are sometimes wholly exploded by a fashionable physician, who aims at distinction by total overthrow of what has been long held sacred. Common sense must at last decide, and without engaging in controversy, we shall pursue its dictates.

The little being, when first introduced to this world, is brought from a temperature of at least 96°, and should therefore be cautiously guarded against sudden exposure to the air. His clothing should be light and easy; and, at first, warm. The tender skin would be chafed with flannel, and therefore old linen is preferred. Calico would be still better; but the whole must be covered with flannel, and fastened as much as possible by strings. For a long time cold excites uneasy sensations, and he is properly placed close to the mother; by her side, or that of a healthy nurse, he should lie till at least he has lived twelve months; but modern refinement, or modern apprehensions, place him alone in a crib by the side of the bed. On this subject we can only observe, that we have known infants, thus separated from the warm bosom, cry nearly a whole night; and, in general, they *increase slowly*, are weak and delicate, while those with a nurse, if not the mother, have appeared thriving and happy. But, though the child should be kept warm, the air around should circulate freely. A curtain against its head may prevent the current passing over him, but no other curtain should be drawn, and the room should be high, large, and airy.

On the food of children we cannot add to what we have said in the article *ABLACTATIO*; but may here remark, in opposition to a common and most ridiculous practice, that a child should not be accustomed to take its food at distant intervals. Digestion in children is rapid; and, if food is delayed, the child is uneasy; and, when brought, takes it greedily and too copiously.

A healthy child scarcely ever cries. This position will, we know, be disputed; and a child is said to be peevish, fretful, and uneasy, when the nurse is careless and inattentive. Dispositions undoubtedly differ; but the parent, who finds a child constantly crying, should suspect her nurse, and even herself. One cause of this fretfulness is the opinion that the nurse knows when the child should sleep, or eat, better than itself. It is forced to feed when not hungry, and to sleep when eager for play or amusement. We have often cured this disease, by correcting the attendant. It indeed happens that some children will not sleep by night, but even this may be conquered by management; for the healthy child may be amused during the day, and his amusements may be gradually protracted till night approaches. Disposition and fancies show themselves very early to the attentive observer; and, when reason has not yet attained its power, to correct them with violence, irritates without amending. Even at an early

age, children may be soothed into regularity and obedience: they cannot be forced. If a child screams suddenly, he is undoubtedly ill, and should be carefully attended to.

A healthy infant is fond of exercise. He should be moved gently up and down, but without any shocks. On this account the modern cot is preferable to the cradle, for the child may be shook by the latter into a stupor, which a nurse will take care to do, as it saves her the trouble of attending to the infant's play. In dandling the child, great inconveniences arise from compressing the breast. The child sits on the left hand, and, to prevent accidents, leans forward against the right placed on its breast. If the nurse is timid, or if the child starts, the only security is to clasp the breast, by which the ribs are often compressed. If, however, the right hand is placed under the arm, with the thumb over the shoulder, an active child may even start from the other hand without danger. The right hand will support it, or convey it gently to the ground. Swinging seems to give children an uneasy feeling, and even being carried quickly down stairs will make them shrink to the nurse's breast. This is almost the only instinctive feeling that, after much observation of children, has occurred to us. Gentle friction is an excellent addition to exercise, and peculiarly grateful to infants.

The pathology of the infant state is slight and simple. From the disproportioned size of the head, accumulations in this organ are frequent, and almost every fever is attended with a considerable load in the brain. The only peculiar disease of the head is hydrocephalus, though apoplexy and palsy have, at times, attended the infant state. A great difficulty arises in distinguishing the accumulation of water from fever. This is not, indeed, easy, but often unnecessary, since the treatment does not greatly differ; free evacuations from the bowels being equally indispensable in both. Accumulations in the stomach and intestines are the great source of children's complaints. A considerable quantity of mucus is a part almost of their constitution, and it is this accumulation which occasions worms, diarrhoeas, and convulsions. Emetics and cathartics are, therefore, the chief remedies, and the most active drastics are borne with ease, and even advantage. A child may more safely take five grains of calomel than an adult; and often two or three grains of gutta gamba will not produce a considerable discharge. Suffocation, considered as the disease of children, is, we fear, always the creature of art, the effect of indulgence arising from too great warmth, and more frequently from fulness.

The prophylactic management of children is not a very abstruse subject. Early hours, moderate warmth, exercise in the open air, to as great a degree as their strength admits, with a proper attention to their diet (see *DIÆTA*), and the due regulation of the alvine discharges, comprise the whole. The medicines for children should be few and simple. Their stomachs abound with acids, which change the bile to a green colour, and thus tinges the stools with the same hue. The anxious parent, on this appearance, flies to absorbents; but, while the child continues lively and cheerful, and the stools are neither too copious nor too few, no remedy is necessary. In early infancy a child has generally

from three to five motions in twenty-four hours. This number lessens; and, at the age of two years, there are seldom more than two daily. Constitutions differ in this respect, and we have known an infant continue in perfect health with one motion only in twenty-four hours.

See Percival's Essays, Medical and Experimental, ed. 2. p. 363—367; Armstrong on the Management and Diseases of Children. Cadogan's Essay on the Management of Children. Harris on the Diseases of Children, translated by Martin. Clark's Directions for the Management of Children. Moss on Nursing.

INFECTIO, (from *inficio*, to infect). See CONTAGIO.

INFELIX LIGNUM. See SAMBUCUS.

INFERNALIS LA'PIS, (from its burning and destructive property). Caustic made by evaporating strong soap leys almost to dryness. See CAUSTICUM COMMUNE FORTIUS. It is sometimes used instead of the causticum lunare, and often is distinguished by the same name. See ARGENTUM.

INFERUS, (from *infra*, beneath). Situated beneath another part.

—INFIBULA'TIO, (from *infibulo*, to button together). INFIBULATION. This operation is the reverse of circumcision; for it confines the prepuce over the glans penis, to prevent its being drawn back. That part of the prepuce which extends beyond the glans is perforated by a needle armed with a waxed thread, which is moved backward and forward every day until a cicatrix is formed. After this the fibula is fixed.

The ancient Romans thus used to prevent in their singing boys premature venery, to preserve their voices. See Celsus, lib. vii. cap. xxv. The fibula seems to have been a kind of ring.

INFLAMMA'TIO, (from *inflammo*, to burn,) *Phlegmone*; *Phlogosis*; INFLAMMATION. *Phlegma*, Hippocrates; *oxyphlegmasia*; a topical pain, with an injury of the functions of an internal organ, attended with inflammatory fever, and the appearance of a buffy coat on the blood. External inflammation is characterised by a redness, heat, and a painful tension of the affected part.

The most obvious idea which the symptoms of inflammation suggest, is that of an accumulation of blood in the vessels, and its confinement in a given part. The conclusion, however, is too general; for the veins of the part are often swollen, and the secretions from the neighbouring glands sometimes increased in quantity. The accumulation has, however, suggested the idea of its arising from a stimulus, and the confinement of the fluids in the part the idea of obstruction. It is obvious, that a stimulus will produce inflammation; but when this is removed, the inflammation ceases. Obstruction then has been the leading principle in every theory of inflammation, especially when pathologists had remarked, that obstruction alone excites the action of the vascular system.

The source of this obstruction has differed according to the fancy of the enquirer. It was first supposed to be too great viscosity of the blood, and we were triumphantly shown the dense buffy coat on its surface, when drawn; but we now know, that the whole mass of the crassamentum is not preternaturally dense or viscid, for that the basis of the clot is loose in proportion to the

density of the surface. Another opinion was, that, as there appeared to be a series of vessels of decreasing diameters, and evidently some into which the red globules were unable to enter from their size, inflammation might consist in these globules being impelled into vessels not adapted for them, where they were confined, occasioning, from their obstruction, inflammations. This is the famous *error loci* of Boerhaave, and there is no doubt of this "error" taking place; but we shall find it to be an effect, not a cause. Dr. Cullen considers the obstruction as owing to spasm. "That a spasm of the extreme vessels takes place in inflammation is presumed, he observes, from what is at the same time the state of the whole arterial system. In all considerable inflammations, though arising in one part only, an affection is communicated to the whole system; in consequence of which, an inflammation is readily produced in other parts besides that first affected. This general affection is well known to physicians under the name of *diathesis phlogistica*. It most commonly appears in persons of the most rigid fibres; is often manifestly induced by the tonic or astringent power of cold; increased by all tonic and stimulant powers applied to the body; always attended by a hardness of the pulse; and most effectually taken off by the relaxing power of blood letting. From these circumstances it is probable, that the diathesis phlogistica consists in an increased tone, or contractility, and perhaps contraction, of the muscular fibres of the whole arterial system."

Thus rested the state of opinions for many years, when a new opinion arose in the school of Edinburgh; an opinion, however, of private teachers rather than of the professors, that inflammation was owing to a debility of the vessels of the part affected, admitting of considerable distention; or, at least, to a disturbance of the balance between the action of the larger vessels and that of the capillaries, in which inflammation is seated. This opinion has been published by Dr. Wilson, in his third volume on Febrile Diseases, and attributed to Dr. Lubbock, or a Mr. Allen, who, we believe, gave a course of lectures on physiology in that university. We had, many years since, formed a similar opinion, when digesting the observations already offered on fevers, which attributes the phenomena of these to a change in the equilibrium of the circulation. We mention this circumstance neither to detract from these authors' credit, nor to add to our own; but, as some confirmation of the claim, we may suggest the consistency of this doctrine, with the view we have given of fever in general.

In our explanation of fever, we attempted to prove that debility was the first change which took place; and, in all the varieties and changes of appearances, debility, we remarked, was always the leading feature. With a view to inflammation, we observed, that, while there was a quiescence of the capillaries, probably a spasm, since debility is its general and principal cause, the action of the sanguiferous system was excited, but that the excitement was partial. If, then, from any cause, this action is excited in a peculiar degree, and if any debility in a given part concurs, inflammation will be the consequence. These are not hypothetical positions. Inflammations chiefly occur in the young, the robust, and sanguine, whose habit, or diathesis, is inflammatory, and from hence called *phlogistic*, a term derived, like

inflammation, from fire, before phlogiston had an existence in chemistry. The phlogistic diathesis consists in a strong action of the arterial system, and increased tone and vigour of the active powers of the circulation, which are evident from the strong, hard pulse, and the general firmness of the whole habit. If any of fever happens, it will be evident that the action of the arterial system will be, in such constitutions, inordinate. The partial debility is also equally conspicuous. No more certain cause of rheumatism exists than topical cold, after the part has been unusually heated; of peripneumony, than previously having breathed warm air; and of any inflammation, than from the same part having been formerly affected with the same disease. All these circumstances point out previous topical debility, quiescence which admits of accumulation, in which inflammation seems to consist.

This forms, however, the extreme case: various are the intermediate ones, in which, though the balance is disturbed, the *vis a tergo* is more or less violent in proportion to the debility, or the debility more or less considerable in proportion to the former force. When in a healthy state a part is rubbed or irritated, a redness comes on, which on the cessation of the cause again recedes. This can scarcely be called inflammation, for it is not a disease. In fact, the balance of the circulation is not disturbed; but if the motion of the fluids is interrupted, and their return by the veins impeded, the usual consequences of obstruction follow; the *vis a tergo* is increased, the vessels distended and weakened. If, on the contrary, a part is weakened, as by cold, the fluids accumulate without any increase of the *vis a tergo*, become red and livid, but by the gradual approach of warmth again recover their usual appearance. This again is not disease; but if the cold is farther continued, so that the power of the arteries behind cannot propel the fluids, chilblains and gangrene ensue.

The great subject of debate has been, whether obstruction really exists in inflammation. Dr. Wilson, from microscopical observations, is convinced that this is the case. We have said that the conclusion is too general. It seems to fulfil all the idea of inflammation, if, from a disturbed balance in the circulation, the blood is accumulated in a part faster than it is conveyed away by the veins or exhalants. Obstruction is not necessary to explain the phenomena; and in some instances, as we have said, the veins swell, and the discharge from the neighbouring exhalants is increased. Yet we are willing to admit, that in every violent inflammation obstruction does take place; but it is unnecessary to distinguish the circumstances with accuracy, as the explanation of the symptoms or the cure will not be affected by the decision.

The view of inflammation thus given will sufficiently explain almost all the varieties, and give a consistency to the method of cure. The only kind, whose pathology is less obviously derived from the foregoing remark, is erysipelalous inflammation. The only difficulty however arises from the inaccuracy of language. We are accustomed to call those internal inflammations erysipelalous, in which the action of the arteries, so far from being increased, is weakened, and which hastens to gangrene rather than suppuration. There is not, however, the slightest evidence that the state of inflammation internally resembles the external appearance

usually denominated an erysipelalous eruption, for this is properly an exanthematous disease, except when in the fauces, where a similar appearance attends the gangrenous throat; but in this case the eruption is a symptom only, and the inactive inflammation hastening to gangrene, the real disease. All the additional explanation will appear from the *ratio symptomatum*, to which we proceed.

The leading symptom of inflammation is *redness*, which has been usually explained from the entrance of the red globules into vessels not adapted to their diameters. This error loci we believe really takes place; but, independent of this cause, the redness proceeds in part from slight extravasations in consequence of rupture, but chiefly depends on the greater quantity of the red globules from dilatation and accumulation. It appeared from the microscopical observations of Dr. Wilson, that slight irritation, instead of producing redness, occasioned paleness, in consequence of the more rapid circulation, and that the redness did not appear until the appearances of the blood's motion had ceased. It must be remarked, however, that these experiments are, in part, fallacious. The circulation cannot be observed but in transparent organs; and when vessels are distended so as to admit of considerable accumulation of blood, they are no longer transparent.

Increased heat is another symptom equally characteristic of inflammation, and this was easily explained by the pathologist from the increased circulation, and consequently increased friction. We know, however, that the change in the blood's capacity for heat, which takes place during the circulation, is equally going on during its stagnation, and when a larger quantity is accumulated in a part, the heat given out in consequence of this change must be necessarily greater. On the approach of gangrene the parts are cold; but this change never takes place till the blood has already assumed a livid hue, and of course has yielded all the heat which could be separated in consequence of this change of capacity.

The *pain* is more easily explained from the distention, and the spasm which also must take place in consequence of the distention. It will be obvious also, that where the vessels are closely confined in membranes, they admit of distention with difficulty, and the pain is proportionally increased. The pain is also in proportion to the sensibility of the organ and the diathesis phlogistica, where the disease in a great degree arises from the violent action of the *vis a tergo*. On both these accounts, the inflammation of the eye is attended with the most excruciating pain. Ligaments and tendons when inflamed are also acutely sensible, though their sensibility is inconsiderable in the sound state. The source of the only other symptom, *the swelling*, is sufficiently obvious.

The *remote causes of inflammation* are either general or topical. The general causes are those of fever, determined in their seat by some accidental cause, generally some debility of the part. Inflammations of this kind are usually inflammatory, arising from excess of action in the larger arteries; but in different states of the atmosphere, or rather in different epidemic constitutions, either a less degree of phlogistic diathesis will produce the accumulation, or the balance is destroyed by the loss of tone in the affected part; often not-

without suspicion of a morbid poison determined to the part, particularly in the putrid sore throat, which seems rather an exanthema than a phlegmasia.

Of the topical causes but a few only are direct stimuli. A thorn in the flesh is one of the most familiar instances of this kind; chemical acrids produce the same effects; but a more frequent cause in the human body is any extraneous body, or any portion of the body deprived of life which acts as such. These continued irritations seem to produce those inflammations, in which, as we have said, there is no decisive evidence of obstruction.

The other topical causes are those of indirect debility, as burning, overstretching, concussions, &c. which we have already shown, with a view to this subject, act by producing atony. The coup de soleil, at least in this country, appears to have a similar effect. See ICRUS SOLARIS.

The terminations of inflammation are said to be by resolution, by abscess, by gangrene, and scirrhus; but this offers a very fallacious view of the subject. In fact, the salutary terminations of inflammation are by effusion and abscess; the fatal ones most commonly by hæmorrhage and gangrene. Scirrhus is usually a previous disease, and excited to cancer by inflammation.

When an inflammation either by the operations of nature or the influence of remedies yields, an action is first perceived in the vessel, the dark colour assumes a brighter hue, the tumour lessens, and an effusion takes place from the adjoining exhalants. The effusion sometimes proceeds and relieves the over distended vessel, but there is scarcely an instance of resolution of inflammation, without some effusion, which occasions the adhesion of contiguous membranes. It consists of the serum of the blood, with its proportion of fibrin. This is commonly the termination of the febrile inflammations. In those which depend on the loss of tone, the effusion is of a different kind; and in these, though it relieves the original disease, yet it leaves one scarcely less dangerous. We allude to the effusion of a watery fluid which sometimes follows inflammation of the lungs, producing hydrothorax. When œdematous swellings follow gout or rheumatism, the danger is less.

When nature or art fails in relieving the inflammation by effusion, the texture of the part is destroyed by the continued pressure of the accumulated fluids, and the whole is melted down into one uniform, opaque, white, mild fluid, called pus; and an abscess is said to be formed. The appearance of an abscess is prognosticated by the cessation of the pain and the distention. But to these symptoms, which occur also on effusion taking place, must be added a throbbing pain, synchronous with the dilatation of the arteries, and irregular shiverings. After a short time a weight is felt in the part, the pain disappears, and, if on the surface, the tumour is soft, and an evident fluctuation is perceived by the touch. The skin gradually becomes thinner, and a little conical apex appears, generally about the centre of the tumour, which is called its pointing; though frequently the skin only becomes thinner, and the tumour softer in one particular part, above, below, or on either side, indiscriminately, and seemingly from accident.

The nature of purulent matter, as well as its source, has been disputed. We have called it a mild fluid, and undoubtedly to all the senses it is so; yet it seems to

dissolve the cellular substance around, and to form for itself a cavity greater in proportion to the resistance it finds in its way to the surface, where it generally tends. When not the salutary termination of inflammation, it is sometimes highly acrid, as in venereal or scorbutic sores; but its reputed acrimony in other cases arises often from its pressure, which destroys the life of the part, and subjects it to the action of the absorbent vessels. An aneurism, in which there is not the slightest suspicion of acrimony, will do the same.

The source of the purulent matter is said to be the serum of the blood, changed to this form by the process of fermentation. This was the opinion of Gaber and Pringle; but De Haen and some modern authors contend, that it is a morbid secretion from the exhalant arteries. On this subject we find it difficult to form an opinion. Were we to offer any, we should say that it consists of the substance of the vessels and of the cellular membrane dissolved in the serum; but this is an opinion we are not prepared to defend. It is certainly an albuminous fluid, which has, however, a tendency to the putrid fermentation. To produce this fluid a certain degree of excitement of the vessels is requisite. When too considerable, it is sometimes bloody; when the excitement is in too small a degree, it is thin, acrid, and glairy; when in a still less, ichorous. In the latter cases we must apply stimulants and astringents respectively, for only when the pus is of a proper nature and consistence, in the language of surgeons laudable, does it contribute to healing the wound.

There is another fluid which certainly is not laudable, viz. that which is found in scrofulous glands, and which is discharged in consumptive cases. This is of a ragged cheesy kind, surrounded generally with streaks of proper pus, apparently from the inflammation of the coats of the containing cyst. It seems to consist of the gluten of the blood so hardened and condensed that it will not admit of solution. The distinction between pus and mucus is not easy to the inexperienced practitioner. In general, mucus is in rounded masses; pus flows more readily: the latter is softer and whiter, with little globules swimming through it, and, when mixed with a saturated solution of potash, a transparent tenacious jelly is separated, while the same solution produces no such change in mucus.

The fatal terminations are hæmorrhage and gangrene. We might have mentioned hæmorrhage among the salutary terminations, but they rarely prove so in this climate; yet occasionally a slight bleeding from the neighbouring glands, as a bloody tinge of the sputum in pneumonia, we have thought useful. In general, however, the salutary hæmorrhages are copious ones, generally from a neighbouring organ, as from the nose in phrenitis; but these are uncommon in this climate. The fatal hæmorrhages occur in the lungs, in the bowels, and bladder, but are not very common terminations.

Gangrene is a fatal termination in the very active inflammations, where the fever runs with peculiar rapidity; or in the very low ones, where want of tone readily admits of considerable dilatation, and consequently compression. In gangrenes the life of the part is destroyed, the redness assumes a livid hue, vesications appear on the surface, and the inflammation is external; pain is no longer felt, a peculiar serenity comes on, with a sinking of the features, which gives a ghastly

appearance to the countenance, and the patient dies with every feeling and every expectation of recovery. When a putrid acrimony occurs in the fluids, gangrene is more to be dreaded in inflammations of every kind: it is particularly common in those diseases which occur in jails and crowded hospitals. There is a kind of gangrene which follows considerable irritation and violent pain, independent of great inflammation. In this case the violence of the excitement seems at once to destroy the tone of the part, and it is in this kind that Mr. Pott has found opium so eminently useful. Some authors have supposed gangrene to be occasionally owing to blood effused; but we have no evidence that blood, if preserved from the access of air, is peculiarly disposed to putrefaction. See ERYSIPELAS, ABSCESSUS, and MORTIFICATIO.

It may appear that, in this disquisition, we have omitted the inflammations of the mucous membranes. These, however, make no part of the present subject; for they arise very generally from a morbid poison, carried to the glands, and the inflammation excited in these organs is attended with an increased or a vitiated discharge. If it were necessary to reduce them to this head, they would be found to resemble the inflammations excited by mechanical or chemical acids without obstruction.

The prognostics in inflammations are more or less favourable in proportion to the importance of the part affected, the constitution of the patient, the violence of the symptoms, and the coincidence of other diseases. Inflammations of the glands, of the ligaments, and the tendons, are tedious in their progress, and the two last leave a disposition for the future attack of a similar disease.

The CURE OF INFLAMMATION will, we think, be greatly elucidated by the former enquiries; and, for this purpose, inflammations must be divided into those attended with a phlogistic diathesis, and those in which distention and dilatation arise in a greater degree from atony than an increased vis a tergo. This distinction cannot be made with accuracy, for the two kinds pass into each other by almost undistinguishable shades. Yet the difference is real, and it will be only necessary to modify the treatment of each when it approaches the confines of the other.

The chief remedy of the active inflammations is *bleeding*, and blood must be often taken in large quantities from a large orifice, since the relaxation which it produces is in proportion to the quantity lost in a given time. If we peruse the writings of physicians in the early part of the last century, we shall perceive that they bled freely and repeatedly where we find a single evacuation only admissible. Constitutions are greatly changed in this respect; luxury has enervated our habits, and the changes in diet have greatly lessened that active constitutional power which forms the essence of the inflammations now before us. In the robust labourer, in a cold season, where the disease has arisen from cold to which the body when heated has been exposed, a large bleeding may be repeated; but in a crowded city, with a person whose constitution has been enervated by a sedentary occupation, or by luxury, whatever the appearances may be, bleeding must be cautiously employed. After a general bleeding, modern refinement, adapting the remedy to the change of

constitution, has employed topical bleedings either by means of leeches or cupping glasses, which relieve the distended vessels, without too far debilitating the system. The inflammations to which copious and active bleeding are chiefly adapted seem to be phrenitis, carditis, pneumonia, rheumatism, and perhaps the psoas inflammation, when it is certainly known to exist.

Emetics we have seen producing relaxation through the whole system; and though they may appear to be contraindicated, when we recollect that a partial debility favours the inflammatory distention, yet any inconvenience which this may occasion is compensated by the freedom which they restore to the circulation in general. In conformation of this idea, we find, that, in the other class of inflammations, where the circulation is more languid, they are injurious; and if given in the ulcerated throat, it is rather with a view of emulging the glands of that part, an effect which renders them so useful in pneumonia, than of counteracting an inflammatory state. The nauseating doses of antimonials are peculiarly useful in such active inflammations; nor in diseases of short duration, in constitutions peculiarly strong, have we any thing to apprehend from their debilitating effects. In all inflammations of this kind, it must be remembered that the increased inordinate action of the arterial system is the chief disease.

Cathartics are not generally indicated in these complaints; yet, as they draw the fluids powerfully from the head, and from the chylopoietic viscera, they are useful in inflammations of these parts, as they act without increasing the phlogistic diathesis in general. They are most advantageous in the earlier stages; nor need we wait till the increased action of the arterial system is taken off by bleeding. As cathartics are peculiarly useful in phrenitis and enteritis, so are they injurious in pneumonia. As evacuations they are perhaps singularly advantageous in rheumatism; though the inconvenience of moving renders them less eligible to the patient than other remedies.

Diaphoretics are apparently well adapted to active inflammation, from the effects which we have already had occasion to explain. In general, however, their stimulant power renders them less advantageous in those cases where the vis a tergo is very actively increased. To this there is only one exception, viz. where the evacuation is from the neighbourhood of the organs affected, as in rheumatism; for it compensates for any disadvantage that would otherwise arise from the increase of the circulation. In general, however, the relaxing diaphoretics, as the nauseating doses of emetics, and the combinations of opium, with either the ipecacuanha in Dover's, the white hellebore in Ward's powder, or with the warmer preparations of guaiacum, are most effectual.

Opium, which we have styled the most certain and powerful diaphoretic, is not always admissible, it is said, from its stimulus, but this is generally inconsiderable, and sometimes unobserved. The chief disadvantage of opium arises from its checking the secretions, so essentially necessary in many of the active inflammations, particularly in pneumonia, hepatitis, and enteritis. When this inconvenience is obviated, as we shall find in speaking of each disease, opium is a useful remedy, and it is occasionally employed, in each, with advantage.

Blisters are of the highest importance in inflamma-

tions of every kind; but when the inflammatory diathesis is considerable, they fail of relieving; and it will be obvious, that, while the disease continues in consequence of the force of the arterial system, the advantages derived from topical depletion cannot be considerable. In the most active inflammations we have sometimes found it necessary to bleed previous to each application of a blister, particularly in rheumatisms, where blisters must be often repeated.

Sedatives of every kind are essentially necessary. A class of medicines, which we have styled *inirritants*, which we shall soon notice, and which consists of those diluents and demulcents which sooth and sheath the irritations of the nervous system, or inflamed membranes, are highly useful in these active inflammations. The other sedatives employed with advantage in such cases are nitre and camphor. The utility of the former is generally acknowledged, except in inflammations of the bladder, where large doses are supposed to produce some additional irritation. The latter is not so generally employed, as it is thought to prove occasionally stimulant, and by some practitioners to be useless. In small doses, however, we have repeatedly found it an advantageous medicine, particularly in those cases where nitre seems to produce too great an irritation. Some of the narcotics promise to be useful in such cases, particularly the hemlock, and the digitalis; but they have not been often employed and of their advantages we cannot speak from experience.

Cold, as a privation of heat, has been considered as an active remedy of inflammation, and employed very freely of late, in one species, the gout. (See *ARTHRITIS*.) In general, however, it is a doubtful and uncertain remedy. When temporarily employed, it is followed by increased action, and will of course exasperate the disease; when continued it occasions torpor, and may produce or hasten gangrene. In external phlegmons it is of use in the early periods, and will sometimes contribute to their resolution; but in internal phlegmasiæ it is generally a dangerous remedy.

It may be questioned, however, whether, when we avoid cold, we should freely indulge a higher temperature. The reason for employing heat has been to promote perspiration, and consequently to relieve internal accumulations; but we have found reason to doubt whether the discharge from the skin, brought on by high temperatures, is truly salutary. In general it appears otherwise; and the warm diaphoretics, of which warm air and warm fluids are the principal, appear to injure more by increasing the circulation, than they relieve by the discharge they produce from the surface. When then we would avoid cold, we would not indulge heat. The temperature of the room should be moderate, and scarcely exceed 62°; the drinks tepid, somewhat about the heat of new milk, a degree peculiarly soothing to the irritated nerves. See *INIRRITANTIA*.

As cold applications are admitted in phlegmons, it may be considered that they would be equally beneficial where the cold air is applied to the part, as in pneumonia and sore throat. In the latter, cold applications are sometimes useful; and nitre or sal prunellæ held in the mouth has been said to relieve the inflammatory angina. The lungs are, however, more irritable; and though great heat is injurious, extreme cold is equally

so; nor can we sink the temperature of the room or of the drinks far below the degrees stated, though perhaps they may be somewhat diminished with advantage. Of this, however, the feelings of the patient are the proper criteria.

Phrenitis and pneumonia are perhaps the only inflammations which form an exception to the general rule, respecting the utility of a *recumbent posture*. In the former the erect position is highly advantageous, and it has been supposed equally useful in the latter; but the subject will be resumed when we speak separately of each.

Inflammations, as the habit is less inflammatory, and the circulation less actively excited, require these remedies in a less degree and diminished power. When we approach that low state in which inflammation proceeds from atony, with a very slight, if any, increased circulation, we must be cautious in all the evacuations. Great inconvenience has arisen from a want of caution in professors and lecturers, who generally remark, in every inflammation, that, should the patient be young and plethoric, some blood may be taken. Many epidemic pneumonias and cynanches occur in which this evacuation would be fatal in forty-eight hours. In the Breslaw epidemic, though attended with topical inflammation from atony, so debilitating was the cause as at once to take off rheumatic pains. The practitioner must consequently attend with care to the reigning epidemic; to the state of the pulse; to the countenance, and all the circumstances which indicate debility; and he must be particularly cautious not to mistake a pulse throbbing from irritation for a hard inflammatory one. The countenance often furnishes a very certain index: if the features are sunk, the eyes staring, the expression lost, whatever are the other symptoms, bleeding must be avoided. The warmer diaphoretics must be preferred also to the nauseating or relaxing ones; and cathartics, particularly the purgatives, carefully avoided. In the more asthenic inflammations of this kind, we must soon have recourse to bark, and the warmest cordials; nor will blisters, as we have had occasion to remark, be always safe. Many modifications of these directions will occur under the separate diseases.

External inflammation is more within the reach of the sight and touch; and to this the former directions are only applicable, when attended with general fever. If not in the vicinity of any large vessel, or in a situation peculiarly inconvenient, we are seldom anxious about its resolution, but suffer it to proceed to suppuration. If it arises from wounds or bruises, the remedies styled *discutient* are useful: these are warm and astringent applications, capable of exciting the torpid action of the vessels, and restoring the tone destroyed by the blow. If these do not succeed, and the accumulation is followed by increased action from behind, the vessels are depleted by topical bleeding, and our discutients applied with increased power, or more frequently repeated. In all such cases, practice gives the firmest support to theory, for emollients are constantly forbidden where resolution is attempted. The use of the preparations of lead rests on some uncertainty. This metal is an apparent exception to the general tonic powers of metallic substances: it seems to render the nerves torpid, and the muscular fibres less

irritable. It is not, therefore, always proper in inflammations where the action of the vessels is inconsiderable; but, in watery solutions, a valuable remedy where the circulation is pushed on with increased energy. When we aim at producing suppuration, gentle and continued warmth, sometimes with a slight stimulus, favours the dilatation of the arteries, and lessens the resistance of the skin. (See FURUNCULUS.) In indolent tumours, the stimulant applications are most useful; in highly inflammatory states, the emollients, with anodynes.

Dr. Cullen has inserted, among the species of phlogosis (external inflammation), erysipelas; but apparently without due consideration, as its nature and symptoms differ essentially from phlogosis. When attended with fever, it is an exanthema; and, when without it, a cutaneous disease.

When inflammation attacks the glands independent of fever, the lymphatic glands chiefly suffer, and the treatment of these is not very different from that of phlogosis. In general, resolution is attempted by topical evacuations, by sedatives, or occasionally by those remedies which excite the action of the minuter vessels. We shall, however, enlarge on this subject, under the diseases where they chiefly occur, viz. SYPHILIS and SCROFULA, q. v.

It might be expected that we should distinguish the inflammations, attended to the active energy of the whole arterial system, from those which are rather owing to atony; but in general these form varieties only, as the putrid peripneumonia, the ulcered throat, &c. Were we to make any approach to such distinction, we should arrange them in the following order, from the system of Dr. Cullen:

- I. *Inflammations peculiarly active.*
 - Phrenitis.
 - Ophthalmia epidemica (Egyptian Ophthalmia).
 - Cynanche.
 - Trachealis and Pharyngea.
 - Pneumonia.
 - Rheumatismus.
- II. *Inflammations less active.*
 - Phlogosis.
 - Ophthalmia.
 - Membranarum and Tarsi.
 - Cynanche.
 - Trachealis.
 - Carditis.
 - Peritonitis.
 - Gastritis.
 - Phlegmonodea.
 - Enteritis.
 - Hepatitis.
 - Splenitis.
 - Nephritis.
 - Cystitis.
 - Hysteritis.
 - Odontalgia.
 - Podagra.
- III. *Atonic Inflammations.*
 - Anthrax.
 - Cynanche.
 - Maligna.

Pneumonia.

Putrida.

Gastritis and Enteritis.

Erysipelatosa.

Arthropoosis.

Podagra.

Aberrans.

Bell on Ulcers, edit. 3, p. 17—36, 47—53; Cullen's First Lines, edit. 4, vol. i. p. 211; Kirkland's Medical Surgery, vol. i. p. 235; Pearson's Principles of Surgery, vol. i.; White's Surgery, vol. i.; Wilson on Febrile Diseases.

1. INFLAMMATION IN A JOINT. See RHEUMATISMUS and HYDRARTHUS.

2. INFLAMMATION OF THE HEART, *carditis*. Dr. Cullen has placed the *inflammatio pulmonis Lomii*, and *pericarditis*, as synonyms, under this genus, included in the class *pyrexia*, and order *febres*, defining it to be fever, with pain in the region of the heart, anxiety, difficulty of breathing, cough, unequal pulse, palpitation, and fainting: in this case also the pulse is small, irregular, and intermittent; the patient frequently faints, and if not speedily relieved the disorder soon becomes fatal. The method of cure is not peculiar, but resembles that of other internal inflammations of the chest. Though the pulse is soft, bleeding, it is said, must be carried to a greater extent than in pneumonia or pleuritis; but in other respects the cure does not greatly differ from that of pneumonia. Where we have suspected carditis we have thought the camphor peculiarly useful. It often seems to succeed pneumonia, or rather the inflammation appears to be communicated from the lungs to the heart or pericardium. See Senac sur le Cœur; Lieutaud's Historia Anatomica Medica; and INFLAMMATIO PERICARDII, No. 15.

3. INFLAMMATION OF THE FAUCES. See ANGINA.

4. INFLAMMATION OF THE THIGH. Inflammation sometimes takes place under fascia lata femoris, followed by very unkindly suppurations. The usual remedies of active inflammation must be employed; but whenever matter is formed it should be discharged as soon as it is discovered.

The remedies of active inflammation do not always appear to be indicated by the violence of pain, or degree of fever, and the disease sometimes approaches in the insidious form of the psoas inflammation. It is distinguished, however, from the latter, by want of pain on bending the body. The diagnosis is, indeed, of less importance; as free bleeding and a sudorific regimen, with the relaxing diaphoretics, are useful in both. The inflammation of the thigh terminates more safely than that of the psoas muscle, though, as the matter falls down, the abscess does not soon appear, and then points at a very distant part. The sinus is, therefore, generally extensive, and requires a steady, though not a violent, pressure.

5. INFLAMMATION OF THE LIVER. See HEPATITIS.

6. INFLAMMATION OF THE INTESTINES; *enteritis*. Dr. Cullen places this disease in the class *pyrexia*, and order *phlegmasia*; defining it a typhus, attended with pungent, tensive, pain of the abdomen, chiefly felt round the umbilicus; a vomiting and obstinate constipation. He distinguishes two species.

1. ENTERITIS PHLEGMONODEA, inflammation of the bowels, with acute pain, strong febrile affection, vomiting, and costiveness.

2. ENTERITIS ERYSIPELATA, inflammation of the bowels, with pain and fever, more mild than the former, without vomiting, but with an attendant diarrhœa.

The disease consists in an inflammation of the external coat of the intestines, and differs greatly from an inflammation of the villous coat, or mucous membrane, usually attended with aphthæ or a dysentery. (See DYSENTERIA.) According to the different parts of the intestine in which the inflammation is seated, different names have been assigned; but the treatment is the same in all.

If a sharp pain, with a fever and nausea, is felt above the navel, and below the stomach, the colon under the stomach is the probable seat of the inflammation: if in the right hypochondrium, under the spurious ribs, then that part of the colon which joins the ilium may be affected: if in the middle of the belly about the navel, the small intestines. The different parts affected need not, however, be accurately discriminated, since, as we have observed, the method of cure is the same.

The causes are either those of fever in general, obstructions of any kind in the intestines, intususceptio, or wounds. The usual causes, however, are those of fever.

The symptoms are, a shivering, with an uneasiness in the bowels soon increasing to a violent pain, occasionally, at first, remitting, but soon becoming continual. Generally the whole abdomen is affected at the same time with spasmodic pains, which extend to the loins, apparently owing to flatulency. The pulse is small, frequent, generally soft, but sometimes hard, and at last irregular and intermittent. The extremities are cold; the strength sinks rapidly. Costiveness, which has sometimes preceded, becomes unconquerable, or slight mucous discharges are brought off with great straining. After a short time the flatulency increases to vomiting, and every thing is rejected. The tongue is dry, thirst great, the urine often obstructed, or high coloured, and discharged with heat and difficulty. The breathing is quick. The patient bends forwards, because the abdominal muscles are spasmodically contracted; great tension and soreness are felt externally; the vomiting increases to violent and incessant retchings, in which at last the fœces are returned, and after this scene of distress has continued, without relief from stools, the whole commotion ceases; the pain goes off, and the patient appears to be relieved; but his face grows pale, the under eye lid becomes livid; the pulse continues soft, more regular, though small and weak; the extremities are cold; delirium and convulsions come on; and the patient expires, often discharging very fetid stools in the moment of death.

This disorder seldom terminates in an abscess. When this is the case, the pain abates, and is converted rather into a sense of distention, and irregular cold fits, with other symptoms of internal suppuration; the pain, the great frequency of the pulse, and other symptoms, go off. When this abscess bursts, the patient swoons, and seems relieved from a sense of weight in the part where it was, but soon expires in cold sweats.

Inflammation in the external membrane of the intes-

tines is distinguished from the stone in the kidneys or in the ureters, from the pain in the latter cases shooting down the thigh, from spasmodic pains of the belly, from colic, and from other obstructions there in which no inflammation attends, by the external soreness and fever.

The disease, however, with which it is most easily confounded, is the inflammation of the peritonæum, in which there is equal external soreness, and often an equally obstinate constipation. But in the latter the pain is more pungent, the difficulty of raising the body greater, and when stools are procured the relief is inconsiderable. The passage of a gall stone sometimes puts on the appearance of enteritis; but in this case the pulse is seldom affected; the pain is confined to the pit of the stomach, and at last shoots through the body to the back, in a manner that cannot easily be mistaken.

If the pain shifts, the vomiting returns only at intervals, and clysters procure a truly feculent discharge, there is room to hope. If the pain abates suddenly, with chillness and shivering, a suppuration is forming. When every thing is rejected, the patient very weak, the pulse fluttering, the countenance pale, the breath offensive, danger is imminent. Clammy sweats, a small intermitting pulse, fetid or black stools, a total abatement of pain, are signs of mortification, and death soon follows.

In the treatment of enteritis there is much doubt. We are ordered to bleed freely, though the pulse is small, and to repeat it till the pulse rises. When the patient is a laborious countryman, and the disease induced by drinking cold fluids in a heated state, this advice may be useful; but it is not generally so. Perhaps bleeding is more seldom necessary in this disease than in any other inflammation, for it rapidly tends to mortification; and, should it not at once relieve, it soon proves fatal. The salutary termination is by a discharge of fœces. If this can be obtained, the patient is safe; but, unless free, copious, and truly feculent stools are procured, the most promising appearances in every other respect will deceive. These are procured by laxatives; but the operation of laxatives is assisted by clysters, blisters, and the warm bath. Emetics in this case are inadmissible; for vomiting soon comes on, and prevents the action of the only certain remedy. The cathartics, first used, are the milder kind, as castor oil, salts with infusion of senna and manna; but these are seldom sufficiently powerful, and are soon rejected. We must then have recourse to the more acrid purgatives, and the colocynth pill with calomel is substituted. This medicine is often given in considerable doses without effect; and the end is at last obtained by the former medicine, salts and senna.

In this period the operation of cathartics is greatly assisted by the frequent injection of clysters. These, to be effectual should be of the most active kind; and the decoction of colocynth with salts, the infusion of tobacco, and the vinum antimoniale, have been employed in this way, often without apparent advantage; but the frequent solicitations downward seem to assist the operation of medicines given by the mouth.

In this course we are almost constantly interrupted by the vomiting, and it has been usual to add opium to the laxatives, to check that irritability of the stomach

which discharges them. The disadvantage of this plan is, that it delays the cathartic effect of the medicine, till, by the powers of the stomach, its nature is changed. We have, therefore, preferred omitting for a time the laxatives, and giving the opiates freely. If pain is checked and the inflammatory state relieved by a blister, we have found no inconvenience if the stools are delayed for a day or two. It is said, indeed, that the disease is fatal in three days: but this is owing probably to the bleeding: where this is omitted, the disease has continued for six or eight days, and at last terminated favourably.

If then the usual laxatives, assisted by clysters, do not procure motions, and violent vomiting comes on, a grain of opium may be given in a single pill. If this is rejected, a tea spoonful of the tinctura opii camphorata may be taken alone, and repeated every hour till the stomach is quieter. This quantity is lost about the fauces, and its anodyne effect communicated to the stomach. We may, in the mean time, inject clysters; but should give nothing by the mouth, except a very small quantity of toast and water, or a very little peppermint tea. After about eight or ten hours the eolocynth pill with calomel, or the infusion of senna with salts, may be cautiously tried, in small quantities, at short intervals; and stools are often in this way successfully procured.

At any part of this period, if the soreness and tension are considerable, a blister may be applied to the abdomen, or the patient put in the warm bath. Each remedy contributes to relieve the pain; but we have suspected that the warm bath hastens mortification. At least we have not been so successful, where it has been employed, as in those cases in which it has been omitted.

Dashing cold water against the legs and thighs, a remedy sometimes employed in the iliac passion, has been recommended in enteritis; but we suspect that it is not a safe remedy when inflammation has taken place. Bathing the abdomen with warm water, rendered more stimulant by camomile flowers and wormwood, generally precedes the application of blisters. Tartarised antimony, given in doses of a quarter or an eighth of a grain, and repeated every quarter of an hour, sometimes produces motions, when every other remedy has failed.

It often happens, that, in the moment of approaching mortification, a sudden resolution takes place, and stools are evacuated. The extremities have perhaps already begun to grow cold, and languor to come on. In such cases, wine, with warm generous cordials, will prevent the approaching death, if the stools are freely kept up; but, either in this case, or when the relief is obtained at an earlier period, the evacuations from the bowels must be copious, free, and unremitting, while the stools are dark. It is too common to fear the debilitating effects of purging, and, after a few motions, to interpose opiates; but the debility must be indeed great to justify this conduct, for a relapse frequently follows.

See COLICA and ABSCESSUS INTESTINORUM.

The erythematic inflammation of the intestines may be treated as that of the stomach. See INFLAMMATIO VENTRICULI; Cullen's First Lines, vol. i. p. 372, edit. 4.; Edinburgh Medical Commentaries, vol. iii. p. 722.

1. INFLAMMATION OF THE MAMMÆ, *mastodynia*. Dr.

Cullen places this as a variety of the *phlogosis phlegmone*; and though it may happen at any time, it usually attacks those who give suck. A shivering most frequently precedes, and the inflammation with more or less fever; a quick pulse, thirst, head ach, and difficult respiration, follow.

As the usual methods to prevent the afflux of milk in the breast are uncertain, to guard against inflammation, the mother should consent to suckle her child, at least during the first month. After this time, by gradually discontinuing the sucking, keeping the bowels lax, and the breasts as empty as possible, by means of glasses, inflammation may be usually prevented. But if it should actually take place, bleeding, a thin spare diet, laxatives, and applying a sedative or discutient embrocation by means of linen rags, which should be moistened with it as often as they dry, will be generally successful. The lotio ammoniæ muriatæ of Mr. Justamond is prepared in the following manner: ℞. ammoniæ muriatæ ℥ i. sps. rorismarini ℥ i. In pulverem redige ammoniam, et in spiritu solvatur. In the early stage of this disease, the lotio ammoniæ acetatæ is recommended. ℞. aquæ ammoniæ acetatæ, sps. vin. rectif. aq. distillatæ āā ℥ iv. m. Some prefer the aqua ammoniæ acetatæ alone; or, a fomentation made of a decoction of poppy heads, in a pint of which an ounce of crude sal ammoniac is dissolved, will often succeed. To each of the lotions above mentioned the tinctura opii may be occasionally added. If the inflammation does not yield to this management, the best method is to encourage a suppuration without delay. See ABSCESSUS PECTORIS, and MAMMÆ; Bell's Surgery, vol. v. p. 396.

8. INFLAMMATION OF THE MEDIASTINUM, *mediastina*. The cause and cure are the same with those of pleurisy, and the symptoms are often similar. The pain, however, is more confined to the sternum, and shoots across to the back. There is a difficulty of breathing, with cough, but not always, attended with spitting. These symptoms are not so violent as in a pleurisy, nor is the pain on inspiration so much increased, or the inflammatory diathesis so great. Suppuration is with difficulty avoided, and generally fatal.

9. INFLAMMATION IN THE MESENTERY. See PERITONITIS.

In this disease there is a languid slow fever, without thirst or other violent symptom; a loss of appetite, a sense of tension, and weight below the stomach, without much hardness, and only discoverable by pressing on it. This tension is without much pain, because the mesentery hath but a small degree of sensibility. The stools are often chylous, and succeeded by a discharge of thin ichor, without any sense of pain; sometimes pure and unmixed, and sometimes mixed with the feces. These symptoms are mild and gentle, if the mesentery only is inflamed; but if the liver, spleen, or any of the intestines, are also affected, they are more violent, and distinguished by the appropriate symptoms of each disease.

These inflammations generally terminate in abscesses; and the purulent matter is sometimes translated to other parts. The disorder, therefore, is often found to recur, and in this case sometimes the fever returns, or is occasionally changed into a colic. Inflammation of the mesentery is, however, very seldom an idiopathic

disease. It chiefly occurs when the glands are obstructed, and any cause of topical irritation combined.

When the presence of this inflammation can be discovered, the method of cure will be the same as that of an inflamed liver or spleen. Bleeding is, however, scarcely admissible.

INFLAMMATION OF THE MUSCLES OF THE BELLY, *myocolitis* of Vogel.

When these muscles are inflamed, the skin is greatly distended; and if they are swelled, the figure of each is often preserved, and fever generally attends. Pain is considerably augmented in sneezing, straining at stool, breathing, or any exertion, and is often felt at the origin or insertion of the muscles, which distinguishes this inflammation from any internal one.

The rheumatism sometimes attacks these muscles; and they suffer from pressure, when patients from a stone in their bladder seek for relief, by resting their weight upon some hard body in a prostrate position.

This complaint is easily distinguished from a colic, an inflammation in the liver, or any of the subjacent viscera, by the considerable distention, the very early soreness, and the circumstance just mentioned, viz. the pain shooting to the false ribs and the spine of the ileum.

The myocolitis scarcely in any instance terminates in mortification or abscess. It is very commonly of the rheumatic kind, and yields to general and topical remedies, the latter of which may approach very near the seat of the disease. Fomentations are particularly useful; but the disease is rare.

If the hardness is considerable, and a throbbing pain perceived, an abscess is forming, and should be encouraged by emollients, that the discharge may be external. Hecurnius observes, that these muscles are covered with so dense a membrane, that abscesses require the knife; and, if the opening is neglected, they sometimes become scirrhus. Hildanus thinks that these tumours should be opened more early than is usual in other instances, to secure an external discharge; for the matter is apt to pass betwixt the muscles, and form sinuous ulcers, as bandages cannot easily be applied. The cold air is particularly offensive, and the air in the room should be moderately warm, when the abscess is opened, or the wound dressed.

Bleeding, with purging, and such other means as are used in inflammations of the external parts, should be employed, and steadily pursued.

11. INFLAMMATION OF THE EYE. See OPHTHALMIA.

12. INFLAMMATION OF THE ŒSOPHAGUS sometimes attends ANGINA, q. v.; but is occasionally an idiopathic disease. We have mentioned it under the title of *angina pharyngea*, described by Eller de *Cognoscendis, et curandis morbis*, p. 172. It is the *angina sine tumore* of the ancients, and is relieved by cooling subacid drinks. Eller recommends external cataplasms to draw any matter that may be formed outwardly, but no danger of this kind seems to impend. We have seen it occasionally as the effect of swallowing acrimonious fluids, and once from a pill of calomel sticking in the pharynx; but in each case the inflammation was followed by no disagreeable consequences; nor was the disease obstinate.

13. INFLAMMATIO OMENTA'LIS. See PERITONITIS.

14. INFLAMMATION OF THE BONES. The blood vessels from the periosteum to the bones run between their laminæ, whilst others pass through particular perforations to the diploe of the cranium, and the marrow in the bones; from these arise the separation of the corrupted parts, and the restitution of such as are lost. Inflammation may, therefore, be seated in the bones, and is attended with obstinate and violent pains, seeming to the patient to be deep seated. Hence also arises a spina ventosa, &c. See INFLAMMATIO PERIOSTEI, N^o 16.

15. INFLAMMATION OF THE PERICARDIUM, *pericarditis*, which Dr. Cullen considers as synonymous with carditis, or inflammation of the heart; adding, that "the pericardium has been known often to be inflamed, without any other symptoms attendant, except those of a peripneumony." The pain, however, seems to be deeper seated, and is not so much increased upon inspiration. The cure is the same with that of pleurisy or peripneumony.

16. INFLAMMATION OF THE PERIOSTEUM. Besides the other usual causes of inflammation in other parts, the venereal disease and the scurvy induce it in this. The venereal poison is a frequent cause, when the periosteum within the bone is the seat of the disorder.

When the external periosteum is inflamed, a deep seated pain, heat, and sometimes a pulsation are felt; and, when the part is not thickly covered, the pain will be augmented by pressure; muscular motion, however, always increases it. That the membrane which lines the bone internally is the seat of the inflammation appears probable, from the want of pain on pressure, or motion; by the absence of pulsation; by receiving no relief from any position of the pained part; and particularly by a sensation of the bone outwardly, splitting from within.

Inflammations in both membranes of the bone proceed from the same causes, produce the same effects on the part of the bone to which they adhere, and terminate either in an abscess or a gangrene; but when the inner membrane is affected with gangrene, the marrow and bone are both destroyed.

If inflammations of these kinds are not speedily removed, the periosteum will be destroyed; and cannot be renewed until the bone exfoliates, and is restored. In this period the incumbent parts will be irritated by an acrid sanies, and malignant ulcers produced, especially if a large portion of flesh covers the bone, and hinders a decisive incision on the part.

The cure is as that of all other inflammations; but the matter must be directed outwards by fomentations and incisions, if the inflammation cannot be discussed by bleeding, purgatives, &c. For this purpose, after these general remedies, softening fomentations and poultices may be applied; but if these fail, it remains only to cut down through the flesh to the bone, if the part admits. Amputation is often, however, at last necessary.

When an abscess begins to form, it is known and treated as described in the article ABSCESSUS PERIOSTEI.

17. INFLAMMATION OF THE RECTUM is rarely so acute as that of the small intestines, nor so apt to

affect the pulse or the stomach; nor is there such a stricture as to render the intestines impervious. The cure is the same as inflammation in any of the other intestines; purgatives are equally necessary, and ought always to be employed. Clysters, from the soreness, are inadmissible, and sitting over warm water useful.

18. INFLAMMATIO RENUM. See NEPHRITIS.

19. INFLAMMATION OF THE SPLEEN, *splenitis*, and *pleuritis splenica*. Dr. Cullen places it among the *phlegmasiæ*; defining it febrile affection, attended with tension, heat, tumour of the left hypochondrium, and pain increased on pressure, without signs of a nephritis.

Lommius observes, that this disorder is rare; that it is attended with a hard and a throbbing tumour, a pain in the left hypochondrium, a continual violent fever, extreme heat, unquenchable thirst, a blackish tongue, a total loss of appetite, with a difficult, and, as it were, imperfect respiration, like that of children when they sob through anger. Aretæus adds, that the pain attending inflammation in the spleen is not considerable. If the distemper continues, not accompanied by an ulcer, the patients have an aversion to food, are swollen, have a bad habit, a disagreeable aspect, with many round, livid, hollow, foul, and incurable ulcers over the whole body, and die cachectic; but such as have only a small, hard, and scirrhus tumour feel little or no pain, and consequently live longer. A dropsy, a consumption, or a colliquation of the whole body, are its frequent consequences.

The cure is that of other violent internal inflammations; but the India punctures and scarifications are employed by the native practitioners.

20. INFLAMMATIO TESTIUM. See HERNIA HUMORALIS.

21. INFLAMMATIO UTERI, *hysteritis*, and *metritis*. Dr. Cullen defines this disease a febrile affection, attended with heat of the hypogastric region, tension, tumour, and pain; the os uteri painful on being touched, with vomiting.

Women, after child-birth, when the lochia are impeded, are sometimes subject to this complaint: but it does not often occur, except as in idiopathic inflammation; for bruises, external stimuli, obstructed menstrua, or obstructed lochia, in very few instances produce real permanent inflammation. The imprudent use of instruments, or violence in delivery, is not a very uncommon cause. When it occurs from any of the former causes, the symptoms are chiefly those of irritation rather than inflammation. The pain at the bottom of the belly is neither throbbing nor constantly acute; the pulse is, as usual after child birth, frequent, often small, sometimes irregular; in strong habits, and after early abortions, hard. Subsultus tendinum, and the other symptoms of irritation, come on; the womb mortifies, and the patient sinks. In the unimpregnated state the pain is more constant, circumscribed, and throbbing; the pulse hard, full, and strong, with other symptoms of general inflammation; or, if the disease rises to a greater height, the pulse is small and frequent, and suppuration is more frequently the consequence.

In both, as different parts of the womb are affected, there is a strangury, or a suppression of urine, and the urine discharged is fetid and hot; or a tenesmus attends, with a pain in going to stool; there is pain in

moving the lower extremities, or swelling, with heat, to be felt at the os tincæ, which is usually shut. The belly is tense; a soreness is felt on pressure; a red stain sometimes extends up to the navel, and turns black when fatal: if it occurs in an impregnated uterus, an abortion follows.

It often happens that the woman can only lie on her back; and on turning on either side, she feels a painful heavy mass fall to that side; with an excessive pain in the loins, kidneys, and groin, of the opposite side. The pain sometimes extends to the thighs.

This disorder may be removed by a spontaneous eruption of the menses, or of the lochia; or, after an abortion, or child-birth, by the patient's falling into a constant, equable, gentle, long continued sweat. If it terminate in an abscess, or a mortification, both are fatal; but a metastasis may be a means of relief.

Bleeding is useful at the first attack, and if the discharge is then copious, it is found to be salutary; but, if at a later period, it sinks the patient with marks of debility, or hastens gangrene.

In abortions and labours, where the patient is not greatly debilitated, if the pulse is hard, and not very frequent, the loss of blood by the arm is borne with advantage; but it cannot be repeated; and the general method of cure will always depend on mild diaphoretics, as the pulvis antimonialis and haustus salinus, carefully avoiding irritating purgatives. To these may be added anodyne and antispasmodic fomentations.

In delicate or feeble constitutions, after child-birth, and where there is no hardness, but great frequency of the pulse, this disorder too often proves fatal. All that can be done is to keep the patient moderately warm, exciting, if possible, a gentle perspiration by farinaceous decoctions, in small quantities, frequently repeated, and applying fomentations and poultices, supporting the strength by the moderate use of wine, and occasionally the bark. All extraordinary evacuations are dangerous. Even the perspiration must be the gentle diaphnoe formerly described.

Every irritation, as external pressure, urine in the bladder, or from fæces in the rectum, must be avoided. Urine, if necessary, may be drawn off with the catheter, and the bowels may be emptied by repeated clysters, which are useful also as internal fomentations, and these are particularly necessary when the irritation is communicated to the rectum. Blisters are dangerous remedies, as their irritation may be conveyed to the neck of the bladder. Opiates, however, may be freely given, and, indeed, to a considerable extent, if costiveness is avoided by mild laxatives.

If suppuration comes on, we are told to direct it to the perinæum. We may do so, but our success will be inconsiderable. Abscesses in the uterus are rare, but they are very generally fatal. See Fernellius; Fordyce's Elements of the Practice of Physic, part the second; and Hamilton's Outlines.

22. INFLAMMATIO VAGINÆ may occur from any cause which produces inflammation in other parts, and must be cured by the same means; but emollient, saturnine, and anodyne injections are particularly useful. When it happens after delivery, it is occasioned by the head of the child being long retained in the pelvis.

If the swelling and inflammation be not very great,

they are generally removed by the discharge of the lochia; but if the internal membrane of the vagina is inflamed, emollient injections must be thrown up from time to time, and a piece of prepared sponge should be introduced, to prevent the effects of the adhesive inflammation. Soak a piece of sponge, of a proper size, to keep the vagina open, when expanded, in warm water; then bind it tight with a string, cutting off any irregularities or lumps. When dry, take off the string, and the sponge will remain in the same form; anoint it with lard, and introduce it into the vagina, the moisture of which will expand it.

If the pressure was so long continued as to obstruct the circulation, a mortification will ensue, which if partial only, the mortified parts will slough off. This is probably the case, if the woman complains of great pain after delivery, a fetid smell, and a discharge of sharp ichor, or of pus and matter from the vagina. Emollient fomentations may be thrown up in such circumstances; dossils of lint, dipped in any warm balsam, may be applied; and when the sloughs are separated, great care should be taken to prevent the vagina from coalescing, either by introducing dossils of lint or pieces of sponge. Inflammation and sloughing of the vagina occasionally happens from violence of any kind.

23. INFLAMMATIO VENTRICULI, *gastritis, cardialgia inflammatoria*. Dr. Cullen places this, as usual, in the order *phlegmasia*, defining it a typhoidal pyrexia, attended with anxiety; heat and pain in the epigastric region, increased on taking any thing into the stomach; a propensity to vomit, and immediately throwing up what is taken, with a hiccough. He distinguishes two species:—1st, *Phlegmonodea*, when from internal causes, in which the pain is acute, and the febrile affection violent. 2d, *Erythematica*, when from external causes, and the pain with the febrile affection is of a milder nature, with an erysipelatous inflammation appearing in the fauces. He is certain, he adds, from many observations, that of the gastritis, as well as the enteritis, there are two species, of which one is phlegmonous, and the other erysipelatous; and, therefore, he has distinguished them: though he confesses that the symptoms of the erysipelatous inflammation of the stomach, and more so those of a similar affection of the intestines, are often obscure and uncertain; but of these he has spoken, that posterity may investigate the subject more diligently.

It is produced from nearly the same causes as the inflammation of the intestines, except intromission and hardened feces, and it is more liable to be excited by acrid substances. It rarely occurs from external causes, though we have seen three instances in which it has arisen from external cold.

When the stomach is inflamed, there is soreness externally; a pungent, fixed, burning pain, with a distention and tumour, sometimes a pulsation in it: the mildest drinks increase the pain, bring on sickness, vomiting, purging, or hiccough. A continual uneasiness is felt about the præcordia, a difficulty of breathing and swallowing, with a pain in sneezing: the pulse is small, quick, hard, and intermitting; the extremities cold, with clammy sweats and faintings: sometimes a temporary mania, and, in one case, a hydrophobia. When from a wound in the stomach there is frequently little or no pain; but the patient sinks with all the symptoms of irritation.

Inflammation in the stomach must be distinguished from a cardialgia, a circumstance by no means difficult, as neither vomiting nor fever attend; and from an inflammation in the convex part of the liver; which, however seldom occurs without some inflammation of the stomach.

This disorder is seldom so dangerous as is represented. Indeed it seldom occurs in its acutest form; but mild nutritious drinks, in very small quantities, nourishing clysters, with a blister externally, has generally relieved. Bleeding, we are told, must be freely used: it may be so, but we have never found it necessary. All stimulants are undoubtedly injurious. When highly acute, a metastasis takes place to the head, and violent phrenitis supervenes: in other circumstances it quickly terminates in gangrene, a change known by a cessation of pain, a coldness about the præcordia, a languid or an intermitting pulse, with a calm serenity, without hiccough.

The drink should neither be cold nor hot, but gently warmed. Demulcents and emollients are best adapted for the common drink, with small portions of nitre, or of the rob of currants.

A solution of gum arabic, or spermaceti made into draughts, in each of which may be gr. v. of nitre, and about a drachm of the syrupus æmeconia, may be repeated as often as seems necessary for moderating the pain; and checking the vomiting.

If acrid poison, or an excess of eating, is the cause, an active emetic may be given; but on all other occasions avoided. The emetic preferred is sweet oil; but one that acts with effect and quickly is more effectual: of this kind is the vitriolated zinc.

If an abscess bursts, a milk diet, with the mildest food, in small quantities at once, is only necessary.

The erythematic inflammation of the stomach comes on insidiously; but sometimes it is evident by the inflammation appearing in the pharynx, as well as on the whole internal surface of the mouth. When, therefore, an inflammation of this kind affects the mouth and fauces, with a frequent vomiting, and an unusual sensibility in the stomach, we may suspect that the same affection extends downward. Even when no inflammation appears in the fauces, yet if a pain be felt in the stomach, with a want of appetite, anxiety, frequent vomiting, an unusual sensibility to acrids, some thirst, and frequency of pulse, we may suspect the existence of this disease in the stomach. The inflammation often extends farther, occasioning diarrhœa and mucous discharges from the rectum.

The treatment will vary according to the causes, &c. When from an acrid matter taken in by the mouth, it must be evacuated by a quick emetic; by large draughts of warm mild liquids; or by the proper antidote, if the nature of the poison is known. If symptoms of inflammation are manifest, bleeding, blisters, fomentations, and frequent emollient laxative clysters may be used. But as the affection often arises in putrid diseases, all that can be done in such circumstances is to avoid irritation, and to throw into the stomach as much of mild and of acedent aliments as it can bear. When the disease is a little alleviated, a light infusion of bark, with a few drops of any mineral acid, is borne with ease, and is highly beneficial. See Cullen's First Lines, vol. i. p. 356, &c. ed. 4.

24. INFLAMMATIO VESICÆ, *cystitis*, and *cystiphlogia*. This disease is also placed by Dr. Cullen in the order *phlegmasia*; and defined a febrile affection, attended with pain and tumour of the hypogastric region; frequent and painful micturition, or ischury and tenesmus. He distinguishes two species. 1. Cystitis from internal; and, 2. from external causes.

It is produced by the usual causes of internal inflammation, or from topical irritation; as acrid diuretics, or a calculus.

A pressing and burning pain, with external soreness, is perceived in the region of the bladder above the pubes, and in the perinæum, soon after a febrile attack. If the neck of the bladder be inflamed, the urine is retained, with frequent stimulus to its evacuation;—if the fundus, there is a continual discharge, with great efforts to throw out a larger quantity, which the patient conceives to be contained in a bladder. Frequent attempts to expel the fæces, with which the rectum appears to the patient to be always loaded, increase the pain very much, particularly when any hard fæces are contained in it. The pulse is frequent, but seldom hard; the extremities cold, with restlessness, sickness, vomiting; sometimes delirium, and other symptoms of irritation.

This disorder, if very violent, usually terminates soon, either in a recovery or death; frequently the latter, generally from a gangrene. So violent an inflammation of the bladder seldom, however, occurs. We have often seen it without considerable danger, chiefly from topical irritation, and once only from catching cold.

This disorder is sometimes relieved by an increased secretion of mucus from the internal membrane, resembling, in appearance, pus, but much lighter, and more uniform; or by a metastasis. When suppuration follows, pus is discharged with the urine, passes externally through the perinæum, or into the cavity of the abdomen, where it proves fatal. The ulcer in the bladder and perinæum are difficult of cure.

Inflammation in the external coat of the bladder should be distinguished from that of the internal; and inflammation in any part of the bladder should be distinguished from inflammation in the adjacent parts, as well as from that retention of urine which proceeds from other causes. The distinction is, however, by no means difficult, as, when the external membrane is affected, the pulse is hard, and the external soreness considerable; nor is the great irritation to make water so painful or frequent.

In the cure, bleeding is seldom necessary to any considerable extent; but the bowels should be kept freely open by such laxatives as do not irritate the rectum.

Relaxing medicines, such as the pulvis antimonialis and haustus salinus, should be given early, and repeated frequently. Fomentations to the pubes and perinæum are highly useful; and mild clysters, which act as such, should be frequently injected.

If the urine is retained, decoctions of mucilaginous herbs may be taken; but we should always reflect, that, though we abate the acrimony of the urine in this way, we increase the disease. Such decoctions should not be drunk in too large quantities, and gum arabic kept in the mouth will sheath the inflamed parts without adding to the quantity of urine. If necessary, the catheter must be introduced; though much care is required in the attempt, which often fails.

If, notwithstanding due evacuations, spasmodic contraction with much pain continues, opiates in considerable doses, such as tinct. opii. gr. xx. every three or four hours may be given, taking care that no accumulations take place in the bowels.

The patient may be placed in the warm bath two or three times in the day. Blisters are sometimes applied to the perinæum, and with advantage; the plaster should, however, be covered with thin gauze, and removed as soon as a vesication has taken place. In this way we have often applied them with success. The rubefacients promise greater utility with less inconvenience, but we know not that they have been tried.

If by irregular shivers, and the diminution of pain, a suppuration is suspected, we must wait its progress, and the disease will then become an ulcer of the urinary passages, which must be treated accordingly.

25. INFLAMMATO'RIA FE'BRIS. Dr. Cullen places it in the class *pyrexia*, and order *febres*; and as a synonym of synocha; defining it heat, greatly increased; a frequent, strong, and hard pulse; high coloured urine; and the functions of the sensorium somewhat disturbed. This fever is the *continua non putris* of Boerhaave; and the *febris acuta sanguinea* of Hoffman.

When fever is attended with an inflammatory diathesis, or when actual inflammation affects any part during the existence of fever, the patient is said to labour under one of an inflammatory kind; but, according to the different parts in which the inflammation is seated, different denominations are given to the disorder, as we have seen in the preceding articles.

In strong constitutions it is produced by any of the causes of fever; but it has been doubted whether inflammatory fever exists, independent of topical inflammation. There is little doubt but that it is most commonly attendant on topical inflammation, though it certainly exists alone. When we consider the distinctions of fever, we shall find that they have been too curiously subdivided; and that fever is a more simple disorder than pathologists have represented it. At present we shall only remark, that this disease is distinguished by a hard pulse and more considerable heat than usual, generally owing to the strength and tone of the habits it attacks.

The horror and rigor of the attack are violent, but short in their duration, and are followed by a violent hot fit, in which all the symptoms indicating increased action of the arterial system are very conspicuous. The fever is often terminated by topical inflammation, or a hæmorrhage, and is alone fatal, though it may become rapidly so, when the inflammation falls on the brain, lungs, or intestines. If none of these consequences happen in the second week, the strength diminishes, and the fever goes off with a perfect crisis, or changes to a typhus. When attended with local inflammation, and this is removed, the same change sometimes takes place, and the typhus is rendered more dangerous, by the weakness induced from the necessary evacuations. This has been the reason of nosologists introducing the genus *synochus*; but *synochus*, the real disease, is very generally a typhus, and the previous inflammatory symptoms are accidental only. The cause of symptoms so dissimilar is not easily assigned. In some cases the infectious miasmata are only excited to action by the

previous inflammatory fever, and in others the irregular action subsequent to the spasm is directed to a particular organ, and the irritation excited by its inflammation increases the force of the circulation, so as to produce the symptoms described. See FEBRIS and INFLAMMATIO.

The causes of inflammatory fever are chiefly cold when the body is heated; but it may also arise from accumulations in the stomach, or topical irritations. The stomach and bowels are the chief sources of this disease in children; and, indeed, the most common causes, when it appears independent of topical affections. The other sources of irritation are obscure.

Bleeding, the common remedy with indiscriminating practitioners, must be employed with caution. If an inflammatory fever attacks a young, strong, robust labourer, it may be employed with freedom; but we should always recollect that though pneumonia, phrenitis, or any active inflammation, may come on, a typhus may be also at the bottom. The pulse may direct; but, as we have often observed, it requires peculiar judgment to distinguish between a strong and an irritated pulse, as well as between an apparently low and a labouring one. We have found the countenance a good criterion; and if the features are sunk, with any apparent anxiety in the countenance, whatever are the other symptoms, bleeding must be avoided. On the contrary, strong rigor, soon succeeded by violent heat, flushed face, a sparkling and a full eye, will require a free and active evacuation from the arm, which may be repeated according to circumstances.

Emetics are remedies of the utmost importance, and in children, where a foulness of the stomach is the principal cause, they will often carry off the fever. In general, the headach and fulness of the vessels appear to contraindicate this remedy; but we have already observed, that the increased fulness is temporary, the advantages permanent. Yet where the determination to the head is very violent, and the vessels have not been depleted by venesection, emetics should be avoided.

Cathartics are still more necessary than emetics, and less dangerous. They not only relieve the head, but they prevent determinations to the lungs and liver, and lessen the violence of typhus, should its fomes be latent. The saline purgatives, with senna, are, in this case, preferable.

The cooling sedatives and irritants must be freely employed. The antimonials, nitre, with all the other neutrals, are valuable remedies; and, where the head is affected, camphor, united to vinegar, has been employed with advantage. (See PHRENITIS.) Opiates are often necessary when violent irritation and restlessness prevent sleep. They should be given with camphor and the antimonial powder.

When local pains come on, they are occasioned by topical inflammation, and must be treated according to their nature. See INFLAMMATIO.

The diet should be chiefly gruel, or barley water, subacid fruits, water acidulated with lemon, the jelly of currants, or similar sharp fruits. It may be drunk warm or cold, as is most agreeable to the patient. Half a drachm of nitre may be dissolved in every pint of liquor in which no acid juice is mixed. The room should be high, large, and airy. The patient may sit up a little

each day, according to his strength; for this will lessen the fever, headach, and delirium: but when a salutary perspiration comes on, it should be indulged in bed. The sheets may be changed every two or three days, and all putrid matters should be removed.

See Fordyce's Elements of Physic, part ii. Fordyce's Inquiry into the Causes, &c. of Putrid and Inflammatory Fevers.

INFLA'TIO, (from *inflat*, to puff up). See EMPHYSEMA.

INFLA'TUS, (from the same,) is applied botanically to the perianthium, when blown up like a bladder.

INFLO'RESCENTIA, (from *in*, and *floreo*, to blossom,) the mode in which flowers are joined to the plant by the foot stalk.

INFLUE'NZA. INFLUENCE. (Spanish.) See CATARRHUS EPIDEMICUS. The same principle which induced Hippocrates to attribute epidemics to the *æther*, gave this general epidemic catarrh the name of *influenza*. From Sydenham, upwards to Hippocrates, it was known by the name of *catarrhalis febris epidemica*; but Sydenham chiefly calls it *tussis epidemica*: it hath been since variously named, but is now styled *influenza*.

In Dr. Cullen's system it is a variety of *catarrhus à contagio*.

In the year 1673 Sydenham treated of the nature and cure of the putrid fever, which he called *variolous fever*; he found that this fever returned every summer afterwards, and was succeeded by the *cholera morbus* and *bilious fever* (by him called the new fever). In 1675 these fevers were attended by a new symptom, viz. an uncommon degree of stupor, which frequently ended in a coma, and was for that reason by Sydenham called the comatous fever. In the beginning of November of the same year, this fever was complicated with a cough, and was described by Sydenham nearly as follows:

"The fever proceeded in this manner during the autumn, sometimes seizing the head, at others the bowels, every where raging under the appearance of symptoms peculiar to those parts till the end of October; when the weather, which till now had continued in a manner as warm as summer, changed suddenly to cold and moist; whence catarrhs and coughs became more frequent than I remember to have known them in any other season. But it is of most moment to observe, that the stationary fever of this constitution usually succeeded these coughs, and hence became more epidemic, and likewise varied some of its symptoms. For whereas, some little time before, it attacked the head and bowels, now it chiefly seized the lungs and pleura, whence arose peripneumonic and pleuritic symptoms; though it was still precisely the same fever that began in July 1673, and continued without any alteration of its symptoms till the rise of these catarrhs.

"These catarrhs and coughs continued to the end of November, after which they abated, but the fever still remained the same as it was before the catarrhs appeared: though it was neither quite so epidemic, nor accompanied with quite the same symptoms, these depending accidentally upon the catarrhs.

"1675, the season having continued unusually warm, like summer, till towards the end of October, and being suddenly succeeded by cold and moist weather, a cough became more frequent than I remember

to have known it at any other time; for it scarce suffered any one to escape, of whatever age or constitution he were, and seized whole families at once; nor was it remarkable only for the numbers it attacked (for every winter abundance of persons are afflicted with a cough), but also on account of the danger that attended it; for as the constitution, both now and during the preceding autumn, eminently tended to produce the epidemic fever above described, and as there was now no other epidemic existing, which by its opposition might in some measure lessen its violence, the cough made way for, and readily changed into, the fever. In the mean while, as the cough assisted the constitution in producing the fever, so the fever on this account attacked the lungs and *pleura*, just as it had affected the head even the week preceding this cough; which sudden alteration of the symptoms occasioned some, for want of sufficient attention, to esteem this fever an essential pleurisy or peripneumony, though it remained the same as it had been during this constitution, i. e. since July 1673.

“For it began now, as it always did, with a pain in the head, back, and some of the limbs; which were the symptoms of every fever of this constitution, except only that the febrile matter, when it was copiously deposited in the lungs and *pleura*, through the violence of the cough, occasioned such symptoms as belong to those parts. But, nevertheless, as far as I could observe, the fever was the very same with that which prevailed to the day when this cough first appeared: and this likewise the remedies, to which it readily yielded, plainly showed. And though the pungent pain of the side, the difficulty of breathing, the colour of the blood that was taken away, and the rest of the symptoms that are usual in a pleurisy, seemed to intimate that it was an essential pleurisy; yet this disease required no other method of cure than that which agreed with the fever of this constitution, and did no ways admit of that which was proper in the true pleurisy, as will hereafter appear. Add to this, that when a pleurisy is the original disease, it usually arises betwixt spring and summer; whereas the distemper we now treat of began at a very different season, and is only to be reckoned a symptom of the fever which was peculiar to the current year, and the effect of the accidental cough.

“Now, in order to proceed in a proper manner to the particular method of cure, which experience shows to be requisite both in this cough and in those which happen in other years, provided they proceed from the same causes, it is to be observed that the effluvia which used to be expelled the mass of blood by insensible perspiration are struck in, and thrown upon the lungs, from the sudden stoppage of the pores by cold; these by irritating the lungs immediately raise a cough; and the hot and excrementitious vapours of the blood being hereby prevented from passing off by perspiration, a fever is easily raised in the mass; namely, when either the vapours are so copious that the lungs are unable to expel them, or the inflammation is increased by the adventitious heat arising from the use of overheating remedies, or too hot a regimen, so as suddenly to cause a fever in a person who was already too much disposed to one. But of whatever kind the stationary fever be, which prevails the same year, and at the same time, this new fever soon assumes its name, becomes of the same kind, and in most particulars resembles it; though it may still

retain some symptoms belonging to the cough, whence it arose. In every cough, therefore, proceeding from this cause, it is sufficiently manifest that regard must be had not only to the cough, but likewise to the fever that so readily succeeds it.

“Relying on this foundation, I endeavoured to relieve such as required my assistance by the following method: if the cough had not yet caused a fever, and other symptoms, which, as we said, usually accompany it, I judged it sufficient to forbid the use of flesh meats, and all kinds of spirituous liquors, and advised moderate exercise, going into the air, and a draught of cooling pectoral ptisan to be taken between whites. These few things sufficed to relieve the cough; and prevent the fever, and other symptoms usually attending it. For as by abstaining from flesh and spirituous liquors, along with the use of cooling medicines, the blood was so cooled as not easily to admit of a febrile impression, so by the use of exercise those hot effluvia of the blood, which strike in, and occasion a cough as often as the pores are stopped by sudden cold, are commodiously exhaled in the natural and true way, to the relief of the patient.

“With respect to quieting the cough, it is to be observed that opiates, spirituous liquors, and heating medicines used for this purpose, are equally unsafe; for, the matter of the cough being entangled and stiffened thereby, those vapours which should pass off from the blood, in a gentle and gradual manner, by coughing, are retained in the mass, and raise a fever: and this frequently proves very fatal to abundance of the common people, who, whilst they unadvisedly endeavour to check the cough, by taking burnt brandy, and other hot liquors, occasion pleuritic or peripneumonic disorders; and by this irrational procedure render this disease dangerous, and often mortal, which of its own nature is slight, and easily curable. Neither do they err less, though they seem to act more reasonably, who endeavour to remove the cause of the disease by raising sweat; for though we do not deny that spontaneous sweats frequently prove more effectual than all other helps in expelling the morbid cause, yet it is apparent that whilst we attempt to force sweat we inflame the blood, and may possibly destroy the patient, whom we desire to cure.

“But it happens sometimes, not only when the disease has been unskilfully treated, in the manner above described, but also spontaneously, at the beginning of the illness, or in a day or two afterwards, especially in tender and weakly persons, that the cough is succeeded by alternate intervals of heat and cold, a pain in the head, back, and limbs, and sometimes a tendency to sweat, especially in the night; all which symptoms generally followed the fever of this constitution, as it were, of the lungs, which occasioned a difficulty of breathing, stopped the cough, and increased the fever.

“According to the best observation I could make, the fever and its most dangerous symptoms were best relieved by bleeding in the arm, applying a blister to the neck, and giving a clyster every day. In the mean time, I advised the patient to sit up some hours every day, to forbear flesh meats, and sometimes to drink small beer, sometimes milk and water, and sometimes a cooling and lenient ptisan. If the pain of the side abated not in two or three days, but continued very violent,

I bled a second time, and advised the continuance of the clysters. But with respect to clysters, it must be carefully observed; either in this or other fevers, that they are not to be long and frequently used when the disease is in its decline; especially in hysteric women, and in men that are subject to the hypochondriac disease; for the blood and juices of such persons are easily changed, and soon agitated and heated; whence the animal economy is disturbed, and the febrile symptoms continued beyond the usual time.

“But to return to our subject: whilst by these means we allowed time, that the blood might gradually free itself from those hot particles that were lodged in the pleura and lungs, all the symptoms usually went off in a gentle manner; whereas, when the disease was treated in a rough way, by giving abundance of remedies, it either destroyed the patient, or rendered it necessary to repeat bleeding oftener than the disease required, or would safely bear, in order to save life. For though repeated bleeding answers every purpose in the true pleurisy, and is alone sufficient for the cure thereof, provided there be no hindrance from a hot regimen and heating medicines; yet, here, on the contrary, it sufficed to bleed once, or at most twice, in case the patient refrained from bed, and drank cooling liquors. And I never found it necessary to bleed more frequently, unless the symptoms relating to the *pleura* and lungs were much increased by some adventitious heat, and even in this case the practice was not wholly void of danger.

“Upon this occasion, I shall briefly deliver my sentiments with respect to a very trite and common opinion, viz. that a pleurisy is found to be of so malignant a nature in some years that it will not then bear bleeding, at least not so often as this distemper ordinarily demands. Now, though I conceive that a true and *essential* pleurisy, which, as shall hereafter be observed, happens indifferently in all constitutions, does in all years equally indicate repeated bleeding; yet it sometimes happens that the peculiar epidemic fever of the year, from sudden alteration of the manifest qualities of the air, readily throws off the morbid matter upon the *pleura* and lungs, while the fever notwithstanding continues exactly the same. Wherefore, in this case, though bleeding may be used to abate this symptom when it is very violent, yet generally speaking, little more blood ought to be taken away than is required by the fever whereon this symptom depends; for, if the fever be of a kind that will bear frequent bleeding, it may likewise be repeated in the pleurisy, which is a symptom thereof: but if the fever will not bear repeated bleeding, it will be prejudicial in the pleurisy, which will go off with, or last as long as the fever does. And in my judgment this was the case in the symptomatic pleurisy that accompanied the fever which prevailed here at the time the cough began, namely, in winter, 1675; and therefore I must observe, that whoever, in the cure of fevers, hath not always in view the constitution of the year, inasmuch as it tends to produce some particular epidemic disease, and likewise to reduce all the contemporary diseases to its form and likeness, proceeds in an uncertain and fallacious way.

“In the month of November of the above-mentioned year I attended the eldest son of sir Francis Wyndham in this fever. He complained of a pain in his side, and the other symptoms that attended those who had this disease. I bled him but once, applied a blister to

his neck, injected clysters every day, gave him cooling ptisans and emulsions, and sometimes milk and water, or small beer, to drink; and advised his sitting up a few hours every day; and by this method he recovered in a few days, and a purge completed the cure.

“But it must be remarked, that though these were the symptoms which succeeded the cough, during this winter, yet the cough, unattended with these symptoms, was more prevalent at the same time. But this required neither bleeding nor clysters, provided a fever was not occasioned by a hot regimen or heating medicines; it sufficed to allow the benefit of the open air, and to forbid the use of flesh, wine, and such spirituous liquors which are apt to cause a fever.” Wallis’s Sydenham.

In the month of July, 1775, the putrid fever, came on; was succeeded by the cholera morbus in August, and the bilious fever in September, as usual; this bilious fever, however, was attended with a degree of stupor, which went off with the other symptoms when properly treated; but was easily turned into a coma, when improperly treated at any period of the disease. See Dr. Grant’s Account of the Epidemic Cough and Fever, 1776, from Sydenham.

This subject hath engaged the attention of many since the year 1775; and in 1782, Dr. J. C. Smyth gave his observations of this disorder, in the first volume of Medical Communications, p. 71, &c. the substance of which is as follows:

“The late influenza was very generally accompanied not only with the usual catarrhal symptoms, but with others no less distressing to the patient, and which were still more alarming to the physician; such as great languor, lowness, and oppression at the præcordia; anxiety, with frequent sighing, sickness, and violent headach. The pulse was uncommonly quick and irregular, and the sick were frequently delirious, especially in the night. The heat of the body was seldom considerable, particularly when compared with the violence of the other symptoms; the skin was moist, with a tendency to profuse sweating; the tongue white or yellowish, but moist. Some persons complained of severe muscular pains either general or local, others had erysipelatous patches or efflorescences on different parts of the body, which in one instance terminated in gangrene and death. I observed petechiæ but once, and then only two days before death. Those attacked with the influenza were in general taken suddenly ill, and the symptoms in the beginning, or for the first twenty-four or forty-eight hours, were extremely violent, bearing no proportion either to the danger or duration of the distemper. Children and old people either escaped entirely, or were affected in a slighter manner. Women with child, when seized with the disease, were apt to miscarry; or, if far advanced in their pregnancy, to be delivered before their time; in either case, the hæmorrhage was considerable, and several died. Patients subject to pulmonic complaints suffered much from the cough, difficult breathing, and other peripneumonic symptoms, and to them also the disease proved dangerous or fatal.

“The headach which accompanied the influenza may be distinguished into three kinds.

“1st. The uneasy weight, soreness, and distention, of the forehead, usual in common colds.

"2dly. The violent sick headach, arising from the affection of the stomach, and relieved by vomiting.

"3dly. The headach, during which the patients complained of a sensation as if their head was splitting, with a severe shooting pain at the vertex; this last headach was most usual in peripneumonic cases, and seemed chiefly occasioned by the violence of the cough.

"The fever began with irregular chilliness, had considerable exacerbations and remissions, and was always greatly increased towards night; but even then the heat of the body and thirst were seldom so great as might have been expected, and the accessions of fever were chiefly marked by the increased quickness of pulse and delirium. The frequency of the pulse was greater than is common in fevers; (it was often 120, even in the remissions of fever, in the accessions 140, and sometimes so frequent that it was impossible to reckon it: in many instances it was irregular and intermitting;) nor do I remember to have felt so frequent, and at the same time so irregular, a pulse (the irregularity of the pulse is in a great measure characteristic of malignant contagious fevers), in any fever attended with so little danger, and of so speedy and easy a termination; the violence of this being commonly over in twenty-four or forty-eight hours. Many, from the beginning, were delirious in the night time and during the exacerbation of fever, who were perfectly recollected and distinct in the day and during the remissions; but even where the delirium continued, it was not a constant one, as the sick knew those who spoke to them, would answer some questions distinctly, and a few minutes afterwards talk incoherently; a fixed stare of the eyes at the time, and a kind of wildness in the countenance, were also very expressive of this state or condition. The delirium which we have just now described, though unnoticed (so far as I know) by any practical writer, is not unusual in the putrid fever, and differs as materially from the low delirium incident to the last stage of that disease, as it does from the phrenetic delirium of the febris ardens, or of any inflammatory fever. During the whole of the influenza, I met only one instance of true phrenetic delirium; and it may not be foreign to the purpose to remark, that it happened to a patient who had been three times bled, had swallowed no heating cordials, and who was taken every day out of bed, conformable to the judicious practice of Sydenham (vid. *De Febre Comatosa*), expressly with the intention of preventing this termination of the disease. Respecting the danger of the influenza, physicians, I find, have entertained somewhat opposite opinions; possibly owing to the difference of place and situation. In London, although the distemper doubtless proved fatal to many, yet it could hardly be accounted a dangerous one, if the number who died be compared with the prodigious number of those who recovered.

"The late influenza might very properly have been named the sweating sickness, as sweating was the natural and spontaneous solution of it, and rest, abstinence, and warm diluents, were, in most instances, all that were necessary for the cure; yet, amidst such an amazing number and variety of cases, many occurred which required some further medical assistance, and when that became necessary, it was of the utmost importance that it should be procured early; for the disease when neglected or improperly managed in the beginning, some-

times ended in a malignant fever of difficult treatment, and of very doubtful termination. And although the tendency to profuse sweating often continued, it now only weakened the patient, and a critical or salutary solution of the disease, in consequence of this evacuation, was no longer to be expected; nor do I recollect a single example of profuse sweating being attended with any advantage after the first forty-eight hours.

"The medicines which I found most serviceable in abating or carrying off the fever were small doses of an antimonial powder, composed chiefly of tartar. emet. the julep e camphora, with about a fourth part of the spt. Mindereri; the common saline draught, with ten or fifteen grains of the pulv. contrayerv. c. or, what I commonly preferred, from twenty to forty drops of the liquor anod. min. Hoffmanni, adding occasionally a small quantity of the paregoric elixir.

"In cases of great lowness, besides the drinks and nourishment usual in fevers, I allowed the sick white wine whey, wine and water; and weak veal broth.

"For removing the oppression at the præcordia, sickness, and headach, no means were so certain as vomiting with tart. emet. giving it in small doses, largely diluted, and repeated every ten or fifteen minutes, until it produces the desired operation. This medicine, administered in this manner, had also a very remarkable effect in bringing on a remission of the febrile symptoms, and in accelerating the termination of the disease. It likewise commonly opened the body; when that was not the case some gentle laxative was given.

"The cough required not only plentiful warm dilution, but opiates and blisters were also very necessary; and where the sick were attacked with stitches, or acute pains about the chest, with difficult or laborious breathing, and other peripneumonic symptoms, the propriety of bleeding was, in my opinion, clearly and evidently pointed out; nor can I think any physician justifiable in neglecting the use of the lancet under such circumstances. At the same time, I am ready to acknowledge, that bleeding, though necessary to obviate the fatal consequence of a particular symptom, was by no means conducive to the general cure of the disease; that, on the contrary, the lowness and dejection were often increased by it; that the blood taken away had not always an inflammatory appearance, but was sometimes florid, and the crassamentum tender; that the relief afforded by bleeding was neither so considerable nor so certain as in other similar cases of peripneumony, and that in the course of the disease there frequently appeared unequivocal signs of a putrid tendency. But admitting the whole of these facts, and granting that they ought to make a physician cautious of taking away blood so freely, perhaps, as he otherwise would do, and as the urgency of the symptoms might seem to justify, yet they surely do not lead to an entire prohibition of the use of the lancet, at least in those cases where there was evidently no alternative, and where, although the effects of bleeding might be doubtful, the consequence of omitting it was certain. Upon such occasions, the advice of Celsus is the voice of reason, "Sautus est enim anceps auxilium experiri quam nullum." Besides bleeding, blisters applied as near as possible to the parts affected were here, as in similar cases, of very essential service in removing the stitches in the side, and in relieving the difficulty of breathing; so that we may

justly apply to them what an eminent author said of the Peruvian bark, that he found it most serviceable where it was most wanted; for in cases purely inflammatory, where bleeding of itself will commonly do every thing, blisters are less necessary; but in those of a mixed nature, where the assistance of blisters is more immediately required, the relief afforded by them is in general more certain.

“Some may think it strange, that amongst the remedies employed in the treatment of this disease I have made no mention of oily medicines, such as emulsions, linctuses, &c. nor of the Peruvian bark. In regard to oily medicines, I have often observed that the advantage derived from them in cases of catarrh, attended with heat and fever, was extremely equivocal; and that wherever there were nausea, oppression, and uneasiness at the stomach, with a bitter taste in the mouth, and nidorous eructations, they did more harm than good: as these symptoms so frequently occurred in the influenza, I thought it safest to omit their use entirely.

“As to the bark, I shall only remark, that in the influenza, the cough, affection of the breathing, and oppression at the præcordia, where they occurred, were to me sufficient reasons for not employing it; and that even where these symptoms were not present, and in cases where the great lowness, and apparent putrid tendency, seemed not only to justify but even to demand the use of the bark, I never was so fortunate as to see one single instance where it produced any sensible good effect, either in moderating the fever, supporting the strength, checking the disposition to gangrene, or in preventing the fatal catastrophe that ensued.

“When the fever, and other immediately alarming symptoms of the influenza had ceased, there frequently remained a teasing cough; and convalescents in general complained of languor, want of appetite, and that their sleep was interrupted and unrefreshing. For removing these complaints, and completing the recovery of the patients, change of air, and riding on horseback, were the most effectual remedies; and to some they were absolutely necessary. A milk diet was recommended where the cough was obstinate; but I did not find it either necessary or of advantage to enjoin so strict an antiphlogistic regimen as is usually done in similar complaints. Neither do I know of any instance where the cough terminated in a phthisis pulmonalis, and I am much inclined to believe that this fatal termination was much less frequent after the influenza than after a common cold. For the lowness and want of appetite, chalybeate waters, especially when drunk at the spring, were of singular service. I also frequently prescribed, and I think with advantage, the elix. vitr. cum liquor. anod. Hoffmanni, taken to the quantity of thirty or forty drops in a bitter infusion, or in a decoction of the bark.

“In this short account of the late influenza, I have offered no conjecture with regard to the original cause of the distemper, or the manner in which it was propagated. I apprehend, from the present state of our knowledge, that we can hardly venture to say even what it is not; still less to affirm, with any probability, what it is.”

Having thus inserted the best accounts, both ancient and modern, we shall refer for our own opinions and experience to the article CATARRHUS EPIDEMICUS.

See also Observations on the Influenza by A. Brough-

ton, M. D.; a Description of the Influenza, by R. Hamilton, M. D.; Fothergill's Works, by Lettsom, 4to. p. 615; Medical Observations and Inquiries, vol. vi. p. 340, &c.; Medical Transactions, vol. iii. p. 54, &c.; Medical Communications, vol. i. p. 1, &c.; Edinburgh Medical Commentaries, vol. ix. p. 393; Memoirs of the Medical Society, vol. i. to vi.

INFRASCAPULARIS MUSCULUS, (from *infra*, below, and *scapula*, the shoulder blade,) *infraspinatus*, *superscapularis inferior*, *subscapularis*, or *immersus*, rises from the whole inner surface of the scapula, passes under the coracoid process, runs over the capsular ligament, and is inserted into the outer tuberosity of the os humeri, carrying the arm round, and partly raising it—being the reverse of the supraspinatus.

INFRASPINA'TUS, (from *infra*, and *spina*.) See **INFRASCAPULARIS**.

INFUNDI'BULUM, (from its shape,) *choana*, *pelvis*, *chond.* Between the basis of the anterior pillars of the fornix, and the anterior part of the union of the optic thalami, lies this funnel-like cavity. It runs down towards the basis of the cerebrum, contracting gradually, terminating in the glandula pituitaria, and communicating with the lateral ventricles. (See **CEREBRUM**.) The name also of the pelvis of the kidneys (see **RENES**,) and of the pharynx.

INFUSIO, (from *infundo*, to pour in.) **INFUSION**. It signifies either the action of the fluid, or the medicine prepared by it.

By infusion in water, the gummy, the extractive, and the saline parts of vegetables, are separated: and by the intervention of the gum, the resin and oil are in part taken up by the same menstruum, so that in many instances the whole virtue of a plant is obtained. In general, water takes up more by infusion from dry herbs than from fresh ones, particularly the newly dried ones. From animal substances, water extracts the gelatinous and nutritious parts; and by this means glues, jellies, and broths, are prepared; and along with these it sometimes takes up principals of more activity. Water also generally suspends some portion of calcareous and aluminous earth; the quantity it dissolves of either is truly inconsiderable.

In making infusions, whether in cold or hot water, the ingredients are only steeped in it, without boiling. It is the same, whether proof spirit, rectified spirit, or any other menstruum, is employed, though these preparations have a different title. This form is preferred where the medicinal portion is soluble and easily separated; when it is volatile, and would fly off by boiling; or where it would be lost or destroyed by long maceration.

In nervous disorders, infusions are best made in a vinous, a spirituous, or an alkaline menstruum. Stomachic infusions should be moderately spirituous. Cathartic ones, whether saline or resinous, if for extemporaneous use, are best made with hot water.

Infusions should not, if possible, be so fully impregnated with the ingredients as to make the medicine unpalatable: though the infusions of many of the fetid plants must be necessarily unpleasing.

Many infusions are most agreeable when made with cold water, though probably weaker than when heat is employed. The cold infusion of camomile flowers and the *carduus benedictus* are pleasant, and will not excite vomiting.

INFU'SIO. See TRANSFUSIO.

INFU'SUM. AN INFUSION. Sometimes styled *ditutum*; at others it means a clyster or an injection.

INGE'STA, (from *ingero, to throw in*). The contents of the stomach; generally alimentary, sometimes medicinal.

INGRAVIDA'TIO, (from *ingravidor, to be great with child*). See IMPREGNATIO.

IN'GUEN, (from *εγγυω, to bring forth*). The groin. The two groins are the lateral divisions of the hypogastric region.

INGUINA'LIS; (from *inguen, the groin*; so called from its supposed efficacy in diseases of the groin). See ERYNGIUM.

INHALA'TIO. See FUMIGATIO.

INHA'LER. An instrument recommended by Dr. Mudge for the cure of catarrhs, but now disused, though it may be in many cases probably advantageous.

INIHAMÆ ORIENTA'LES. See BATATAS HISPANICA.

INHAME. See CARA BRASILIENSIBUS.

INHUMA'TIO, (from *inhumo, to bury in the ground*). A method of digesting, by burying in horse dung the vessel which contains the chemical ingredients to be digested.

INIMBOI'A. See BONDUCH INDORUM.

IN'NION, (the place whence *ives, the nerves*, originate). See OCCIPUT.

INJACULA'TIO, (from *injācular, to shoot into*). A violent spasmodic pain in the stomach, feeling as if darts were shot into it, with an immobility of the body. Van Helmont.

INJE'CTIO, (from *injicio, to throw into*). AN INJECTION, called also *eisbole*. Fluids used for injection should be used lukewarm; and may be applied either by a syringe or clyster pipe.

When used in glects or gonorrhœas, Dr. Swediaur advises that the syringe should have a short but wide pipe, so large that its orifice may enter the urethra, and the piston be close to its sides. If the whole pipe of the syringe be much smaller than the orifice of the urethra, it may wound the inside of the canal, and admit the poison by absorption, or the liquid run out sideways, instead of passing into the urethra. If the piston itself does not apply closely to the sides of the syringe, even if the pipe is sufficiently large, so that it perfectly closes the orifice of the urethra, the liquor will still regurgitate between the piston and the syringe, and very little of the fluid will pass. The syringe being properly made, should be applied closely and exactly to the orifice of the urethra; so that, by the conic form of its pipe, all passage may be denied to the liquid betwixt it and the sides of the urethra. If the disorder lies in the usual original seat of gonorrhœas, viz. just under the frænum, the patient should, with one hand, compress the urethra at the first curvature of the penis, where the scrotum begins, while he holds and manages the syringe with the fingers of the other. The piston, which should always go close and easy, ought then to be pressed softly and slowly, till he feels the urethra gently dilated, and thus keep the liquid injected for a minute or two in the passage, repeating the same operation three or four times. By a rash or longer continued pressure of the piston, the irritation often does considerable injury. By attending to these directions, the liquid is properly

applied to the part affected, and no danger is incurred of carrying some of the venereal poison farther into the urethra with the injected liquid. This precaution is, however, not very necessary, as the dilution will prevent any injury. The liquid should always, in cases of virulent gonorrhœa, be lukewarm; but in glects, cold. In gonorrhœas, if the liquid is too cold or too warm, it is supposed likely to hurt the patient, either by the retropulsion of the matter, or increasing the inflammation. In all cases, before an injection is applied, the patient should attempt to make water. There are a variety of injections made use of in this complaint; among the most efficacious are the following:

INJECTION OF ACETATED AMMONIA. To three ounces of distilled water add one ounce of acetated ammonia.—OF ACETATED LITHARGE. To four ounces of rose water add eight drops of acetated litharge.—MURIATED INJECTION. To four ounces of distilled water add eight drops of muriatic acid.—OILY INJECTION. To four ounces of oil of almonds add eight drops of acetated litharge.—OPIATE INJECTION. To four ounces of distilled water add forty or sixty drops of tincture of opium.—INJECTION OF GREEN TEA. Infuse half an ounce of green tea in four ounces of boiling water, and let it stand till cold.—COMPOUND INJECTION OF CERUSSA, see PLUMBUM.—INJECTION OF MURIATED QUICKSILVER. To four ounces of distilled water add two drops of the liquor of muriated quicksilver. This must be weakened if the inflammation in gonorrhœa is great: or, should there not be any, it may be strengthened. Any of these may be used in the inflammatory stage of a gonorrhœa; but the muriated is considered as the most eligible, where the scalding of urine is very troublesome.—INJECTIONS OF VITRIOL OF ZINC. Dissolve ten grains of vitriol of zinc in five ounces of water.—COMPOUND INJECTIONS OF VITRIOL OF ZINC. Add to the above ten drops of acetum lythargyri, or half a drachm of white vitriol, with as much acetated lead, a drachm of camphor, and two scruples of opium, are dissolved in sixteen ounces of boiling water, and strained.—MERCURIAL INJECTIONS. Mucilaginis gum arab. $\frac{3}{4}$ iv. calomelanos $\frac{3}{4}$ ss. or hydrargyri purificati $\frac{3}{4}$ i. mucilaginis $\frac{3}{4}$ iss. aq. $\frac{3}{4}$ iss. As astringent injections the following are recommended: INJECTION OF ALUM. Dissolve four grains of alum in four ounces of rose water.—OF COPAIBA. Mix two drachms of balsam of copaiba with six ounces of rose water, by means of the yolk of an egg; or, with four ounces of lime water, by means of the mucilage of gum arabic; of ACETATED COPPER; of AMMONIATED COPPER; of VITRIOLATED COPPER; COMPOUND INJECTION OF VITRIOLATED COPPER. (See CUPRUM.) These are beneficial in the last stage of gonorrhœa; glects; fluor albus; and, perhaps, with small portions of their active ingredients may be employed in the inflammatory stage as sedatives. INJECTION OF GALLS. See GALLÆ.

Patients who labour under glects, after having used injections with some advantage, grow careless in the application, and even sometimes neglect them for a day or two. The consequence of this has been that the discharge has increased, as if it had been a fresh disease; and the relapse being more obstinate than the original complaint, the patients have been obliged to continue the injections for more weeks than it might have required

days had their use not been interrupted. In general, to prevent all danger of a relapse, it is proper to employ the injections three, four, or, according to circumstances, six times a day during the disease, and to continue the same regularly for ten or twelve days after the running has entirely ceased.

In ANATOMY great improvement hath been made by means of injections. Ruysch first employed them with success; and it is said that the Czar Peter, seeing an injected boy, whose appearance nearly resembled life, ran and kissed it.

Injections, which unite with water, and consequently with the animal fluids, consist of isinglass and common glue. These succeed with the finer vessels, in membranes; but, if employed to fill the larger, they take too long time in coagulating. If coagulated by alcohol, they become brittle; and, when the water is carried off by evaporation, the vessels are not properly filled. It has been attempted to remove these inconveniences, by first injecting the solution of glue; and, when the capillary vessels are filled, a coarser wax injection; but the wax either hardens too soon, mixes irregularly with glue, or the parts separate where the two fluids are in contact.

Alcohol mixes both with water and oil, and consequently has been employed to fill the capillary vessels, but it coagulates the animal fluids it meets, and often blocks up the canal. It will not suspend durably coloured powders, and, at last, evaporates, leaving little more than the colours of those to which it had been united. Melted tallow, with a little mixture of oil, is often useful; but it sometimes stops too soon, where it meets with animal fluids, and becomes, by time, very brittle. Oil of turpentine, recommended by Dr. Monro, is generally employed to fill the finer vessels. It suspends the colouring matter; and, when the more volatile parts are evaporated, enough of the grosser particles remain, to retain the powder, and keep the vessels sufficiently full. After this is injected, it is confined by filling the larger vessels with a coarser injection, with which it unites very accurately.

Anatomists have preferred for the colour of their injections such pigments as most nearly imitate the natural contents of the vessels; the red for the arteries, and the blue for the veins. The vegetable colours are apt to concrete, and are destroyed by insects. The mineral are therefore preferred. The red is generally vermilion, a substance which in a small proportion gives a very considerable body of colour; and the green consists of distilled verdigris, which is brighter than the common sort, and dissolves in oil; the blue of verditer or smalt; the yellow of king's yellow; the black of lamp black or burnt ivory are used.

The properties required in the injecting matter are fluidity; and they must likewise grow stiff, but tough and flexible when cold; for were they too hard the smaller vessels would be frequently broken. The following possess these properties:

FINE INJECTION. *By Dr. Nicholls.*—Take hard white Spanish varnish, and hard brown Spanish varnish, of each equal parts; turpentine varnish and vermilion, of each a sufficient quantity. Mix them.

COARSE INJECTION. *By Dr. Nicholls.*—Take of yellow resin two pounds; of yellow wax one pound; of turpentine varnish a sufficient quantity.

These injections may be coloured with vermilion or with verdigris. Whatever colouring matter is used, it must be ground extremely fine.

Dr. Monro recommends for the fine injection a pound of oil of turpentine, gradually poured on the colouring matter finely powdered. To procure the vermilion or verdigris very fine, it may be agitated with the oil, and, after standing at rest a little time, poured off; the coarser parts will by that means be separated, as they will have subsided.

Dr. Monro's coarser injection consists of tallow one pound, white wax five ounces, common oil three ounces, melted over a lamp, adding Venice turpentine two ounces. When this is dissolved, the whole must be strained through a warm linen cloth; and, if designed to run far, some oil of turpentine must be added when it is used. The fine injections, it is said, should be thrown in as warm as the finger can well bear; the coarser nearly at the boiling point. In general, however, these directions are erroneous; for, by such heats, the colour will be changed, and the coats of the vessels injured. It will be safer to give them only so great a degree of heat as is sufficient to render them perfectly fluid.

Quicksilver is frequently used for injections, and it is excellently adapted for this purpose, from its admitting of the minutest division. Were it possible to render it solid, and to impart to it any given colour, its advantages would be very considerable. May it not be possible to oxidate it within the vessels? Its great fluidity is, however, inconvenient, as the slightest puncture empties all the vessels filled with it; and its weight renders the preparation so heavy, that it is liable to strike against the glass, and to rupture the distended vessels. In injecting with quicksilver no impulse of a piston is necessary, for its own weight is sufficient; but the operator must recollect, that the momentum is in proportion to the perpendicular height of the column, not its diameter. Quicksilver is chiefly used in injecting the lacteals and lymphatics, the vessels of the parotid glands, of the testis, and of the mammæ, sometimes the arteries and veins of the hand.

In general, the younger the animal is the injection will go farther, and the same will happen when the fluids have been exhausted by disease. In the first case, the small vessels are larger; in the second, they are more empty. The less solid the part is, more vessels will be filled; and the more membranous, the brighter and more beautiful the preparation will appear. The great object in injections, therefore, is, to empty the vessels, to relax the solids, and prevent the too rapid coagulation of the injected fluids. Water is, therefore, first injected, till it returns colourless by the veins; the water is propelled by injecting air, and the air is afterwards squeezed out. But the water cannot be wholly separated, and the particles of this fluid interposed between those of the injection occasion its breaking. It is, therefore, more common to trust to maceration for some time in the water, and squeezing the vessels, so as to evacuate the fluids by the divided end.

It is not easy to detail with advantage, in this place, the minuter regulations of this operation. It must be learnt from the works of practical anatomists, and from experience. The arterial system, after death, is usually empty; and the injection runs freely through it. To

inject the veins from the trunks the valves must be forced, which is difficult, and generally impossible; for the coats will yield rather than the valves, so that one of the smallest branches which will admit the pipe must be opened. It must be recollected, however, that the veins of the abdominal viscera have no valves, so that they may be injected in any direction.

The subjects to be injected, after having their vessels cleared of their contents, should be warmed in water.

A fœtus may be injected by the umbilicus; a child by the aorta ascendens from the left ventricle; an adult in the same manner as a child. Injection by the aorta fills only the arteries; but by the umbilicus of a fœtus both arteries and veins are injected. When the arteries in the cornea are filled, the injection should not be pushed farther. When finished, the subject should be cooled suddenly in cold water.

If the body is macerated a day or two in cold, before it is put into warm, water, the blood will be more effectually dissolved, and the vessels more effectually emptied than by any other method. When put into warm water it may continue thirty-six or forty-eight hours, the water being kept as hot as one can bear a hand in it.

A preparation is best dried by a current of free air, avoiding dust; when dry, it must be varnished. The shining varnish may be laid on it with a brush. While drying, if animalcules appear, the part may be wetted with a solution of hydrargyrus muriatus dissolved in rectified spirit of wine.

Muriatic or nitrous acid diluted is proper for destroying the soft parts of injected preparations.

The rectified spirit of malt is the best for preserving these or any other anatomical preparations.

INIRRITANTIA. This is a class of medicines not hitherto introduced into the systems of therapeutics, though described, we apprehend, by Dr. G. Pearson, in his course of the *Materia Medica*, under the appellation of *acentropoetics*, from α , a privative, and $\kappa\epsilon\upsilon\tau\pi\omicron\upsilon\varsigma$, stimulus, a term we might have adopted, had it occurred to us in an earlier stage of the work. The great doubt which remains is, whether this be not properly a subdivision of sedatives. We think that strictly it is so; and we noticed these medicines in the article **ANODYNES**, q. v., but thought it would be useful to the younger student to bring the whole subject into one view, as its application is extensive, and utility considerable.

The sources of irritation in the human body are numerous. Of this kind are external stimuli; acrimony in the first passages, or the secreted fluids; inflammatory stimulus, particularly of the mucous membranes; scirrhi, or other indurations; extraneous substances lodged in the cellular membrane, or among the fibres of the muscles; worms, ossifications, or extravasated blood. The remedies of these irritations occur under their proper heads; and it is rather the object of this article to speak of the nervous irritations more generally, whose source is less obvious.

Nervous excitement often arises from a particular state of the nervous power, or, as we may be allowed to style it, the nervous fluid. Whatever be the state which causes animation, the increase of that energy is irritation. This irritation, according to its different circumstances, is allayed by cold, by heat, by exhausting the nervous power, or, more directly, destroying its

activity; by diluting, and thus diminishing the activity of its cause; by sheathing the nerves from its action, or discharging it.

Cold we have already spoken of; and the sedative power of this remedy, either by its continued effect or its repetition, has been already explained. It properly belongs to a subsequent head, but it is distinguished in this place in consequence of its application. It is particularly adapted to the increased excitements which produce a more active circulation, either in general or in particular organs; in general, chiefly in hæmorrhages, and locally, in those inflammations which rapidly destroy the texture of the part, or produce atony, from excess of stimulus. It is thus one of the most ready and powerful inirritants that we employ.

Heat. The regulation of temperature, in a different way, is often effectual in lessening irritation, viz. by the continuation of a degree somewhat lower than that of the body, and much lower than that of the affected part. Thus water of the heat of 92° to 95° gradually soothes the irritated nerve, and lessens its excitement. Air acts more slowly, and, of course, less effectually; for the application even of the water must be long continued before it produces any effect. To their warmth a variety of demulcent remedies owe their efficacy, but often to their other qualities, which we shall soon notice.

Exhausting the nervous power, by stimulants, somewhat below in their effects those of the irritating cause, is often effectual. By this our object is to continue the excitement, not in a morbid degree, but by diminishing its power to exhaust safely the irritability of the nerve. Thus volatile alkali and eau de luce succeed in lessening the fatal effects of the viper's poison; alcohol and turpentine relieve burns; mercury sometimes lessens the irritation of the hydrophobic poison, and perhaps partly in this way of the lues venerea. We were long since taught to prevent the trismus expected to arise from the puncture of a nerve, by applying ethereal spirit of turpentine. Many similar remedies are employed, and this is one of the most successful refinements of modern practice.

In a similar way *we destroy the activity of the nervous power* by sedatives; by tonics, which lessen irritability; and by narcotics. We lessen irritation by opium and by vinegar; by bark and other vegetable astringents; by lead, copper, zinc, and silver. The narcotics we employ are tobacco, belladonna, hemlock, and digitalis. Each is useful in this way.

We sometimes lessen irritation by *diluting the stimulus*, and this is necessary when acrid poisons are carried to the excretories, as cantharides to the bladder, or when saline acrimony abounds in the blood. Dilution is, however, most often necessary when acrimony abounds in the primæ viæ; a more frequent occurrence than any other of this kind.

The diminution of irritation by *sheathing the parts*, and thus defending them from acrimony, includes the class of demulcents. This class is of considerable extent, and the medicines we shortly enumerated in that article. They are the oils and fats in all their variety, including spermaceti and bees wax; the pure mucilages, including the gums and althæa; the farinaceous mucilages, as the lint and hempseed, the quince and fenugreek seeds; the fecula of wheat, and some miscella-

neous vegetables, as the branca ursina, the melilot, the white lily, &c. We can easily conceive that these can sheath the fauces, the epiglottis, the stomach, and intestines; but it is more difficult to suppose that they can be carried into the blood, and again act on the excretory vessels. This is, however, undoubtedly true, and we see it certainly in the urinary organs, probably in the lungs. These demulcents, like warm water externally, seem to sooth irritation beyond the part to which they are applied; for such is the consent of the small vessels on every portion of the surface with each other, that changes produced in one part are, by sympathy, communicated to the whole.

The medicines which discharge the acrid matter can scarcely be enumerated among these; for puncturing a furunculus cannot be styled an irritant. It was mentioned, however, to connect the whole, and to suggest that a source of irritation in distant parts is often productive of great inconvenience. When violent symptoms of irritation, therefore, appear, of which the immediate cause is not perceived, it will be necessary to extend our views to every part of the body; and we may thus be able to discover and discharge substances which have been unnoticed, and produced, without suspicion of the cause, the greatest inconveniences.

We have confined, in this view, the action of irritants to cases of excitement; yet we shall find other sources of irritation from privations. Thus, hunger produces symptoms of irritation; the want of the usual distention in any of the cavities, and fatigue, have a similar effect. The only remedy in common to both these causes of irritation is warmth, or particularly warm water: but it is unnecessary to enlarge at present on this subject; since to add the remedies of this kind would render the class less natural, and we should anticipate what will occur under another article. See IRRITATION.

INNOMINA'TA ARTE'RIA, (from *in*, *non*, and *nomen*, a name). This word is applied to any part that has no specific denomination. It is the external branch of the external iliac artery at its division, near Poupart's ligament, ascends outwardly to the inside of the spine of the ilium; is lost in the muscle of the belly, and sends branches to the ileus internus.

INNOMINA'TI NE'RVII. A name of the fifth pair. See TRIGEMINI NERVI.

INNOMINA'TUM OS. *Coxæ ossa, os ilii, or coxendix*. The principal bone of the pelvis.

INNUTRI'TIO, (from *in*, *not*, and *nutrio*, to nourish). See ATROPHIA.

INOCULA'TIO, (from *inoculo*, to engraft). See VARIOLA and VACCINA.

INOSCULA'TIO, (from *in*, and *osculum*, a little orifice). See ANASTOMOSIS.

INPINGUE'DO PO'RCI. See COSTUS.

INSA'NIA, (from *in*, *not*, and *sanus*, sound). DELIRIUM, or MADNESS. See MANIA.

INSE'CTA, (from *in*, *into*, and *seco*, to cut). AN INSECT. These animals are thus named from their being almost wholly divided in the middle.

We deferred considering this class of animals in a physical or a medicinal view when we treated of the ANIMAL KINGDOM, q. v., because we had not received the last labours of Cuvier and La Treille. Insects

were most strictly distinguished by Lyonnet, who styled them animals without any vertebræ, with articulated paws or limbs. The flesh is soft, but the skin hard, scaly, or crustaceous, to which the muscles are attached; though the true crustaceous animals should be separated from insects, as having a muscular heart, and breathing by means of gills. See CRUSTACEA.

Another distinction of insects is their colourless blood. If some insects are bruised, a red fluid is discharged; but this has, in general, no relation to blood, except when blood has been previously swallowed; and in some insects it is a secreted fluid under the eyes. Yet, from the late observations of Cuvier, red blood seems to occur in some animals of this class.

The arrangement of insects is scarcely the object of this work. We may, however, remark, that they have been considered for this purpose in all their varied relations. Swammerdam has preferred, as the basis of his classification, their metamorphoses; Linnæus the organs of motion; Fabricius those of nutrition. The system of Linnæus is certainly the best and most natural; yet later observers have found some inaccuracies in his characters, and less exact distinction in his apterous insects. De Geer and Olivier have lessened these inconveniences by stricter discriminations, and forming a new order, the *orthoptera*, taken from the *hæmiptera*. Indeed, we consider Olivier's arrangement as the best and most natural; more simple than Latreilles, more correct than that of Fabricius.

Insects may be considered in a work like the present as articles of food, as medicinal bodies, as either useful or detrimental to mankind. If we except the crustacea, we shall find few species used at any time as aliment. The locust (*gryllus cristatus* Linnæi) is used in the east as food. It is said to taste like a pigeon, but more insipid, and is seldom eaten but when other food is scarce. Its price is high only in times of famine. The wings and feet, sometimes the intestines, are separated. The Bedouins of Egypt eat them roasted alive; the Arabians roast and eat them with butter; or, when they wish for a dish of peculiar delicacy, they parboil, and then fry them in butter. The inhabitants of Morocco dry them, and those of Barbary pickle them. Forskal, however, tells us that they have very little flavour, and that they are far from nutritious, and occasion melancholy, or cutaneous affections. In different parts of India and America the larvæ of coleopterous insects, bred in the internal parts of trees, as the weevil, a species of lucanus, the passalus of Fabricius, the prionus cervicornis, &c.; but these can only be procured with much trouble, and can never form an article of food. We have heard of the worms of filberts being eaten as a delicacy, and said to be rich, like marrow, with the taste of the nut, and that the maggots of every fruit have its peculiar flavour. The Romans used to eat the larva of an insect which they styled *cossus*, supposed to be the same which is found under the bark of the willow or the ash; but this larva, which is a true caterpillar, has an insupportable smell and probably a disagreeable taste; so that it is certainly not the same. In Africa the inhabitants eat the white ants. The galls formed by a cynips on a species of sage in the isle of Crete, and on the *glechoma hederacea* Linnæi, are accounted by children a peculiar delicacy. The honey of the bee is too well known as a

nutritious substance, and a medicine to be particularly noticed. The honey of some districts in America is, however, poisonous (see American Transactions); and new honey will often disagree with the bowels, when these are peculiarly tender and irritable.

If, with much trouble, we have collected a scanty catalogue of nutritious insects, we shall not find the materia medica greatly enriched from these minute animals. The cantharides are, however, of considerable importance in medicine (*vide in verbo*); and the ants are said, by infusion, to furnish a pleasant and salutary acid drink in fevers. (See FORMICA.) The galls of the oak and the bedaguar of the rose tree, though the effects of insects, derive all their virtues apparently from juices of the tree and vegetable. The carabus, chrysocephalus, two species of the sphæx of Linnæus, two of the chrysomela and coccinella, three of the curculio, have been recommended in tooth ach. The insects are to be bruised between the fingers, and the tooth and gums rubbed with the same fingers. The meloe majalis and proscarabæus are of the nature of cantharides, but less powerful. The oniscus asellus (millepes) was formerly much employed as a stimulating expectorant in dropsy, in obstructions of the liver, in asthma, and cyanche. Its nauseous acrimony points it out as a medicine of importance; but its disgusting appearance has occasioned its neglect. The coccus of the cactus coccinelliferus (cochineal) is said to be stimulant and diuretic; the same insect of the ficus Indica, and quercus ilicis, the lac, and kermes, to be astringent; but modern practice neglects both. We have said that the more refined naturalists had separated the spiders from the insects; but we may mention here, without an apology, the use of the spider's webs in external hæmorrhages, which act in assisting the concretion of the blood. We mention it also to add, that an ant found in Cayenne, the formica fungosa of Fabricius, composes its bed of a down so fine, that it generally succeeds in stopping arterial hæmorrhages on the same principle. The ancients used the horns of the cervus volans as an absorbent; and Linnæus tells us, that in Sweden a species of gryllus is irritated so as to bite warts, and that the fluid from its mouth destroys them. The trivial name is assigned from this property.

Among the advantages derived to mankind from insects, we need not name the silk, and the scarlet dye from the cochineal. Many insects, besides that of the mulberry, spin a silken pod; and from many of the cocci, a brilliant colour, though inferior to that of the cochineal, may be obtained. From the silk worm's pod, the Chinese, it is said, prepare a brilliant and durable varnish. This worm affords also the Bengal root, styled in England Indian grass, so useful to the fisherman. We need not add Reaumur's attempt to make silk from spider's webs, in which it has been supposed he would have succeeded, could he have induced them to live peaceably with each other. The gum lac and bees wax are well known, and some naturalists have attributed amber to these animals. Among the advantages of insects to mankind, we may also reckon their furnishing birds with a copious supply of nourishment, and their destruction of putrid matter and of each other.

The chief disadvantages are derived from their destructive ravages on books and furniture, and, above all,

from the diseases which they occasion. (See ANIMALCULA.) The very troublesome itching produced by many species of acarus is well known. The louse, the flea, the bug, and the mosquito, are the common enemies of our repose; and in warm climates are far more numerous and fatal. The locusts, which destroy our harvest, the insects so fatal to vegetables of every kind, are scarcely objects of our attention at this time. They must be watched in their state of larvæ, when they may be at once extirpated. The most destructive flies escape our attention by their harmless or pleasing appearance in this state of disguise.

INSERTIO. The union of parts so close that one seems to penetrate the substance of the other, as the insertion of muscles into a bone. It sometimes means the insertion of any instrument into a cavity of the body.

INSE'SSIO, *incessus*, (from *insideo*, to sit upon). Sitting over relaxing vapours.

I'NSIDENS, (from the same,) applied in botany to that which rests upon another part.

INSIDE'NTIA, (from the same). See EPISTAXIS.

INSI'DIANS, (from *insidiar*, to deceive). INSIDIOUS, LATENT; an epithet of diseases which betray no evident symptom, but are ready on any exciting cause to appear; or which, on their first attack, do not show their peculiar or dangerous nature.

INSI'PIDUS, (from *in*, *non*, and *sapidus*, savoury). TASTELESS. See APÆUM.

INSITIO. ENGRAFTING.

INSIPIE'NTIA, (from *in*, *priv.* and *sapientia*, wisdom). Childishness; a low degree of delirium.

INSOLA'TIO, (from *in*, *upon*, and *sol*, the sun). INSOLATION; exposing any thing to the sun. See IETUS SOLARIS, of which this word is a synonym.

INSO'MNIUM. A DREAM. *Quod in somno videtur*. Dreaming is a subject of considerable importance, not only in a physiological view, but as often affording useful prognostics, particularly in fevers; and it has been considered with great attention both by physiologists and metaphysicians; but whether the culture has been erroneous, or the soil stubborn, it is at least certain that the harvest has failed of producing that satisfaction which, from the labour and care, might have been expected. It remains to be determined whether we shall be more successful.

A dream is a series of images either sensible or intellectual, presented to the mind during sleep, more or less vivid, and sometimes so lively as to impress the mind with the fullest conviction of their real existence. They are evidently distinct from the mind, since fear and joy, despair and admiration, are excited by them; since the immaterial principle can decide on the propriety of the actions they may suggest, or can excite volition in consequence of their being presented. The images, however, thus passing before the mental eye are often incongruous, disjointed, and absurd; but whatever forms they may assume, we believe it to be a well established fact, that every part is derived from sensible ideas formerly received. The physiologist who has not particularly attended to this subject may start at so positive an assertion; but after the examination of our own dreams during a series of many years, after the most extensive inquiries, we have never, in a single instance, been able to trace any image, or any

portion of a new combination, which was not previously conveyed to the mind by the senses. So extensive, however, is the power which suggests these sleeping scenes, that their objects are as various as our ideas; and the

*Quicquid agunt homines votum, timor ira voluptas
Gaudia discursus*

form the farrago of this drama of the fancy. Our passions are excited as by reality; our reasoning, however, is weak and imperfect.

In dreams we seem to reason, to argue, to compose; and in all these circumstances, during sleep, we are highly gratified, and think that we excel. If, however, we remember our dreams, our reasoning we find to be weak, our arguments inconclusive, and our compositions trifling or absurd. Some metaphysicians have supposed that from age and reflection our dreams become more consistent and philosophical, and have even supposed that the mind can, during sleep, retain its wonted powers. We are willing to believe that, from age, our minds wander less in this state of repose; but we suspect that it arises from the sleep being less perfect, and not from any experience in the "art of dreaming." We certainly fancy in our dreams that a given image is new; but if we can retain it when awake, we find that this opinion arose from our imperfect recognition, and we shall then be able to recollect its prototype. We seem to think, also, some place, which in fancy is seen in our sleep, to be more beautiful and glorious than any which has before occurred. Yet on awaking we shall find this splendour a thing of shreds and patch work, made up of heterogeneous and disjointed vestiges before offered to the senses.

It has been supposed that the fancy pursues the images of the foregoing day, and that Queen Mab sports "on lovers' lips, who straight on kisses dream." This general opinion we dare not deny, especially when sanctioned by the magic of Shakspeare's poetry. Yet our experience does not support it; and when the mind has been exhausted by joy or sorrow, we have often found the sleep sound and refreshing. When less exhausted, the fancy seems to play with various images, not always connected with the previous state of mind. We have even thought that when the mind has been very deeply impressed with any peculiar images, that such have less seldom occurred in dreams than their opposites. That dreams ever offer any foreboding of future ills or benefits; that we ever, in this state, receive information from preternatural sources; are opinions which we leave to the childishness of the nursery, or the wandering fancies of superstition and dotage.

The *ægrî somnia* have been proverbial, as descriptive of disjointed incongruous images; and what may be considered as the pathology of dreams, will perhaps more fully illustrate their nature. In fevers the dreams are often highly distressing; from indigestion they are equally so, but of a different kind. In the former, the mind is hurried from one object to another with inconceivable rapidity; in the latter, chained down and oppressed with a heavy weight. Should it happen that the patient is relieved of his load during his dream, the complexion of these airy nothings immediately varies. Aversion is changed to liking, disgust to complacency, oppression to freedom. If the

heat of fever is relieved by a salutary perspiration, the patient is no longer hurried through the trackless air, but reposes in a verdant meadow, or more often drinks of the cool stream, for the thirst vanishes. In general, very deep sleep is oppressive; light sleep salutary and refreshing. The senses no longer convey the usual impressions, but images are excited, which, though not wholly similar to the usual ones, are not very different. Thus violent heat will suggest a dream of scorching fire; throwing off the clothes in winter, of walking through a river. The effects of opium on our dreams are singular. In those with whom it agrees it excites the most pleasant images; when it disagrees, the most frightful: in all it greatly influences the ideas of the duration of time. A man of genius and an artist under the influence of opium, fancied Holbein's Dance of Death realized, and that each figure assumed a real form, and was presented to him in all its horrors. He suffered, in his opinion, from this exhibition, for many hours; and, at last, awaking in terror, heard the clock strike twelve, when he recollected that he did not sleep till after eleven. The author of this article, in whom opium excites the most agreeable images, has experienced the same change in his ideas of time. We have sometimes thought the nature of dreams influenced, in a certain degree, by the temper and disposition of the dreamer. Thus the sanguine cheerful temper finds, in all his distresses, a means of escape; where the more gloomy melancholic disposition perceives no resource till he awakes in horror. But in this *we* may be styled dreamers. The other facts recorded in this article have been verified by repeated observation.

The cause of dreams has excited various speculations. This waking sleep, or sleeping activity, appeared to Baxter so inconsistent, that he supposed immaterial spirits were amused, or engaged in suggesting these plays of fancy, and sometimes, perhaps, conveying important information. We cannot deny the existence or employment of these spiritual agents; but can scarcely conceive, in the whole circle of creation, beings so useless. They are, however, wholly unnecessary; for, in the pathology of dreaming, we have seen that the cause is purely corporeal; and, indeed, Baxter's opinion is, we believe, consigned to the same oblivion with that which looks to dreams as foretelling future events.

Wolfius supposed a previous excitement of some part necessary to suggest to the fancies during sleep; and, in fact, delivers the fictions of Shakspeare in the garb of sober sound philosophy. This opinion is, however, inconsistent with the phenomena of dreaming; and we have no modern idea on this subject which need detain us, except the opinion we are about to explain, originally derived from Dr. Cullen.

In sleep, Dr. Cullen observes, that there is a partial collapse of the brain, at least so far as respects the animal functions; and this partial diminution of excitement is shown by the delirium which occurs in the interval between the sleeping and waking state. To different degrees of the collapse, dreams, more or less vivid, appear to be owing. Dreams, indeed, are of the nature of delirium. Similar heterogeneous or disjointed ideas constitute both; and the whole must be resolved into that unequal balance of the nervous power in the brain arising from diminished energy. The proof of this is the want of the usual associations; another, the

deficiency of judgment; a function, when perfect, which arises, as we have seen, from a free communication between the different parts of that organ. The defect of judgment is seen from a high opinion we form of what we suppose we have written or said in our dreams, which is often ridiculous, and strangely heterogeneous.

Yet, it may be asked, are no ideas suggested in our dreams which deserve the attention of our awakened judgment? We have heard of some such suggestions, and suspected that we have experienced them; but they consist only of a happy recollection, or a new combination, which we are sufficiently awake to be pleased with, and rouse ourselves to recollect. We remember dreaming of being asked for a motto for an air balloon, and immediately suggested the following:

*Tentanda via est qua me quoque fossum
Tollere humo victorque virum volitare per ora.*

Every instance of peculiar genius or supernatural information in dreams may be referred to one of the sources just mentioned.

Though this partial collapse explains, in some degree, the heterogeneous combinations of dreams, it does not show us how the images are excited. It will be at once obvious that this question includes one to which no answer can probably be given, viz. in what manner do sensible impressions act on the mind to produce ideas, or how, in turn, does the mind act on the brain, by means of volition, to excite action? We may hazard a few speculative remarks, which, if ill founded, will detain the reader but a short time. We have seen that the power which resides in the brain and nerves is probably a subtile fluid, capable of vibrations, and that its action consists in these vibrations. If, then, such have been excited by sensible impressions, we know that they may be renewed by powers more inconsiderable; and it is not impossible even that the motion of the blood, in those parts of the brain where the mobility of the fluid is considerable, may excite vibrations, and these be attended with the same ideas which originally followed them. In constitutions where the nervous fluid is particularly mobile, or in cases where the circulation is hurried, dreams will be more frequent, more vivid, and often more troublesome.

Dreams, we have said, are useful in affording prognostics in various diseases. When the dreams are hurried and violent, we have often reason to expect delirium: when the mind in fevers is gloomy and distressed, and the dreams frightful, the fever soon becomes dangerous; but when in sleep, the fancy is soothed by pleasing images, the disease is seldom alarming. In these cases, the consequences are probably those of terror on one side, and complacency on the other; and the peculiar states of fever may not be the causes of the dreams. Yet, when we recollect that, in other instances, diseases of the body excite dreams of distress and horror, we must think that the more violent corporeal affections are really the causes of the terrific visions. In either case they are often useful prognostics.

If any part of the brain is more easily excited to action by having been previously impressed, the mind, on the contrary, becomes more insensible. Thus, the person used to distress is comparatively calm in witnessing the most painful scenes: the mind, once

harrowed with horror, will bear common trouble without emotion. This will account for the fancy not always pursuing, in sleep, the painful scenes of the day, or rather for their not being followed by pungent distress, so that they escape the recollection when we are awake.

Is it a fact that the dreams of children are more terrific than those of adults? Infants certainly dream, and seldom awake in terror; in fact they know not the tendency of objects, and are not capable of appreciating their effects so as to be terrified. When they are farther advanced, the tales of the nursery often inspire horrible images, which may again return in their dreams; or their systems, more mobile and irritable than those of adults, may be more susceptible of violent impressions. We could wish, however, that the fact were more decidedly ascertained.

Animals dream, particularly dogs; but in these visions they are more often pleased than terrified, though sometimes angry. Their bark is different, and the voice of those who talk in their sleep is usually altered. We have no evidence of the feathered race being subject to these nocturnal visitors; and perhaps they are connected, like associations of ideas, with the proportional bulk of the brain.

See Baxter on the Immateriality of the Soul; Lord Monbodo's Works; Hartley on Man; Wolfius's Ontology; Cullen's Physiology; and Lommius.

INSPIRA'TIO, (from *in*, and *spiro*, to breathe). INSPIRATION; *eispnoe*, *epipnamos*. The action of the chest and diaphragm, by which the air is drawn into the lungs. See RESPIRATIO.

INSTILLA'TIO, (from *instillo*, to drop upon,) often synonymous with embrocatio.

INSTITA, (from *incisto*, to stay). A FILLET; and a TENIA.

INSUFFLA'TIO, (from *insufflo*, to blow into). Blowing into any cavity, to convey any remedy to a part affected.

INSULTUS, (from *insulto*, to attack). The first invasion or access of a paroxysm.

INTEGA'STRUM. The decussation of the optic nerves. Paracelsus.

INTEGUME'NTA, (from *intego*, to cover). INTEGUMENTS; the cuticle, rete mucosum, cutis, and membrana cellularis; sometimes applied to particular investing membranes, as the coats of the eye.

INTEMPERA'NTIA, (from *in*, *non*, and *tempero*, to moderate). INTEMPERANCE. Besides its usual signification, it sometimes is synonymous with dyscinesia.

INTEMPE'RIES, (from *in*, *non*, and *tempero*, to mingle.) See DYSINESIA.

INTE'NTIO, (from *intendo*, to stretch out). INTENTION. It is either extension or indication. Healing a wound "by the first intention," means when divided parts are placed in contact, and unite without any suppuration.

INTERCE'PTIO, (from *intercipio*, to stop). See APOLEPSIS.

INTERCOSTA'LIS, (from *inter*, between, and *costa*, the ribs,) any part situated between the ribs; viz.

INTERCOSTA'LES ANTE'RIAE, which arise in pairs from the aorta, and run on the lower parts of each rib. They are eight, nine, or ten in number, of which the upper come from the subclavian. The

intercostales of the true ribs anastomose with the internal mammary; those of the superior go to the muscles of the belly.

INTERCOSTA'LES MU'SCULI; *mesopleurici*; INTERCOSTAL MUSCLES are eleven in number on each side externally, and as many internally; in all forty-four. The external ones pass downwards and forwards; rising from the edge of the superior, and inserted into that of the inferior, rib: their fibres run nearly parallel; but near the sternum disappear. Their use is to elevate the ribs. The internal ones are the reverse of the external; rising from the edges of the inferior, and inserted into those of the superior, ribs; consequently they decussate each other. These depress the ribs; so that, by the alternate action of the two sets of muscles, the thorax is expanded in inspiration, and diminished in capacity during expiration.

The levatores costarum longiores and breviores of Albinus are those portions of the external intercostals which arise from the the transverse processes of the vertebræ, where the ribs are fixed to them, and other portions which pass over one rib and terminate in the next below it. Similar portions of the internal are called by Douglass *costarum depressores proprii Cowperi*.

INTERCOSTA'LES NE'RVI; INTERCOSTAL NERVES, *sympathetici nervi majores*, are formed of all the spinal nerves, and of branches from the fifth and sixth pairs from the brain. They run on the other side of the ribs. This is a very important part of the nervous system; but it has already claimed a large share of our attention. See CEREBRUM.

INTERCOSTA'LES VE'NÆ, DEXTRÆ, SUPERIORES, ET INFERIORES. See AZYGOS.

INTERCU'RRENS FE'BRIS, (from *inter*, between, and *curro*, to pass). AN INTERCURRENT FEVER. Some fevers are epidemical in certain seasons only; others happen in all years, and are only occasionally epidemical. The former are called *stationary*; the latter, by Sydenham, *intercurrents*. See Sydenham's Works.

INTERCU'RRENS VEL INTERCI'DENS PULSUS. When between two strokes at proper distances a third quickly intervenes.

I'NTERCUS, (from *inter*, between, and *cutem*, the skin). See ANASARCA.

INTERDE'NTIUM, (from *inter*, between, and *dentes*, teeth). The intervals between teeth of the same order.

INTERDI'GITUM, (from *inter*, between, and *digitus*, toe or finger). A CORN BETWEEN THE TOES.

INTERFEMI'NEUM, (from *inter*, between, and *femur*, the thigh). See PERINÆUM.

INTERFOLIA'CEUS, (from *inter*, between, and *folium*, a leaf). Proceeding from between opposite leaves.

INTERLU'NIUS MO'RBUS, (from *inter*, between, and *luna*, the moon; because it was supposed to affect chiefly those born in the wane of the moon). See EPILEPSIA.

INTERMISSIO, (from *intermitto*, to discontinue). The intervals betwixt two fits of any distemper.

INTERMI'TTENS FE'BRIS, (from the same). AN INTERMITTENT FEVER, is a febrile disease consisting of distinct attacks, with perfect freedom from fever in the intervals. Different names are given to this fever according to the periods of its return; if after twenty-four hours, a *quotidian*; if after forty-eight hours, a

tertian; if after seventy-two hours, a *quartan*; after ninety-six hours, a *quintan*, or a *semitæus*. Such intermittents are, however, rare; and those with longer intervals have been styled *erratic*. Those are called *autumnal* which begin in August, and those *vernal* which begin in February.

Dr. Cullen places intermittent in the class *pyrexia*, order *febres*; defining it fever arising from marsh miasma, consisting of many paroxysms; a total freedom from fever, at least an evident remission; returning with a marked exacerbation, and generally with shivering; having one paroxysm only in a day. He adds, "whoever will weigh what will be delivered concerning remittent fevers, and their distinction from continued fevers, strictly so called, will readily see why I have thought it necessary to change the character formerly given of intermittents as well as continued fevers." The latter he defines fevers having no intermission, nor arising from marsh miasma, but continuing only with slight remissions and exacerbations; having two exacerbations each day. "He thinks that the nosologists, Sauvages, Linnæus, and Sagar, have not acted judiciously in instituting a separate order of remittents, as if they were altogether different from perfect intermittents; for those fevers called *remittents* arise from the same cause, viz. marsh miasma, as intermittents; each appears as an epidemic, in the same place, and at the same time of the year; each is cured exactly by the same remedies; and very often in the same subject, the same disease sometimes exhibits the intermittent, sometimes the remittent, type; diseases, therefore, so extremely alike with respect to their causes, mode of cure, and type, ought neither to be placed under a different order, or in different section."

The patient, though free from fever, is slightly indisposed the following day with chilliness and languor: he hath a weak and slow pulse, his urine is pale, and either deposits a sediment, or contains a small cloud suspended in it; the sediment is of a reddish colour, exactly resembling brick dust; the surface frothy, or covered with a pellicle. The beginning of autumnal intermittents is sometimes not very different from that of continual fevers. When weakly persons are the subjects, the intermissions are proportionally less distinct.

Obstinate intermittents often end in dropsies, or hectic from obstructed viscera. Vernal intermittents often require no assistance, and very rarely prove fatal.

Intermittents are distinguished by the very regular appearance of each stage of fever formerly described (see FEBRIS); and the continuation of the paroxysm sometimes extends to twenty-two hours, the patient having scarcely two hours interval; but this chiefly happens when two diseases of this kind have attacked the patient at once, so that the fit of one comes closely on the conclusion of the former paroxysm. A single quotidian will, however, sometimes last eighteen or twenty hours.

In general it will be found that the longest paroxysms have the shortest intermissions; and the contrary; but the time of the paroxysms is occasionally anticipated or retarded. An increase of the interval, or rather a retarded paroxysm, shows the disease to be declining; while an anticipated attack is rather a sign that the disease is becoming a remittent or continued fever.

It is singular that intermittents rarely attack in the

night. When the paroxysm anticipates, so as to come before eight, its next step is usually to the febrile period of the evening, previous to the usual day of its attack; and when it is retarded beyond eight or ten in the evening, the following attack is usually at eight in the morning following its accustomed day. Continued fevers are said to attack in the night, but we have generally found that the patient has complained in the evening, and that the fever has then formed, though the rigor has only taken place during the night, or rather about four in the morning.

The attack of intermittents is sometimes attended with the most alarming symptoms, such as syncope, apoplexy, a great load on the chest, with threatening suffocation, epileptic paroxysms or violent spasms, or a coldness, which increases till the patient sinks into torpor, soon followed by death. These are circumstances of peculiar danger, and require the most minute attention. The hot fit is also sometimes so violent as to be attended with delirium, and occasionally with rupture of the vessels, from the violence, in the language of Dr. Cullen, of the reaction. These circumstances require particular attention in the conduct of the cure.

Intermittents are sometimes complicated; that is, there may be two tertians, or two quartans, existing at the same time. The double tertian of authors, the *duplicana* of Linnæus, consists of two tertians, returning each at their regular times, and thus attacking every day. The real disease is distinguished from a quotidian by the time of the attack, which in a tertian is about noon, by the shorter paroxysms; and by the fits of fever which occur on the alternate days resembling each other: while, if that on the succeeding is compared with the fit of the former day, some difference is observable. Another form of the double tertian is with two paroxysms in one day; and this kind is distinguished by the appellation of *tertiana duplicata*. A triple tertian has also been observed, consisting of two paroxysms on each alternate day, and one only in the interval. This is the *semitertiana* of authors, the *tertiana triplex* of Sauvages. Tertians differ also in the degree of remission, when complicated in the manner already mentioned. Thus a double tertian, which returns daily, will have often the remission between the unequal and equal day; between the third and the fourth, for instance, more strongly marked; between the equal and unequal day less strongly.

Quartans vary as much; but, indeed, in this country quartans are uncommon, except in the marshy countries on the east of this island. The *quartana duplicata* of Sauvages consists of two paroxysms every fourth day, and on the other days none. The *quartana triplicata* consists of three paroxysms every fourth day, with three days of intermission. The *quartana duplex* has only an intermission of the third day, and the paroxysms of every fourth day are alike. The triple quartan attacks every day; and the paroxysms of every fourth day resemble each other. This disease, like the double tertian, is distinguished by the period of the attack and the shortness of the paroxysms. The author of this article, in thirty-five years practice, has seen but one quartan, which was imported from a distant county.

Quotidians vary but little, except in their causes and their partial attacks. Many of these are symptomatic only; but the partial quotidians attended with violent

pains are peculiarly distressing, and with great difficulty removed. The *quintana* and *septimana* are described by authors very vaguely, and seem, in general, to be symptomatic.

Intermittents are not always dangerous, and the vernal agues generally disappear on the approach of summer. The autumnal ones are more frequently attended with infarctions of the liver, and the more obstinate kinds of these, the quartans, leave often this organ in a scirrhus state. Dropsies and hectic are the consequence. It has been, on the other hand, contended; that vernal tertians are salutary, and clear the constitution of other diseases, as indigestion, flatulency, and acidity of the stomach; habitual rheumatism and other inflammations; cutaneous and nervous complaints. For this opinion we offer the very respectable authority of Dr. G. Fordyce, for having seen but few cases of intermittents, we will not add, as an objection, that such salutary effects have not occurred to us. We have found every intermittent, which we have seen, to be a disease which we have been anxious to cure as speedily as was consistent with the safety of the patient.

The cause of intermittents is exclusively the miasma from marshes, and the remote causes those of fever in general. We have already observed, that no satisfactory reason has been assigned for the recurrence of the paroxysm. Dr. Cullen attributes the duration of fevers to the violence of the spasm or the weakness of the reaction; and though in each paroxysm of intermittent the spasm may be conquered, yet its cause, the atony, remains to be combated by a new series of symptoms. It is evident that in intermittents the cause remains, for they leave a languor, in part the effect of the exertions; but, in part also, of the remaining debility. While we have modified, in some measure, the doctrine of Dr. Cullen, yet this explanation, with a change of the language, may appear probable; and it is supported by a fact already stated, that the concluding paroxysm is the most violent. We know not, however, the duration of an intermittent in consequence of the debility remaining unsubdued; for we shall find, that it is often continued from habit, and that raising any violent emotion, fixing the attention, or exciting a different train of motions, in any way, will prevent its recurrence; and, when once prevented, the fit seldom returns. It may be then questioned, whether, even in the early stages, it may not be the creature of habit. When an intermittent first attacks, its paroxysms are seldom regular. When they become so, they soon establish a habit which we know is with difficulty removed; but this habit seldom takes place but in weak, mobile constitutions.

In the cure of intermittents, our first object is to prevent the recurrence of the fit; our second to conduct the paroxysm, so as to obtain a complete solution of the disease; the third to increase the general tone of the system, in the intervals, that the disease shall not again return.

Our first object, for it is not strictly an indication, is limited to those remedies whose immediate action may prevent the attack. These are means of increasing the tone of the system, or supporting the action of the extreme vessels, so as to prevent their quiescence, perhaps their spasm. The tone of the system is increased by stimulants and tonics. With this view aromatics,

the strongest acids, and ardent spirits, in almost every imaginable variety of form, are administered when the fit is expected. Very large doses of bark are also given, so as to accumulate from one ounce to two in the stomach, at the time of the usual return. The former of these plans is highly injurious when a phlogistic diathesis prevails in the system; for it converts the intermittent often into a continued fever, with topical inflammation. The latter is equally injurious, when the stomach and bowels have not been previously cleared; and occasions those infarctions styled *ague cakes*, which have been so often attributed to the bark. In different circumstances each has succeeded.

The action of the extreme vessels is supported by emetics and sudorifics. An emetic is given previous to the return, while the perspiration is supported by warm negus, the volatile alkali, or the sudorific powder of Dover. Opium, with warm teas, will equally succeed; but, in general, for the reasons formerly assigned, great external heat should be avoided. Opium is not the only medicine which acts peculiarly on the vessels of the skin, though it is the most powerful. Guaiacum has a similar effect; and the ammoniated tincture, when joined with opium, is often a valuable remedy used with these views. Musk, empyreumatic oil, and ether, are said to have had a similar effect, without producing sweating; but in such cases, they probably, if successful, which has been doubted, act as simple stimuli. To the same source may be attributed the effects of bracelets of mustard seed and garlic to the wrists and ancles; bruised spiders and tobacco, applied to the wrists; yarrow, &c. to the feet. These excite so great a degree of inflammation as to increase the heat as well as the circulation, and have often undoubtedly succeeded. We must add, that whenever we attempt to prevent the paroxysm of an intermittent by sweating, this mode of relief must be continued till the period of the paroxysm is at an end, or at least till the time when the sweating stage would have otherwise commenced.

Those means which excite terror, surprise, and horror, or, as we have said, raise a train of new emotions, will prevent the return of paroxysms. A man has been pushed into the water; fire has been cried; the most distressing tidings invented and communicated. A patient, labouring under an ague, has been ordered to swallow half a pint of his own urine; to hold a toad in his hand till it dies; to eat common spiders in a raisin, or cobwebs in crumb of bread. All these remedies fill the mind with such dread as to counteract the impression of the cause; but in general they are dangerous, and when we wish to prevent the fit, we depend rather on the tonics, the stimulants, and the sudorifics. These are often highly necessary; for when the fever attacks with apoplexy, epilepsy, or other symptoms which threaten the life; or when the patient is so far debilitated that another fit would be probably fatal; we must take the most decisive steps to prevent it. We remember to have seen three cases of this kind, in which by the sudorific plan, detailed above, we succeeded.

To conduct the paroxysm so that its solution shall finally remove the disease, is often beyond our power. An emetic, given at the first approach of coldness, will often lessen both it and the next stage; and we must repeat, what Dr. Fordyce tells us, that he has remarked

the superior efficacy of the antimonial preparations to the ipecacuanha. When the hot fit comes on it must be mitigated by cold, and by the cooling diaphoretics. Opium, at this period, is said by Dr. Lind to lessen the heat, and hasten the sweat; and when the last stage has fully come on, the exhibition of the bark is said to render the sweating more effectual. Such are the observations of authors, which we can neither confute nor confirm. From what we have, however, read and seen, we suspect that these measures lessen the inconveniences of the paroxysm, but seldom put a stop to the disease.

In the intervals our chief exertions must take place; and we have been lately accustomed to trust almost exclusively to the Peruvian bark. We have seen (see *Cortex Peruvianus*) that we can derive little information from the sensible qualities of this medicine, or from its analysis, either in the milder or more forcible separation of its component parts, and we must rest contented with the fact, that the bark will usually cure intermittents. We say "usually," for was it so certain a remedy as the language of authors would lead us to suppose, they would not fly from the common to the red and yellow kinds, to combinations of bitters and aromatics, to copper and to arsenic. As it is, however, the common remedy, we must direct its exhibition.

We have already spoken of the bark, given immediately preceding the fit, and in the sweating stage. We now speak of it as a remedy in the intervals. In general, then, it must not be given while there are any considerable infarctions of the viscera. We have already shown (see *Febris*), that fever almost consists in, or is constantly attended with, a disturbed balance of the circulation, and that the biliary system and the brain, from their structure and constitution, receive a large proportion of blood, which is confined to the larger vessels. Fever cannot, therefore, continue long without infarctions of the liver at least, if not excessive fulness of the cerebral system; and in this state the bark is certainly injurious. Physicians may colour this objection in a variety of ways, but they cannot elude it. Intermittents then, which continue usually some time without decisively showing their true nature, must be attended with at least fulness in each viscus, and this should be previously removed. We have already shown that emetics and cathartics are the chief remedies for this purpose; and hinted, that it was not without reason that physicians formerly condemned the cortex as the cause of these swellings; but, in reality, they should have blamed its injudicious use. These opinions are confirmed by another caution, universally laid down, that the bark is only admissible during a remission. In fact, at the time of the fit the fulness is most considerable: after its solution, that degree of fulness only remains which is owing to the dilatation of the vessels. Dr. Fordyce is so confident of its injury during the paroxysm, that he directs it to be omitted during the time that the paroxysm would have come on. In other words, if the fit is expected on a given day, which usually lasted from ten to four, or six, and if the bark, taken previously, has prevented the accession, the remedy must still be omitted during this period, though no accession really takes place. We find also that, in remittents, unless the remission is considerable, the bark is not always admissible; in continued fevers it is very rarely so.

Though the bark be confined to the interval, it is not necessary that it should be exhibited with equal freedom in every period of that interval. In a quartan, for instance, though given in the first day of intermission, its doses need not, during that day, be considerable, or often repeated. On the next, the medicine should be given in as large doses as the stomach will bear. In a tertian, the dose of the remedy should be greatly increased during the last six hours of the interval. What the dose should be must be determined by the judgment of the practitioner, and the constitution of his patient. Not less than an ounce of the powder will effectually stop a tertian; and a much larger quantity must be taken in the interval of a quartan. As the interval of the fits of a quotidian is short, we must be more active; but the disease should be lessened by emetics and cathartics before the bark is employed.

It is common and highly proper to recommend the removal of a diathesis phlogistica previous to the exhibition of the bark; but it is equally necessary to guard against its purging or its constipating effects. The former is most successfully opposed by combining a laxative, as rhubarb with the bark, and the latter by opium; but as the rhubarb adds to the bulk, and to the nauseous taste of a medicine, already sufficiently disagreeable, we may choose the period of the accession for the action of any quick purgative, as the castor oil with senna; the senna or jalap with cream of tartar, or the jalap with calomel. Should opium disagree, the bark may be taken in a strong decoction of logwood. When we have been most successful, we should not too soon abandon our remedy, as intermittents, except when continued from habit, are very liable to a relapse.

The bark, with every precaution, will not sometimes remain on the stomach, though joined with aromatics, with opium, or followed by an effervescing draught. In this case, we have been directed to quilt it in a calico waistcoat, to be worn next the skin; to bind it round the wrists; to inject it in a clyster; or to bathe the patient in its decoction. Each method is said to succeed; but what will not appear to succeed in the eye of its inventor? If the bark is really useful in these ways, we should expect that it will not be employed in any other; but when we reflect on the quantity required to cure an intermittent in the stomach, an organ which so quickly sympathises with the extreme vessels, the brain, and the sensorial power, we can scarcely expect lesser quantities, applied less advantageously, to succeed. The advocates of this practice have quoted Dr. Alexander's experiments with some triumph, to show that bark applied to the skin is absorbed; but when large quantities have been given to check an intermittent at once, and vomiting has succeeded, the whole is apparently evacuated though the fit be stopped. If it be contended that the bark in this way is really applied to the extreme vessels themselves, the advocates for the practice must show how it passes the cuticle, except by the absorbents; and prove, what may be still more difficult, how in this way it can obviate the cause, viz. the atony of the sensorial power.

The prejudices against the bark, on its first introduction, led to a variety of substitutes for it in these diseases; and all the bitters and astringents were occasionally employed, joined sometimes with alkaline and neutral salts, at others with aromatics, more simple

stimulants, or antispasmodics; the abrotanum, the various species of wormwood, the carduus, the centaury, the camomile flowers, the columbo root, orange and lemon peel, gentian, quassia, tansy, ruc, St. Ignatius' bean, with almost every medicine which contains a bitter juice. It is a doubt whether the bitter is the same in all. When the bitters are pure, as in the gentian and camomile flowers, the principle is apparently the same; but the wormwood, for instance, contains an essential oil totally different from its bitter juice; the orange peel not only an essential oil, but an astringent principle. This may have perhaps occasioned the preference of the latter, since the bark also contains an astringent portion; and whatever aversion physicians had to the bark, in their substitutes they came as near it as possible. The action of bitters and astringents we have already noticed. See AMARA and ASTRINGENTIA.

The astringents employed have been the alum, the galls, the tormentil, and the oak bark: each, it is said, has been successful; but their success has not been so decided as to lead to their general employment instead of bark.

The additions to the bitters and astringents, though chiefly to the former, have been, we have said, alkalis, neutral salts, stimulants, or antispasmodics. Boerhaave was fond of the bitters with alkalis as producing a saponaceous medicine, in his opinion a powerful deobstruent; though he sometimes preferred the neutrals. These are undoubtedly of great utility as antifebrile medicines, though seldom sufficiently powerful to stop the paroxysms of an intermittent. The aromatics usually added are nutmeg and ginger; the antispasmodics, the animal oil of Dippel, or, sometimes, the less elegant form of candle snuffings. The latter, with nutmeg, is said to have often effected a cure. Similar additions sometimes render the bark more effectual.

The other substitutes have been the metallic tonics, copper, arsenic, and iron. We know not that copper has been employed in the pure intermittents, though used with success in the intermittentes larvatae, which we shall notice in the following article. Arsenic was employed many years since in this disease, and lately has been in general use, from the success of Edwards's ague tincture (see ARSENICUM). It is undoubtedly a very active and powerful medicine; nor have we found any disadvantages from its use. It has succeeded, when the bark in every form, and with every addition, has failed. Fowler's arsenical solution is made in the following manner: take arsenic very finely powdered, and fixed alkaline salt, of each sixty-four grains (some ordered half the quantity); distilled water, half a pint; these are to be put into a Florence flask, and placed in a sand heat: the water is then to boil slowly till the arsenic is perfectly dissolved: when the solution is cold, half an ounce of compound tincture of lavender is to be added, and of distilled water, another half pint, more or less, so that the whole of the solution shall yield by measure a pint, or rather weigh fifteen ounces and a half. Patients from two to four years of age may take from two to four drops; from five to seven years, from five to seven drops; from eight to twelve years, from seven to ten drops; from thirteen to eighteen and upwards, twelve drops at a dose, in any proper vehicle, two or three times a day.

Iron is sometimes added to the bark and bitters to increase their virtue; but it has, we believe, been

seldom trusted alone. All these medicines seem to act by increasing the general tone of the system, and thus counteracting the debility in which the disease apparently consists. The mineral acids, though powerful tonics, have not been used, we believe, in this disease.

The general management of patients, who labour under intermittents will not detain us long. It is in the first place necessary to remove them from the infected air; but the activity of modern husbandry has lessened the number of marshes, and the disease is comparatively rare. In parishes where the number of intermittents was not annually less than two hundred respectively, the disease is not found, or only in a few instances in its disguised state. The diet should be light, easy, and digestible. The ancients seldom admitted of food in the first days of fever; and in the early periods of intermittents, when the disease has seldom any regular interval, the less nourishment that is taken, the sooner will the fever assume its proper type. In general, when the fits are more distinct, animal food should be avoided unless there is sufficient time to complete the digestive process before the expected return. This precaution must be continued after the fits have disappeared.

The *intermittentes comitatae* and *perniciosa* of Torti are more nearly allied to the remittents, and are indeed often of the remittent kind. They will therefore be considered with advantage under that article. See REMITTENTES.

See Torti Therapeutice Specialis, Sydenham's Works; Cleghorn on the Diseases of Minorca; Hunter on the Diseases of the Army; Senac de Recondita Februm Natura; Fordyce on Fevers, second Dissertation.

INTERMITTENTES LARVATÆ. A fever of a truly intermittent nature is often disguised under the appearance of a very different complaint, or seems to the inexperienced practitioner a fever of a different kind. In the first, the real disease may generally be suspected from the appearance of regular paroxysms, or more certainly by perfect intermissions, since these more often occur in such disguised intermittents than a regular recurrence of the disease. *Intermitting pains* of every kind, where the paroxysm is completely terminated, are of this kind; and the most common and most troublesome instance is the *hæmierania*. The distinction of the complaint is not easy, for pains in the head, from whatever cause, are not constant: even the DOLOR FACIEI CRUCIANS, q. v. the tic douloureux, has its remissions (see CEPHALALGIA). *Hæmierania*, therefore, is distinguished from its situation, occupying often with such minute precision one half of the head, that the patient can place the point of a pin between the part pained and that unaffected; frequently from its regular attack, at least a regular continuance; in many instances from its being ushered in by rigor, followed by feverish heat; almost always from soreness in the bones of the cheek of the side affected during the paroxysm only. It is a disease of the most distressing kind, for its obstinacy is equalled only by the violent degree of the pain.

The intermitting nature of this complaint is known from its occurring in the low, damp, marshy situations, from its regular recurrence, and from the remedies which relieve it. But among these we cannot reckon

the Peruvian bark alone; for, though large doses have sometimes appeared to cure, they are often ineffectual, so that we are rather inclined to attribute the relief, sometimes experienced, to the spontaneous cessation of the disease. The remedy which most frequently succeeds is that recommended by Dr. Grant, consisting of an ounce of valerian, half an ounce of bark, two drachms of the Philonium Londinense, one drachm of kali, with a scruple of rhubarb, made into an electuary with simple syrup. He remarks, what we have found to be true, that if this quantity is swallowed between two paroxysms, the last will be greatly mitigated; and if the same quantity is swallowed between the two next, the complaint will be so far cured as to be scarcely troublesome. The effects of this plan, however, are rendered more certain by giving an emetic before the expected attack, with a blister behind the ear of the side affected; and as it is necessary to keep the bowels free, which the proportion of rhubarb is unequal to, the period of the accession may be employed for this purpose. The duration of the pain is amply sufficient for the operation of salts, of the oleum ricini, or jalap.

The quantity to be taken, according to this plan, may be sometimes inconvenient; but the pain is so excruciating that we have scarcely found any one whose resolution has not been equal to the alternative. It sometimes, however, though rarely, has happened, that the stomach will not retain it: the resolution has occasionally failed; and even the medicine has not succeeded, for the disease in our practice has been frequent. In such circumstances the copper has sometimes relieved; and, in more than one instance, a secret medicine, which is pretty certainly a solution of arsenic. If the period of the fever is not required for the action of a laxative, the pain may be mitigated by opium, with which camphor or musk has been combined; but of these additions we cannot speak from our own experience.

Other periodical pains and nervous complaints, as the whooping cough, hiccough, nausea, colic, and palpitations, regularly recurring, are very frequently removed by the same means (Senac). It has been usual to give the bark in every periodical complaint; but it seldom succeeds, except in doses much more inconvenient than those of Dr. Grant's medicine; and, when it seems to relieve, it leaves the patient more subject to relapse.

There are, however, symptoms periodically recurring, not always of this kind; but we have only been able to trace them when belonging to one disease, viz. lues venerea. We have seen a periodic ophthalmia, a hæmierania, and an hæmorrhage from the nose, recurring at regular intervals in this disease. Each has been cured by a mercurial course. It may be said, that mercury, like copper and arsenic, will remove it; and it may be true, but each laboured under syphilis. The patients are at this moment alive, and the author, by a personal application, has refreshed his memory on the different subjects. We must add, however, that Senac, an author of the highest credit, mentions intermitting hæmorrhages, ophthalmia, ear and toothach, cephalalgia, pains under the scapula, nephritic affections, pain of either leg or arm, and of the stomach, often without any other appearance of fever. Those intermittents also which we have mentioned as attacking with syncope, apoplexy, asthma, and convulsions may

be properly styled *larvata*. The nature of these cannot be at once known; but some opinion may be formed from the prevailing epidemic, from the damp marshy situation in which the patient lives, from the bilious vomiting, the lateritious sediment in the urine, from the recurrence; but, above all, as we have said, from the very perfect intermission. The third paroxysm is popularly supposed to be fatal; indeed it often is so.

The varieties of intermittents which we have noticed, in which the cold obstinately continues; where the hot fit becomes phrenitis, or where the subsequent debility is attended with marks of putrefaction, and the worst symptoms of malignant fevers, have been reckoned among the disguised intermittents by Morton and Torti. But these authors were preceded in this opinion by Salius Diversus, by Valesius, Mercatus, &c. Indeed were a descriptive (*raisonné*) Medical Biography, a work much wanted, ever published, numerous reputed discoveries might be carried far beyond the ages of the supposed authors.

We have already mentioned the manner in which intermittents pass into remittents, and into continued fevers of the worst kind; but we have referred the consideration of these subjects to the REMITTENTS, q. v. which afford examples of the most destructive exacerbating fevers. See Morton de Febribus, Senac de Recrudita Februm Natura, lib. 2.

INTERNO'DIUM, (from *inter*, between, and *nodus*, a joint,) that part of the stalks of plants which are between two joints or knots; in anatomy the knuckles, and the space between the joints of each finger.

INTERNU'NCII DI'ES, (from *internuncio*, to go between; as standing between the increase and decrease of the disease). See CRITICI DI'ES.

INTERO'SSEA ARTE'RIA, (from *inter*, between, and *osa*, bones). The CUBICAL ARTERY, in its course between the heads of the radius and ulna near the interosseous ligament, gives off these arteries, the internal and external.

The internal runs close to the ligament, till it reaches below the pronator teres, where it perforates the ligament, and passes to the convex side of the carpus, and back to the hand, where it communicates with the external interosseus, the radial and the cubical arteries.

The external pierces the ligament about three fingers' breadth below the articulation, and sends off a branch towards the external condyle of the os humeri, under the ulnaris externus and anconæus minimus, to which, and to the supinator brevis, it is distributed. The interosseous artery then runs downwards on the outside of the ligament, giving branches to the ulnaris, externus, extensor digitorum communis, the extensores pollicis indicis, and minimi digiti. Having reached the lower extremity of the ulna, it unites with a branch of the internal interosseous artery, which at this place runs from within outwards, and is distributed with it on the convex side of the carpus and back of the hand, communicating with the radial artery and with a branch of the cubital. By these communications this artery forms an irregular arch, from whence branches are sent to the external interosseous muscles, and to the external lateral parts of the fingers.

INTERO'SSEA LIGAME'NTA. The interosseous ligaments in the fore-arm are fixed by one edge along the sharp angle of each ulna, and by the other along that of

the radius. They principally consist of two very strong planes of fibres, which cross each other at oblique angles, and leave holes at different distances for the passages of blood vessels. The ligament ties the two bones closely together, and the two planes serve for the insertion of several muscles. In the supination of the hand it is very tight, but in the pronation it is folded a little lengthways.

INTERO'SSEI MU'SCULI, are found both in the hands and feet. There are three in the upper part of the hand, and as many on the inferior. Their name describes their origin, and they are blended with the lumbricales, performing the same office, of moving the fingers sideways. The first of the interossei interni is called by Albinus *posterior indicis*; the second and third are the *prior annularis*, and *interosseus auricularis*. These three muscles draw the fingers, into which they are inserted, towards the thumb. There are four interossei externi, for a small muscle, which supports the fore finger, the semi interosseus indicis of Winslow, the prior indicis of Albinus, is included. This muscle then may be styled the first; the second is the prior; and the third the posterior medii. The fourth is the posterior annularis. It is useless to be more minute in these unimportant muscles. They may be cut through with little danger, and will unite with as little trouble.

In the feet several small muscles fill up the four interstices between the metatarsal bones, after the same manner as in the hand. Like the interossei of the hand, there are three internal and four external. Their uses also similar.

INTERPELLA'TUS MO'RBUS, (from *interpello*, to interrupt). A disease attended with irregular or uncertain paroxysms. Paracelsus.

INTERPOLA'TUS DI'ES, (from *interpolo*, to renew). Days interpolated between two paroxysms. Paracelsus.

INTERSCA'PULUM, (from *inter*, between, and *scapula*, the shoulder blade). See SCAPULA.

INTERSE'PTUM, (from *inter*, between, and *septum*, an inclosure). See UVULA and SEPTUM NARIUM.

INTERSPINA'LES CO'LLI, (from *inter*, between, and *spina*, the spine). Winslow calls these muscles *spinales colli minores*. Dr. Hunter calls them *interspinalis*, adding, that they lie between the spinal processes of the neck and loins, serving to erect the body, by bringing the spinal processes nearer to each other. The *interspinales*, *dorsi*, and *lumborum* are tendinous, and connect the spinal with the transverse processes.

INTERTRANSVERSA'LES MU'SCULI, (from *inter*, between, and *transversales*, the transverse processes). They lie between the transverse processes of the cervical and lumbar vertebræ, serving to bend the neck and body to one side. Winslow calls them *transversales minores*. To the first of these muscles the name *concutiens* has been given.

INTERTRI'GO, (from *inter*, between, and *tero*, to rub). *Attrita*, *attritio*. A GALLING, or erosion of the cuticle, or of the skin. Children are apt to have excoriations behind their ears, in the neck, and thighs: the last often arise from neglect. The excoriated parts should be bathed frequently with warm water; and powdered chalk, or cerusse sprinkled on them through a bit of fine muslin when quite dry. Dr. Cullen considers it as a variety of erythematous inflammation.

INTERVERTEBRÆ LES MUSCULI, (from *inter*, between, and *vertebra*). They arise from the body of one vertebra laterally, and are inserted, after an oblique progress, into the back part of the other vertebra, immediately above it. They draw the vertebræ nearer to one another, and a little to one side.

INTESTINA TERRÆ. See **LUMBRICUS TERRESTRIIS**.

INTESTINA, (from *intus*, within). The **INTESTINES**, *chordæ*, and *phantices*. From the pylorus to the anus is one continued canal, divided into the small and great intestines, covered by the mesentery and mesocolon; and, as they are longer than these membranes, they are contracted in folds to the length of the latter. The whole length of the intestines is between seven and eight times the length of the body; the small ones are about five of these parts. The small intestines called *dertron*, and *cholades*, because they contain bile, are named **DUODENUM**, **JEJUNUM**, and **ILEUM**, q. v.: the large intestines are, the **CÆCUM**, the **COLON**, and **RECTUM**, q. v.

The first coat of the intestines, the external, is from the peritoneum, called *cellulosa tunica Ruyschii*; *tunica externa vel membranosa*; the second is the muscular coat formed of two planes of muscular fibres, the one thin and longitudinal; the other thicker, in a cylindrical direction: the third is styled the nervous, but consists of cellular substance; the fourth the villous, *peristroma*. The villi are of different shapes and lengths in different parts of the intestines, more thick in the small, more long and thin in the large ones; they are thought to be secreting and absorbing organs, as there the arteries seem to terminate, and the veins to begin.

The glands of the intestines, *enteradenes*, are supposed to be lodged in the nervous coat, next the villous, and are divided into *glandulæ solitariæ* and *aggregatæ*; but their existence is not clearly established.

In the great intestines we may observe little holes, which, when inflated, lead to cells analogous to the follicles of Malpighi; and by analogy we may suppose glands to exist in the great intestines near the anus, to separate a lubricating mucus, for facilitating the passage of the *fæces*.

The arteries and veins run together on the intestines.

In the intestines the first digestion is completed; from them the chyle is absorbed, and through their cavity the *fæces* ultimately carried off. These actions are performed by their peristaltic or vermicular motion, which apparently moving their contents backward or forward, in effect propel them; as the waves of an increasing tide sometimes fall short of, and at others gain on those which preceded them, but on the whole advance. This motion is caused by the successive contraction and relaxation of the circular fibres of the muscular coat; and the principal stimulus to this motion is the distention of the canal.

The action of the lungs on the diaphragm and of the abdominal muscles assist the progress of the contents of the stomach and intestines. Thus the *clara lectio*, reading aloud, is said by Celsus to assist digestion.

INTESTINALIS, (from *intestina*, intestines). Belonging to or proceeding from the bowels.

INTESTINALIS ARTERIA. See **DUODENALIS ARTERIA**, and **GASTRICA DEXTRA ARTERIA**.

INTESTINALIS VENA. See **DUODENALIS VENA**.

INTESTINORUM SOLA MËN. The *semen anisi*, according to Hoffman; and the *oleum anisi*, according to Van Helmont.

INTESTINORUM TUNICA EXTERNA, and **MEMBRANOSA**. See **INTESTINA**.

INTOXICATIO, (from *τοξικον*, poison, venom). It is properly the same as *infectio*, but generally synonymous with *inebriation*. See **INEBRIANTIA**.

INTRA FOLIA CEUS, (from *intra*, and *folium*, a leaf). Growing within the side of the leaf.

INTRASPINALIS, (from *intra*, and *spina*, the spine). See **INTERSPINALES**.

INTRATRANSVERSA LIS. See **INTERTRANSVERSALES**.

INTRICATUS, MUSCULUS, (from its intricate folds). See **ABDUCTOR AURIS**.

INTRINSECI, (from *intra*, and *secus*, towards). Painful disorders of the internal parts.

INTRITUM, (from *interior*, to be rubbed,) *entrimma*; a culinary term for minced meats, or rather such as are prepared by pounding, as potted beef, &c.

INTROCESSIO, (from *introcedo*, to go in). See **DEPRESSIO**.

INTROSUSCEPTIO, (from *intra*, within, and *suscipio*, to receive). Slight degrees of *introsusceptio* seem to occur frequently, and are soon restored; but even when in a considerable degree, the functions of the intestines are often not disturbed. Unless inflamed, or adhesions are formed between the external part, and that "received within," no disease seemingly follows. It occurs often so low in the rectum, that it may be reached by the finger, or the *received* intestine may be even protruded. Monro, Edinburgh Medical Essays. See **ILIACA PASSIO**.

INTSIA. *Mimosa intsia* Lin. Sp. Pl. 1508. A large evergreen tree in Malabar, called also *acacia Malabarica globosa*. The juice of the leaves, and bark is used to relieve pains in the bowels. See Raii Historia.

INTUMESCENTIÆ, (from *intumesco*, to swell,) *tumidosi*. Disorders attended with a swelling of the body, or a considerable part of it; the second order of the *cachexiæ*.

INTUSSUSCEPTIO, the same as **INTROSUSCEPTIO**, q. v. See **ILIACA PASSIO**.

INTYBUS, (from *in*, and *tuba*, a hollow instrument, from the hollowiness of its stalk). A name for the *cichorium latifolium* sive *endivia vulgaris*.

INULA. See **ENULA**.

INUCTIONIO, (from *inungo*, to anoint). **INUCTION**. The action of anointing, or the materials which are employed.

INVASIO, (from *invado*, to attack,) *accessio*.

INVERECUNDUM OS, (from *in*, not, and *verecundus*, modest; because the os frontis is regarded as the seat of impudence). See **FRONTIS, OS**.

INVERSIO UTERI, (from *inverto*, to turn inwards). See **PROCIDENTIA UTERI**.

INVIDIA, (from *in*, and *video*, to look upon, a nimis *intuendo fortunam alterius*). Envy; a depressing passion arising from a consciousness of the superior advantages of another. It induces debility, indigestion, and hectic.

INVOLUCRA, (from *involvero*, to fold in; from coming next after the child). *Secundines, hysteria, membrana*.

They form an universal covering for the fœtus, and the water in which it floats during pregnancy. They consist of the membranes called CHORION, and AMNION; the PLACENTA, and part of the FUNUS UMBILICALIS, vide in verbis.

If in labour the membranes do not break immediately upon their being pushed into the vagina, they should be allowed to protrude still further in order to dilate the os externum.—If they suddenly burst, and discharge much water, and the pains soon slacken, the labour becomes tedious. While the head of the child is yet covered with the unbroken membrane, it is smooth, soft, and slippery to the touch. Sometimes when the head presents the fontanel feels puffy, and deceives us, as it is mistaken for the membranes; but this should be carefully distinguished. If during labour the waters push the membranes down in an oblong form, the birth will be tedious: A short broad, or round form is the best.

INVOLUCRUM, (from the same,) the calyx of an umbelliferous plant. See also PERICARDIUM.

ION, (from *Ionia*, its native place). See VIOLA.

IONIA. See CHAMÆPITYS.

IONTHLA'SPI, *lunaria*. It is *clypeola ionthlaspi* Lin. Sp. Pl. 910; found in France, Italy, and Spain, said to be detensive, aperitive, &c. but not at present used.

IONTHOS, (from *ion*, the violet). The Grecian appellation of those hard pimples in the face of a violet colour, which the Latins call by the name of *varas*, and *gutta rosacea*.

IOSA'CCHARUM, (from *ion*, the violet, and *saccharum*, sugar). SUGAR of VIOLETS.

IOTACISMUS, (from *ιωσα*, the Greek letter *i*). A defect in the tongue or organs of speech, which renders a person incapable of pronouncing his letters; or where the letter *i* is frequently and rapidly pronounced.

IO'UI. A restorative alimentary liquid prepared in Japan. It is made from the gravy of half roasted beef, but the other ingredients kept a secret.

IPECACUANHA, (Indian). *Brasiliensis radix*, *herba parvis Brasiliana*, *polycocos*, *poaio do matto*, *caapir*; *cipo*; *Indiana radix*, *periclymenum parvum*, IPECACUAN, or BRASILIAN ROOT. Many of these names have been assigned, from the opinion of naturalists, respecting the plant which produces this valuable remedy. It has been supposed to be the root of a viola, of a periclymenum, and of a species of *psycotria*. Indeed the evidences in favour of the latter are so strong, that we have much reason to believe that its roots are at least emetic, though not the real ipecacuanha. In fact, if we can trust Decandolle's description in the Bulletin des Sciences, the *white* ipecacuanha is derived from the viola, and this medicine is afforded by three species, the *v. calceolaria* of the *speciès plantarum*, a native of Guiana and the American islands; the *v. parviflora* of the *supplementum plantarum*; and the *v. ipecacuanha* of the *mantissa*. These roots may be found among those of the true ipecacuanha, but they are a fraudulent addition, as, though emetic, they do not possess the valuable properties of the true or grey kind. They are distinguished by the size of the woody part, which, in the true kind, is a fibre only; in the white it is as thick as the bark. The roots of different species of *aselepias*, *dorstenia*, and other genera, are sold as ipecacuanha, but with the distinction of "*false*."

In 1780 Mutis sent to the younger Linnæus, from

South America, a full description of a plant, which he was assured was the true ipecacuanha; an account confirmed by a medical resident, who has been stigmatised with the name of an *empiric*. This naturalist referred it to the genus *psycotria* with the trivial name of *emetica*, doubting, however, whether it was the same with the ipecacuanha of Piso and Margraave, though the figures of these authors greatly resembled it. Dr. Woodville, in 1793, published an engraving of a specimen preserved in spirits, sent from the Brasils. The root was entire, and ascertained it to be the real plant; but the flower was wanting, so that the truth of Mutis's narrative and the credit of his informant could neither be established nor invalidated. In this state of uncertainty, we received in 1802 the description of the true plant from Felix Avellar Brotero, in the sixth volume of the Linnæan Transactions, p. 137. The author is professor of botany in Coimbra, and professes to have drawn his description from numerous dried specimens, corrected by the observations of his friend Bernard Gomes, a diligent medical botanist, who has often examined the living plants. They grow in Parnambuqui, Bahia, &c. and other provinces of Brazil, flower in November, December, and January, and again in February and March. The berries ripen in May.

It is scarcely the object of this work to transcribe the minute description of Brotero, which would be uninteresting to the medical reader; and we shall prefer making a few remarks on the minute difference between the *callicocca ipecacuanha*, the title he gives it, and the *psycotia emetica* of the younger Linnæus. This genus *callicocca* belongs to the *rubiaceæ* of Jussieu, and the species are all perennial.

The description of Brotero greatly resembles that of Mutis. In the latter, the bractæ which separate the florets are said to be so small as to be scarcely discernible; but Brotero describes the bractæ, involucri and flosculorum longitudine; but we have long since learnt that plus vel minus non mutat speciem. The stipulæ, according to Mutis, are awl shaped, and horizontal; in Brotero appressæ sessiles sublineares partito fimbriatæ, lacinulis subulatis. In Mutis the flowers are said to be axillary; in Brotero terminal. In Brotero's figure, however, there is but a single flower which, though placed terminally, is apparently axillary. The stipulæ in Sir Joseph Banks' plant seem to resemble those described by Mutis.

There appears, if these circumstances only are considered, little doubt but that the plant of the younger Linnæus is a variety of that described by Brotero; but in Mutis' plant there is no involucrium: in that of Brotero a large and strongly marked one, so that in reality, they must be two distinct species, though they certainly belong to the same genus. The involucrium is, indeed a part of the essential character in Schreber, and in the *cephælis* of Willdenow (the same genus); yet many of the species have naked heads. It has, in conformity with the same views, been proposed to add as a species of *callicocca* the *e. mutisii* (*psycotria emetica* Lin. Filii Supplementum Plant, p. 144). Head naked peduncled; few flowered; leaves lanceolate, smooth; stipules entire, awl shaped; corolla five, cleft; chaffy bractes, very small.

It is brought from the Spanish West Indies. Four sorts are mentioned, viz. the grey, brown, white, and yellow. The grey is generally esteemed the most valuable, but

Neumann assures that the brown is equally good. The white sort is much weaker than the other, and the yellow does not act in the least as an emetic, being merely purgative. The Peruvian sort is called *bezuguillo*.

The roots of the grey sort are about the thickness of a small quill, very unequal and knotty; variously bent and contorted, full of wrinkles and deep circular fissures, which reach down to a small whitish woody fibre that runs in the middle of each piece: the cortical part is compact, brittle, looks smooth, and resinous on breaking. They have little or no smell, the taste is bitterish and subacid, covering the tongue as it were with a kind of mucilage. The roots of the brown kind are small, somewhat more wrinkled, of a dark colour without, and white within. The white is woody, has no wrinkles, and, to the taste, no perceptible bitterness. The ash coloured or grey ipecacuanha is generally preferred: the brown has been observed even in a small dose to produce violent effects; but the white has scarce any effect, whatever the dose may be. The root contains a gummy and resinous matter, though the gum is in the greatest proportion, and the most active part: the bark is more powerful than the wood; and the whole root manifests an antiseptic and astringent power. The emetic quality is said by Dr. Irvine to be counteracted by the acetous acid; for thirty grains, taken in two ounces of vinegar, produced only some loose stools. For this reason it has probably become fashionable to add the ammonia, which is supposed to increase the emetic power of the ipecacuanha.

This medicine is the most certain, the mildest, and safest emetic with which we are acquainted; for it readily passes off by stool, if it does not operate by vomit; but perhaps less certainly by urine or perspiration than the antimonials.

The larger compact roots that have a resinous appearance are preferred. The slender, blackish, brown ones, full of fibres, are the worst. Mr. Henry, of Paris, has lately ascertained, by experiment, the fact first mentioned by Lassone, that the ligneous part is equally powerful with the cortical.

The roots of the caapia, commonly sold under the name of white ipecacuanha, are yellowish, or of a yellowish white colour. The apocynum is another imposition which we have mentioned; but the colour of its medullary fibre is of a deep reddish yellow colour, whereas that of the ipecacuanha is whitish, or of a pale gray.

Helvetius first brought this root into repute as an antidysenteric, though it was brought to Europe about the middle of the seventeenth century. Since his time it has been used in diarrhœa, mênorrhagia, leucorrhœa, in long continued obstructions, and in spasmodic asthma. In violent paroxysms of the latter it has procured relief; and where habitual, from three to five grains may be given every morning, or from five to ten every other morning, and continued for four or six weeks. Small doses of one to two grains have been of use in catarrhal, some consumptive cases, and various states of fever. It has also been employed in the cure of agues as an emetic, given at the time of accession, or at the close of the cold fit. Very small doses, as one third or one half of a grain, have been recommended every four hours, in mênorrhagia, cough, pleurisy, and hæmoptoe; and in

larger doses, to counteract the effects of opium. Of all its preparations, the powder is the best; six or eight grains of which will produce two or three discharges by vomit; and in diarrhœas and dysenterics, after this operation, it excites perspiration, if the patient is kept warm. It chiefly operates as an emetic in proper doses; in smaller doses, as a nauseating and aperient medicine, upon which its antidysenteric power seems to depend. It is said to succeed equally well in small as in large doses; but the quality of the root we now obtain is not the same, or it has lost this power. It is so certain an emetic, that we cannot venture to give it where vomiting would be injurious. Geoffroy supposed that the resinous part only was emetic, and that the virtue of the ipecacuanha in dysenteries depended on its gum, which acted as a demulcent; but this is highly improbable, as other emetics or similar medicines in nauseating doses are perhaps equally effectual. Dr. Irvine found the gum more actively emetic than the resin, and the bark than the wood, though the latter possessed this power in an inconsiderable degree. Water distilled from it was not emetic, but the remaining decoction violently so, though its peculiar properties were destroyed by long boiling. See Cullen's *Materia Medica*.

The best menstruum for extracting the whole virtue of the root is one part pure spirit, and two or three of water; of wines the Canary or mountain best extracts its virtue; but the London College directs the following *VINUM IPECACUANAË*. Take of the roots of ipecacuanha in powder, two ounces; of Spanish white wine, two pints; digest ten days, and strain. Ph. Lond. 1788. Its dose, as an emetic, is from \mathfrak{z} ij. to \mathfrak{z} i. ss.—as a diaphoretic, from twenty to forty drops, adding about ten drops of tinctura opii.

Dr. Alston thinks that the virtue of this root resides not in its oil, gum, or resin, but in its peculiar spirit. Later chemists, however, particularly Mr. Lassone and Mr. Henry, of Paris, have shown that ipecacuanha contains a free acid of a vegetable nature decomposed by fire, and different salts with a calcareous basis. It also contains a small proportion of an elastic gum. The most active part is the resin, though the extractive is by no means without power, in about a double dose. If three grains of powdered ipecacuanha are added to fifteen grains of jalap, it more certainly and efficaciously purges; but it also often deceives by producing vomiting.

To deceive children \mathfrak{z} i. or \mathfrak{z} ss. of powdered ipecacuanha may be infused in half a pint of boiling water, adding a little milk and sugar. A tea cup full may be given every ten or fifteen minutes, till it operates; and it will then need nothing to work it off. It might perhaps be better infused with weak coffee, or to this a tea spoonful of ipecacuanha wine may be added. The college also orders the following *PULVIS IPECACUANAË COMPOSITUS*. *Dover's powder*. Take of ipecacuanha, hard purified opium, of each, rubbed into powder, one drachm; of vitriolated kali in powder, an ounce. Pharm. Lond. 1788. The dose is from ten to thirty grains; the former dose containing a grain of opium. This is very nearly the same as the powder of Dr. Dover, and is considered as one of the most certain sudorifics in rheumatism, gout, and other diseases where sweating is necessary.

See Lewis's *Materia Medica*; London Medical Observations and Inquiries, vol. i.; Neumann's *Chemical Works*; Woodville's *Medical Botany*.

IPHION. See *ASPHODELUS LUTEUS*.

IQUETAIA. See *SCROPHULARIA AQUATICA*.

IRA, (from the Hebrew term *chirah*). ANGER quickens the pulse, and hurries respiration, and for a time increases the tone of the whole system. The stomach and bowels are greatly affected; and a stricture on the gall ducts is sometimes produced, so that a jaundicè is the consequence; though more frequently the gall is determined more copiously to the duodenum, producing disagreeable complaints in the bowels. Anger also produces hæmorrhages from the nose, the lungs, the vessels of the brain occasioning apoplexy, and the hæmorrhoidal vessels, particularly in those who are disposed to these evacuations.

During the fit of anger, or its immediate effects, it is said that vomits and purges should be avoided, though few take them in a passion; nor can we see what injury would be produced if they were given.

Anger, called justly "a short madness," will gradually cool; and should any bad effects be left, they must be treated according to their nature.

IRACUNDUS MUSCULUS, (from *ira*, anger). See ABDUCTOR OCULI.

IRINGUS, ERYNGO. See *ERYNGIUM*.

IRIS, (from *εἶρα*, to show). A RAINBOW. The forepart of the choroides of the eye, named from the variety of its colours. It lies floating and loose; is convex on the anterior, and concave on the posterior part; the perforation in its middle forms the pupil. The iris, by contracting or dilating, excludes or admits of light in such proportions as the variety of circumstances may require. Two orders of muscular fibres are found between the laminæ of the iris; one circular, the other radiated, which produce these actions. See UVEA, CHOROIDES, and CIRCULUS ARTERIOSUS.

The operation of cutting the iris is required when a cataract adheres to it; and when, from the contraction of its muscular fibres, the pupil is closed up, a disease called *synizesis*, or *caligo pupillæ*, is produced. Mr. Sharp, in his *Operations*, chap. xxix. directs the operator to proceed as follows: Place the patient as for couching; open and fix the eye with the speculum oculi; then introduce the knife in the same part of the conjunctiva that is wounded in couching; insinuate it with its blade held horizontally, and the back of it towards you, between the ligamentum ciliare and circumference of the iris, into the anterior chamber of the eye; and, after it is advanced to the further side, make your incision quite through the membrane; and, if the operation succeeds, it will, upon wounding, fly open, and appear a large orifice, though not so wide as it becomes afterwards. Mr. Sharp further observes, that when the pupil is contracted from a paralytic disorder, this operation cannot be encouraged.

IRIS. A species of rash, included by Dr. Willan in his third order of exanthemata; but we have not yet received his description and explanation. We may find an opportunity of resuming this subject, if the number appears in time. See CUTANEI MORBI.

IRIS, (from the resemblance of its flower to the rainbow). It is a perennial plant, with long, narrow,

sword like leaves standing edgewise to the stalk, and large naked flowers divided deeply into six segments, of which alternately one is erect, and another arched downward, with three smaller productions in the middle, inclosing the stamina and pistil: the roots are tuberous, irregular, and full of joints. (See *ERYSIMUM*.) It is a name likewise of the hedge mustard, *hermodactylus*; a kind of ginger; a species of *xyphium*, and of a *pastil*, consisting of alum, saffron, myrrh.

IRIS FLORENTINA. FLORENTINE ORRIS; *iris Illyrica*, and WHITE FLOWER-DE-LUCE, *iris florentina* Lin. Sp. Pl. 55. It is supposed to be only a variety of the common iris; but its roots are brought from Italy, as superior to our own. They are in oblong, flattish pieces, freed from the fibres, and brownish externally, but with brownish specks internally, and easily reduced to a farinaceous powder.

The root, in its recent state, is nauseous, acrid, and purgative, but loses these qualities by drying. The dry root is unctuous, bitterish, and pungent; the taste not strong, but durable; with a light, agreeable smell, which resembles violets, or rather raspberries; and communicates a similar flavour to spirits and to wines. As a medicine, the fresh root is a powerful cathartic; and its juice has been employed in the dose of ζ i. in dropsies: when dry it is a demulcent, and an expectorant, attenuating viscid phlegm, and promoting its discharge; but Dr. Cullen considers it as insignificant in this state. When cut in the form of peas it is used for promoting the discharge in issues.

In distillation it yields all its flavour to water; its bitter remaining in the extract. Rectified spirit brings over a part, and the extract is bitter and pungent in the mouth. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

IRIS TUBEROSA, vel BULBOSA. See *HERMODACTYLUS FOLIO QUADRANGULO*, &c.

IRIS FÆTIDA, *spatula fetida*, *xyris*, *gladiolus fetidus*, SPRUGE WORT, STINKING GLADDON, or GLADWYN; *iris fetidissima* Lin. Sp. Pl. 57; a wild species of iris, distinguished by a strong smell, found in hedges, &c.: its root is thick, and spreading in the earth, with many fibres, from which spring numerous leaves, longer, narrower, and sharper pointed than the common iris. The root is diuretic, but seldom noticed.

IRIS PALUSTRIS, *acorus adulterinus gladiolus luteus*, *pseudo acorus*, *pseudo iris*, *butomus*, *butomon*, YELLOW WATER FLAG; *iris pseudacorus* Lin. Sp. Pl. 56. It is common by the sides of rivulets and marshes; the roots are reddish; several flowers, of a yellow colour, stand on a stalk; the middle ribs of the leaves are prominent.

The roots of this species, when fresh, are more acrid, and strongly cathartic, than the former. Eighty drops of the expressed juice, repeated every two hours, have purged, when jalap, gamboge, and mercurials have failed. The root is without smell, but has an acrid styptic taste; its juice in the nose and mouth creates a burning heat, accompanied with a copious discharge, and is consequently considered as an errhine and sialogogue: from its astringency, it has been used in diarrhœa; for making ink, and dying black. To serpiginous eruptions, and scrofulous tumours, the expressed juice is said to be an advantageous application. Bergius

observes, that, when fresh, it is a hydragogue; when dried, an astringent: but like the other species, it is too variable in its strength to be received into general use.

IRIS LATIFOLIA TUBEROSA. See ZINGIBER.

IRIS VULGARIS; *iris hortensis nostras;* *iris Germanica* Lin. Sp. Pl. 55; *iris purpurea*, the COMMON PURPLE IRIS. Several blue or purple flowers stand on one stalk; their arched segments bearded with a yellowish matter. The plant is a native of the mountainous parts of Germany, common in our gardens, and flowers in June. The roots, when fresh, smell disagreeably, have an acrid nauseous taste, and are a strong irritating cathartic. The expressed juice has been given in a dropsy, from two to four drachms diluted with water. By gently inspissating the juice it is less active; but, if inspissated to dryness, it loses its purging quality. The dried root resembles in smell and taste the Florentine species.

IRRADIA'TIO, (from *irradio*, to shine upon). See ACTINOBOLYSMUS.

IRREGULA'RIS, (from *in*, and *regularis*, regular). A disease anomalous in its paroxysms.

IRRITABILITAS, (from *irrito*, to provoke). *IRRITABILITY*; the *vis insita* of Haller, *vis vitalis* of Gorter, *oscillation* of Boerhaave, *tonic power* of Stahl, and the *inherent power* of Cullen. It means that susceptibility to contraction which is peculiar to muscular fibres. We chiefly speak of it when morbidly increased, and in this state it may exist without or with inflammation. In the former state it is called spasm; in the latter, it is considered as a symptom only. Parts scarcely sensible or irritable in a natural state, become highly so in consequence of inflammation.

Irritability, according to Haller, differs greatly from sensibility; for many irritable parts are not sensible; and organs which are both irritable and sensible have by no means these qualities in the same or any proportional degree. The intestines, he remarks, are less sensible than the stomach, though more irritable; and the heart is an organ peculiarly irritable, though by no means sensible. In the language of this physiologist, cellular is often considered as synonymous with nervous, and, both in the French and German authors, the cellular substance is spoken of as an important organ, often as an irritable one. We have already offered our opinion, that it is merely an insensible connecting medium; nor have we been ever able to ascertain that it has any other office, or any appropriate function. The cellular, or rather the membranous parts, he considers as irritable, particularly the ligaments, the periosteum, the dura and pia mater, and the other membranes. The tendons possess, he thinks, no irritability; and, though the smaller arteries may possess this quality, he did not discover it in the aorta. The veins, the excretory ducts, the gall bladder and its ducts, the urethra, and ureters, he found only irritable in an inconsiderable degree; but the glands, the mucous sinuses, the uterus, the genitals, the œsophagus, the stomach, the intestines, the muscles, and particularly the diaphragm, are highly irritable. This principle he supposes to be owing to the mucous matter interspersed among the muscular fibres, and to be wholly independent of volition. Other authors have attributed irritability to a particular set of nerves not under the influence of the mind. It is

certain that it may be destroyed by drying; by coagulating the oily fluids of our system; by opium, belladonna, tobacco, &c.

The high reputation of Haller has induced us to enlarge on his opinions much farther than their real merit would require. His experiments were made on animals, often cold blooded ones, and in a state of health. He seems never to have looked at the human body in a state of disease, as the source of his observations; but had he done so, he would have found numerous facts in the most decided contradiction to his experiments. No part, not the eye itself, is more sensible than, for instance, the membranes when inflamed; no part shows greater irritability, either from passions or the stimulus of a gall stone, than the biliary ducts. The idea, that irritability is owing to the mucus in the interstices of the muscular fibres, is gratuitous and imaginary. Irritability is a property of life; but by what means does this mucus acquire life, and by what function, except this fancied one, does it show any vital power? The existence of different sets of nerves giving irritability is wholly imaginary, without the slightest support from anatomy.

Irritability, as inseparable from life, must be connected with the nervous power; but the nerves, we know, are not irritable. It must then owe its existence to the nervous influence, or the muscular fibre must differ from the nervous by some peculiar organization on which this property depends. There is little doubt of the muscular power depending on organization; for the muscle differs only from the tendon in structure. The fibres pass on, and may be traced from one to the other. Organs, at first in a great degree muscular, become, by age, more tendinous; so that, in the latter, the fibres are apparently more compacted, in fact, of an organization essentially different. Is then the muscle wholly nervous, or an organ only excited to action by nerves? Dr. Cullen thinks it wholly nervous, and calls muscles *the moving extremities*, in opposition to the *sentient extremities* of nerves; and the weight of evidence is strongly in favour of this opinion. We have said that we know of animal matter but in two forms, fibrous and cellular substance, more or less condensed. The fibrous seems exclusively nervous, and the nerves are closely compacted as in membranes, or more loosely organized in muscles. It is equally difficult to understand the construction of muscles, whether we supposed them nervous, or animal matter of any other kind.

Though we cannot ascertain the structure of the organs possessing irritability, we may shortly mention the laws by which it is regulated; and we shall find them so analogous to those of sensibility, that there will be little difficulty in recognizing the source to be similar. Irritability, like sensibility, is exhausted by exercise, and recruited by sleep; but, unlike sensibility, its exertions are alternated by relaxation. It is probable that the nerves in the muscular organs are in a higher state of excitement than in the sentient; for muscular organs are constantly, in a certain degree, exerted in order to counteract the antagonizing muscles, but unless the action is occasionally remitted, it is spontaneously relaxed. This constant state of tension is called the *tonic power*, and is in proportion to the general excitement. It presupposes irritability, in consequence of organization, which has been called the

inherent power, and is probably the same with the *nervous power* of physiologists: it must be so if muscles are only the "moving extremities of nerves." Irritability, as a morbid affection, however, implies a very different state, and has been styled *mobility*, a susceptibility of action from slight and otherwise insufficient stimuli; and this susceptibility, connected generally with debility, is more readily alternated with relaxation producing convulsions.

Irritability, as we have just remarked, is exhausted by exercise, and it may be suddenly destroyed, so as to kill; for a flash of lightning will at once extinguish it in every organ. It is, however, recruited by rest, and, as modern physiologists, with some reason, have supposed, accumulated so as to occasion increased action. Many of the facts adduced may, however, be resolved into the effects of custom; for, when given actions are excited by a weak stimulus, a common power becomes, in comparison, inordinate. Thus the iris, accustomed to contract in the gloom of a dungeon, feels the common daylight as painful as the glare of a noon day sun would be to a person who has never been confined. This leads us to remark, that the irritability of each organ has specific stimulus, by which only it is excited. Ipecacuanha does not irritate the eye; and the acrid urine or bile excite only pleasing and healthy sensations in their appropriate organs; but in the brain produce phrenitis, or in the stomach, vomiting, with faintness, cold sweats, &c. In general, muscles which act more slowly and regularly, preserve their irritability longer than those which act with violence; for in these the irritability is apparently supplied as fast as it is expended. A certain degree of action, we have remarked, must be kept up in all muscles, to preserve their irritability, or rather the tonic power. Beyond, irritability is exhausted; below the due point, it is lost; and this point differs in almost all the different organs. Each has its appropriate action, which it can bear without injury, or even with advantage; and the irritability of each is exhausted more rapidly, in proportion to the continued action which it exerts. The voluntary muscles can bear a very considerable increase of action, because it is temporary: the involuntary ones, whose action must continue, soon lose their irritability after a short increase. See NERVI; MUSCULI; IRRITATIO, and CEREBRUM.

Haller on Sensibility and Irritability; Whytt's Answer to Haller; the Difficulties in the Modern System of Physic, with Regard to the Sensibility and Irritability of the Parts of the Human Body, by De Haen; Kirkland on the Brain and Nerves; on the Sympathy of the Nerves, and of different Kinds of Irritability; Cullen's Introduction to the Materia Medica.

IRRITA'TIO, (ab *irritare*). IRRITATION is a term to which different meanings have been affixed, and this has occasioned some confusion among pathologists. The most obvious idea of irritation is the action of a mechanical or a chemical acrid, as a thorn under the skin, or the effluvium of ammonia in the nose. Similar irritation is the effect of poison in the habit, as of cantharides; of altered secretion, as in gonorrhœa; of unnatural contents in the stomach, as in heartburn. Irritation, however, is discovered by its effects, when not obvious to the sense, as in cases of scirrhi, worms, ossifications, or extravasated blood; and, independent of these,

a peculiar state of the excitement of the nervous power occasions the most common impressions to become the source of pain and uneasiness. This state of excitement is sometimes owing to inflammation, which acts in a manner we shall afterwards explain (see NERVUS and TONUS); sometimes to latent sources of irritation in the brain, sometimes perhaps to a change in the state of the nervous power itself. We can no otherwise explain the effects of an east wind on some hypochondriacs, or a particular state of electricity of the air on persons peculiarly susceptible of its effects.

We have already had occasion to remark, that privations sometimes occasion what are called symptoms of irritation. Thus hunger produces restlessness and anxiety; the want of the degree of tension, either from external pressure or internal fulness, from the sudden emptying of any cavity, will occasion uneasiness, which has been styled a symptom of irritation. Internal feelings of this kind are sometimes opposed to pain; and the peculiar sinking in atonic inflammations, has been styled also a symptom of irritation, not, perhaps, with perfect propriety, but with sufficient distinctness when explained.

The effects of irritation are generally increased action; and, in the animal system, privations are, by an unaccountable solecism, considered as positive causes of increased action. This loose, illogical language arises from a want of distinction between increased and irregular action; for in spasms produced by causes destructive of life, in convulsions closing the last scene of mortal existence, it would be absurd to say that action, which always implies energy, is increased. We have already shown that in all these instances the power is diminished, and the action, in consequence, irregular. See CONVULSIONS and INIRRITANTIA.

IS, (*is, a fibre,*) its plural is *ves*. Hippocrates, and other writers, have used this term for both a fibre and a nerve.

I'SAROS. See ARUM.

I'SATIS, (from *ισαζω*, to make even, from its power in reducing tumours). *Sativa latifolia; tinctoria*. WOOD. See GLASTUM.

I'SATIS I'NDICA. See INDICUM.

ISATO'DES, (from *isatis*, and *ειδος*, likeness). Of the colour of woad.

I'SCA, (*ισχα*). A fungous excrescence of the oak, or of the hazel. The ancients used it as the moxa. See MOXA.

ISCHÆ'MON, (from *ισχω*, to restrain, and *αιμα*, blood). A name for any medicine which restrains or stops bleeding.

ISCHÆ'MON SATI'VUM. MANNA GRASS. See GRAMEN.

I'SCHIAS, (from *ισχιον*, the hip). A name of a rheumatic affection of the hip joint, called the *sciatica* or *ischiadicus morbus*, and of two crural veins, one of which is called the greater, the other the less. See CRURALIS VENA.

ISCHIA'DICUS DO'LOUR, (from the same). See ARTHRITIS.

ISCHIA'DICUS MO'RBUS, (from the same,) also called *ischias, sciatica, coxa dolores*. Aretæus ranks this disorder as a species of gout, "which comes," he observes, "on the hind part of the thigh, the ham, or the tibia; at other times attacking the acetabulum of the os femoris, and then the buttock and loins, seeming to be

any thing rather than a sciatica." Dr. Cullen ranks it as a synonym with rheumatismus.

The sciatica is sometimes seated in the tendinous expansion which covers the muscles of the thigh, occasionally, it is supposed, in the coat of the sciatic nerve. In the last case the pain is more acute and violent, attended with a numbness; a symptom easily accounted for. Its most common seat, however, is in the muscles, or in the capsular ligament; and it is then either rheumatic or gouty.

The two former species cannot be distinguished; nor do they admit of any peculiar treatment. In general, the disease must be treated as a rheumatism of the chronic kind, to which we refer. (See RHEUMATISMUS.) There are, however, some modes of relief supposed to be peculiarly useful in sciatica, which we must mention in this place. That recommended by Fothergill, consists in giving a grain of calomel every night, washed down with a draught containing twenty-five drops of tincture of opium, and thirty of antimonial wine. If not relieved after ten doses, the quantity of calomel is to be increased to two grains every alternate night. Other authors have recommended the ethereal spirit of turpentine, which is a very efficacious medicine, if united with honey, by gently melting over a slow fire; and in this way the dose may be increased to thirty or forty drops. We have found the combination of mercury and antimony, in the form of Plummer's pill, with the Lisbon diet drink, frequently succeed when every other medicine has failed; but these remedies we shall again mention when speaking of rheumatism.

The *ischias nervosa* of Cotunnio is supposed by this author to be owing to a fluid distending the sheaths of the nerves, and irritating the nervous fibres. The peculiar treatment suggested by this opinion is the application of a blister immediately under the knee joint, on the inside of the leg, as well as to the hip; as near the knee the blister affects more particularly the nerve in the neighbourhood of that part. There is little doubt of the existence of a sciatica not attended with any striking inflammatory symptoms; but of the peculiar cause assigned by Cotunnio we can find little support from observation or dissection. See Culleni Nosologia Methodica.

Richter speaks of some cases of the *ischias nervosa* being successfully treated by blisters often repeated, and sudorifics. In one instance, the blisters were applied on different parts where any pains were felt in succession: the sudorifics were first crude antimony, the stipites dulcamaræ in pills, and the warm bath for six days; on the seventh, a powder composed of camphor, ipecacuanha, and opium, was given, preceded by a tepid bath; the bath was continued till the foot became œdematous, and then left off; the other remedies were still pursued, which, in about six weeks, completed the cure. The symptoms were, pains in his arms, shoulders, and back, which settled about the hip joint, continued fixed, and increasing till the patient could not walk; the whole limb became shorter; the pains extended from the hip joint down to the foot; he felt as if ants were running about in the foot; and was totally unable to move the limb to either side, which, in other respects, was warm, and properly nourished. A lady and a young man were cured by the application of burning cones and blisters;

on which he remarks, that from this method nothing is to be expected unless in such kinds of lameness as proceed from the metastasis of any stimulating matter, where the lameness is accompanied with pains in the suffering limb, and chiefly the hip joint; and this morbid matter he thinks rheumatic or gouty; though, in some cases, he had reason to believe it was scrofulous. See his Medical and Surgical Observations, p. 169.

These cases, however, by no means support Cotunnio's idea of the cause. They are instances only of chronic rheumatism, though pains in the hip joint are, as he remarks, sometimes scrofulous, and occasionally, we think, of a cancerous nature.

ISCHIAS EX ABSCE'SSU, (from *ισχίος*, the hip). See ARTHROPOUSIS.

ISCHIAS SPARGANO'SI. See LYMPHÆDUCTUS.

ISCHIATOCE'LE, (from *ισχιατος*, the genitive of *ισχίος*, and *κελη*, rupture). Intestinal rupture through the sacro-sciatic ligaments.

ISCHIOCE'LE. A rupture between the os sacrum and the tuberosity of the os ischium.

ISCHIO-COCCYGE'US. See COCCYGEUS ANTERIOR.

ISCHION. The ligament which retains the head of the thigh bone in the acetabulum coxendicis.

ISCHIUM, os, (because it lies near *ισχίος*, the loin). *Coxendix cochone*; the HIP BONE. The extent of this bone may be marked by a horizontal line drawn through near the middle of the acetabulum coxendicis; for the body of this bone forms the inferior portion of the acetabulum. The great tuberosity on which we sit, as it advances forwards, becomes smaller, and gives origin to the corpora cavernosa, and the erectores penis or clitoridis; then the bone mounts upwards with a considerable curve, and is stretched out into its small leg. It forms the lower part of the pelvis. The tuberosity is large and irregular, covered apparently with a cartilage, which is in reality the tendinous fibres of the muscles inserted into it. Between the spine and the tuberosity is a cavity on which the obturator muscle plays, as on a pulley, defended by cartilage. The ramus of this bone, which passes forwards and upwards, makes, with the ramus of the os pubis, the foramen magnum ischii.

ISCHNOPHO'NIA, (from *ισχίος*, slender, and *φωνη*, the voice). A SHRILLNESS OF THE VOICE; but more frequently a hesitation of speech, or a STAMMERING; *psellismus hesitans*.

ISCHNO'TIS (from *ισχίος*, slender). LEANNESS.

ISCHURE'TICA, (from *ισχυρία*, a suppression of urine). Medicines that remove a suppression of urine.

ISCHU'RIA, (from *ισχω*, to retain, and *ουρον*, urine). AN ISCHURY, A STOPPAGE OF SUPPRESSION OF URINE. La Motte distinguishes between a retention and a suppression of urine. In the former, styled *strangury*, the patient hath frequent calls to make water; but voiding it, if at all, in very small quantities, and with difficulty. In a suppression there is seldom any inclination to discharge any urine; but, if any, the discharge is sudden, and almost involuntary.

In the true ischuria the bladder is full; in the spurious it is empty, for nothing descends from the kidneys.

Dr. Cullen places this disease in the class *locales*, and order *epischeses*, defining it an absolute suppression of urine. The species are,

1. ISCHU'RIA RENALIS, where, some disease of the kidneys having preceded, pain and an uneasy sensation of weight are felt in the region of the kidneys, without any swelling of the hypogastric region, or stimulus to make water.

2. ISCHU'RIA URETE'RIKA, where, to the same symptoms is added a sense of pain and uneasiness in some part of the course of the ureters.

3. ISCHU'RIA VESICA' LIS, when there is a tumour in the hypogastric region, pain at the neck of the bladder, and a frequent inclination to discharge urine.

4. ISCHU'RIA URETHRA' LIS, when there is swelling in the hypogastric region, a frequent desire to discharge urine, and a sense of obstruction in some part of the urethra.

The varieties of each species are added, and these will sufficiently explain the causes.

Varieties of the ischuria renalis are, *ischuria nephritica*, from inflammation of the kidneys; *nephrolitica*, from a stone; *nephroplethorica*, plethora; *lunatica*, *periodica*, *peridical*; *nephrospastica*, from spasms; *nephrohelminthica*, worms; *nephrothromboides*, coagulated blood; *nephrophyica*, purulence of the kidneys; *nephrophlegmatica*, mucus; *nephroplegica*, paralytic affection; *suppleta*, from some other evacuation supplied.

Varieties of the ischuria ureterica are, *ischuria ureterica*, from inflammation of the ureters; *ureterolithica*, from a stone; *ureterothromboides*, grumous blood; *ureterophlegmatica*, from mucus; *ureterophyica*, from pus; *ureterostomatica*, the closing of the inferior orifice of the ureters.

Varieties of the ischuria vesicalis are, *ischuria atretarum*, from the menstrua retained in the vagina, in consequence of an imperforated hymen; *cystica*, from inflammation of the bladder; *cystospastica*, a spasm of its sphincter; *cystolithica*, a stone; *cystoplegica*, paralytic affection; *cystophyica*, purulence; *cystothromboides*, grumous blood; *cystophlegmatica*, mucus; *cystoproctica*, from the rectum swelling, with scybala, calculus, flatus, inflammation, pus, or hæmorrhoids; *ectopocystica*, from a hernia of the bladder; *hystero-cystica*, from an inverted or retroverted uterus; *paradoxa morgagni epistole*; *polyurica*, from the bladder distended with urine a long time retained.

Varieties of the ischuria urethralis are, *ischuria aspiadialis*, from closing of the urethra; *carunculosa*, from caruncles of the urethra; *cryptopica*, a retraction of the penis within the abdomen; *hydrocelodes*, from a rupture of the urethra opening into the scrotum; *peridesmica*, a stricture of the urethra from a ligature; *perinæalis*, a tumour of the pirinæum; *phymosica*, a phymosi; *urethrelmintica*, worms; *urethritica* inflammation of the urethra; *urethrohymenodes*, a membrane impacted in the urethra; *urethrolithica*, a calculus impacted in the urethra; *urethroplegmatica*, mucus stuffing up the urethra; *urethromboides*, grumous blood; *urethrophyica*, pus.

To these idiopathic ischurias may be added some symptomatic ones, particularly those from general stupor, in consequence of apoplexy or narcotic poisons.

When the suppressed urine is lodged in the bladder, a pain and swelling is observed about the pubes. Relaxation, as a cause, is distinguished from stricture, by the little pain attending the disorder, by the introduction of the catheter, and by the fulness above the pubes.

If inflammation in the kidneys is the cause, some pain and heat may be observed in that region, though in general the kidneys are insensible. If a stone in the kidneys occasions the complaint, a vomiting is an attendant symptom; if in the bladder, a pain is felt there, recurring by paroxysms with great violence, as well as along the urethra; mucus, or pus, is excreted with pale urine; tenesmus is troublesome, and generally the stone may be felt if the catheter is introduced. If from inflammation in the neck of the bladder, there is pain in the pirinæum; the slightest discharge of urine gives an intolerable burning sensation; and if a finger is introduced into the anus, and turned towards the bladder, a tumour will be sometimes obvious.

If this disorder is the true ischuria, and violent, tenesmus, coldness of the extremities, vomiting, and a febrile pulse, constantly attend; but if of the spurious kind, there is no tension, but rather a sense of emptiness about the pubes. If it continue above seven days, or if from a wound of the spine, or luxation of its vertebræ, it is highly dangerous. If the smell of urine proceeds from the patient's mouth or nostrils, there is little hope. A hiccough is also an unfavourable symptom; but when no inflammation attends, the urine may be long suppressed, and the discharge again restored should there be no unconquerable obstacle.

The cure must be regulated by the circumstances and the cause of the complaint. If we can ascertain, from the preceding symptoms, that there is no water in either the bladder or ureters, and that the ischuria is truly renal, we must inquire whether it be owing to a palsy of the vessels or to a stone in the pelvis of the kidney. To determine this question, it is requisite to know whether any gravelly concretions have been discharged, or whether vomiting has attended. These will show that the disease is seated in the gland; and though each case occurs in the old and debilitated constitutions, we think the general torpor, the constitutional decay conspicuous in every function, will point out when it arises from palsy of the secretory vessels. In this case we have little room for hope, since this palsy is only one symptom of the general failure of the constitution. Our best chance of success in that case arises from blisters to the loins, the warmest general stimulants, with the most stimulating diuretics, as the ethereal spirit of turpentine. A temporary relief in this way we have obtained; and we have found the efficacy of this last medicine on the diseased part by its producing a discharge of blood, when it has failed in bringing back the secretion of urine. When it has succeeded most effectually, it has procured the discharge only for a short time, and it has then failed entirely. It has been supposed that blisters act from the absorption of the cantharides; but we have never found this medicine efficacious, except when in the bladder. It has never in our hands proved diuretic. In some instances, the secretion of urine has been suppressed in the young and strong without inflammation, or any obvious cause. A case of this kind is recorded by an American physician; and we have met with an instance where no urine was apparently discharged for six weeks; nor was there any vicarious evacuation, except a profuse sweat for a day or two; or the slightest suspicion of imposture, as the patient was in an hospital, and constantly watched. Medicine seemed to give no relief, and the discharge at last gradually returned.

When a stone in the pelvis of the kidney is the cause, we can gain nothing by the stimulating diuretics, except impacting the obstruction more firmly. Our best chance, though a slight one, is by anodynes and relaxants, abstaining as much as possible from fluids.

Obstruction in the ureters is felt, as we have said, from fulness in the hypogastric region, without any tension in the bladder. Internal sensations are, however, obscure; nor can we see how this fulness can be distinguished from flatus or an accumulation of fæces. A stone passing through the ureters generally occasions some numbness in either leg, and a retraction of one testicle in men, as it passes over the nerves which come down with the spermatic vessels. We know not that a fluid will produce any similar effect; but, unless by this means, it is not easy to perceive how a distention of the ureters can be ascertained. Were it possible to decide, it would not, we fear, greatly assist the practice. To increase the quantity of urine would be to add to the disease. If the suppression arises from a stone in the ureters, the pain will discover the cause, and point out the most effectual remedy, viz. opium; but should there be no pain, sedatives will more probably relieve than any violently forcing means. It is seldom, however, that a total suppression arises from obstructions in the ureters, since it can scarcely take place equally in both; and should one only be obstructed, the kidney on that side would soon lose its power, and its office be supplied on that side where the passage is free.

The most frequent causes of ischuria occur in the bladder. Many of these are mechanical, as when a calculus, impacted in the neck, obstructs the discharge; when an inverted or a retroverted uterus drag it backward and raise the orifice; when the head of a child, in its passage, rests on the cervix; when hardened fæces, or hæmorrhoidal tumours, press on the aperture. All these causes are readily discovered; and the treatment of each depending on them will be considered in other places.

Causes more immediately connected with medical practice are inflammation and spasm. The effects of inflammation we have seen to be suppression of urine, and this is relieved by anodyne clysters, fomentations, warm liniments, and even blisters to the perinæum. (See INFLAMMATIO VESICÆ.) Spasm is in part conquered by the same means; but opium may be more freely employed by the mouth and in clysters. Camphor in clysters promises to be an effectual remedy; but an alarming coma has, in two instances, followed. In this case, and in suppression of urine from many other causes, the action of laxatives will excite the usually corresponding action of the bladder; and walking on a cold wet floor, perhaps dashing water against the legs and thighs, would succeed in procuring a discharge of urine, as it has done the discharge of fæces. A tony of the bladder will sometimes occasion ischuria; but a more common effect is incontinence of urine. When it arises from atony, or a want of the contractile power, the catheter must be frequently employed to prevent the distention increasing the disease; warm stimulants applied to the perinæum and pubes, and stools procured by stimulating clysters. In this case cantharides must be avoided, for these act chiefly on the neck of the bladder; and the stricture of the sphincter in cases of ischuria from this cause is already greater than the power

of the other fibres can overcome. Internally, bark, with aromatics, should be given; but every attempt, either fails or procures only a temporary relief.

Cantharides, and sometimes acrid urine, by increasing this stricture of the sphincter, will produce the obstruction. In this case dilution, by frequent draughts of a warm liquid, warm fomentations to the pubes and perinæum, with opiates, will generally succeed.

When the urine is totally retained in the bladder, the introduction of the catheter immediately, whatever may be the cause, is too common; but whether this complaint arises from inflammation or from spasm, this conduct should carefully be avoided. Mr. Pott observes, that the best method of relieving this complaint, particularly when caused by spasm, is by evacuation and anodyne relaxation. The loss of blood, he says, is often necessary; but the quantity, the strength and state of the patient will determine. The intestines must also be emptied by some gentle cathartic; but the most effectual relief will be from the warm bath, or semicupium, the application of bladders half filled with hot water to the pubes and perinæum; and above all other remedies, the injection of clysters, consisting of the decoct. pro enemate and tinct. opii; or if after a due bleeding, and, if necessary, emptying the bowels, a free dose of opium is given, and the patient is seated in a warm bath during twenty minutes or half an hour, repeating this use of the bath more or less, as the case may seem to require, success will very rarely fail to attend; and if, by these means, the urine begins to drop through the urethra, although but a drop in a minute at the first, by persevering steadily and closely, the bladder will be effectually emptied. The great object, he observes, is to appease irritation and pain; and although some time be required in producing the effect, it will amply reward the practitioner's care and the patient's fatigue.

When great pain attends a retention or suppression of urine, the practitioner should first observe whether the kidneys have done their office, and whether in reality there is urine in the bladder; for, if full, it will be felt above the os pubis, and by pressure on it a pain will be excited in the neck of the bladder, or at the end of the penis. It sometimes happens that the bladder will contain a large quantity, without being greatly affected; at other times a very small quantity will produce great inconvenience; and inflammation, with symptoms of irritation, will ensue. Dr. George Fordyce observes, that much of the difficulty and pain from retained urine is from the more or less sudden filling of the bladder or distending it.

A bougie, or a catheter, is, however, often necessary, and the larger sizes of each are more easily introduced than the smaller. It is singular that the introduction of either should be sometimes attended with not only a shivering, but all the consequences of an intermittent paroxysm, viz. heat and sweating. In particular constitutions, this is constantly repeated whenever the operation is attempted; but pathologists have offered no explanation of the source of this singular appearance. The rules for introducing these instruments occur in the article CATHETERISMUS, q. v.

If no other method will succeed, a puncture may be made into the bladder, as directed in the article PERRINÆUM, *Puncture of the*.

Four methods have been proposed by different writers for drawing off the urine; 1. By an opening into the bladder above the os pubis. This plan, however, is confined to those cases in which the bladder is greatly distended. 2. By making a puncture through the perinæum into the bladder. 3. By puncturing the bladder laterally, as in the lateral operation for the stone. 4. By puncturing the posterior part of the bladder through the rectum.

Mr. Pott prefers the first method; but this, as we have said, is limited to particular circumstances. There is little ground of preference in either of the others; but we have found no very promising prospect of success from the trials hitherto made. Indeed, the operation is generally deferred till the patient's strength is exhausted, or until the parts from continued distention are hastening rapidly to mortification.

The ischuria urethralis arises from substances obstructing the canal; from inflammation, or from local complaints. The obstructions must be removed by bougies; and caruncles, or the more obstinate strictures, by caustics. Inflammation of the urethra is treated in the usual way; and ischuria, from a retraction of the penis, from inflammation, phymosis, or rupture, can be removed only by removing the causes.

See an instance of this disorder from a retroversion of the uterus, in the London Medical Observations and Inquiries, vol. iv. p. 388, &c. See Pott's Chirurgical Works; Lewis's Translations of Hoffman's Practice of Medicine; Bell's Surgery, vol. ii. p. 171; White's Surgery, p. 374; Memoirs of the Medical Society of London, p. 117.

ISLINGTON WATERS. See AQUÆ MINERALES.

ISORA-MU'RI. *Helicteres isora* Lin. Sp. Pl. 1366. The name of a tree in Malabar. The juice of its root has been used in disorders of the breast.

ISOTHE'ON. See DYONYSOS.

ISO'TONI, (from *ισος*, equal, and *τονος*, extension). See AEMASTICOS.

I'SPIDA. See ALCEDO.

I'STHMION, (from *ισθμος*, a narrow neck of land between two seas). The narrow passage between the mouth and gullet; sometimes the fauces.

ISTHMUS VIEUSSENI. The ridge which surrounds the remaining trace of the foramen ovale between the right and left atricles of the heart.

ITE'A. See SALIX.

ITINERA'RIUM, (from *itinerò*, to travel). A staff used in cutting for the stone. Hildanus.

IU'LUS, (plural IULI,) (from *ιουλιζα*, to shoot out). See AMENTACEI FLORES.

I'VA ARTHRI'TICA, (quasi *juva*, from *juvo*, to assist; as useful in expelling the gout). See CHAMÆPITYS.

IVABE'BA. An ancient shrub, the root of which is a good deobstruent. See Raii Hist.

I'VA MOSCHA'TA. See CHAMÆPITYS.

I'VA PECA'NGA. See SARSAPARILLA.

I'VRAY. See LOLIUM.

IXIA, (from *ιξος*, glue). *Varix*. A name of the *carlina*, or such of this tribe as yield a viscous juice. The *ixia*, or *ixias*, is represented as poisonous; but it is not clearly known to what plant these names belong. These species of *ixia* of modern naturalists are chiefly natives of the Cape, and cannot be the plants mentioned by the ancients. The *carlina*, one of the thistle tribe, was called *chamæleon*, from the very great variety of its leaves in different soils. (Pliny and Dioscorides.) Dioscorides calls the white variety *ιξια*, because a kind of glue (*ιξος*) is found at its root. Dios. lib. iii. cap. 10 and 11. Pliny, however, asserts, lib. xxii. cap. 18. that two plants are distinguished by this name, and that the *ιξος* is found in the axillæ; while Guilandinus contends that the *ixia* and *chamæleon* of Dioscorides, who, by the way, considers the former as poisonous, were different plants. Pliny informs us that the glue was used instead of mastich. Linnæus includes all the ancient species in his genera of *enicus*, or *attractylis*. The dispute, however, which has filled many pages, is trifling; and the outlines which we have here given will appear, perhaps, sufficiently satisfactory.

I'XIA, I'XINE, I'XION, (from the same). See CARDUUS PINEA.

I'XUS, (from the same). See APARINE.

J A L

JABOTAPI'TA. A tree in Brasil, which bears yellow flowers, and has a grateful smell. *Ocina jabotapita* Lin. Sp. Pl. 732. The fruit resembles our myrtle berries; they are astringent, and yield, by expression, an insipid oil. See Raii Historia.

JABUTICA'BA. A fine tall tree which grows in Brazil, but not described by botanists. Its fruit resembles an apple, and is gratefully cooling.

JA'CA I'NDICA. The Indian jacque jaca, or JACK TREE. Our predecessors have considered it as synonymous with MARUM, q. v. but seemingly without any authority. The jack is the Indian bread fruit tree, a species of artocarpus.

JACARA'NDA A'LBA, resembles the European palm tree, and grows plentifully in Brasil. The Brasilians make a pottage of it, which they call *manihay*; and it is supposed to be a stomachic. See Raii Hist.

JACARECATI'NGA. See CALAMUS AROMATICUS.

JA'CE BRASILIE'NSIBUS, *melo Indicus, patheca*, and *citrullus*. Ray considers it to be a species of *anguria* or *citrullus*, and calls it *water melon*; this fruit is as large as a man's head, covered with a green rind, and its pulp is well tasted. See CITRULLUS.

JA'CEA. *Centaurea jacea* Lin. Sp. Pl. 1293. Knap WEED or MATFELLON. The margins of the leaves are not serrated; the leaves and stalks are destitute of spines: it is common in pasture grounds, and flowers in July and August. A slight astringency is attributed to it.

JA'CEA ORIENTA'LIS PA'TULA. See BEHEN ALBUM.

JA'GRA. See PALMA COCCIFERA.

JA'LAPA, (from *Chalapa*, or *Xalapa*, a city in New Spain). **J**ALAP. *Gialapa, chalapa, xalapa, mecocahana nigra, convolvulus Americanus, bryonia Peruviana*. There is said to be a third species of jalap called *mutalista*, by the Indians *mathalistic*.

This plant is a native of Mexico, and found near the

city of Xalapa, from whence its name is derived; but it has since been discovered near Vera Cruz and on the south of Florida. It was carried by Michaux to the botanic garden in South Carolina, where an old root was found, weighing, when fresh, above fifty pounds. (Annales du Musæum National, vol. ii.) It was at first referred by Linnæus to the genus *mirabilis*, with the trivial name of *jalapa*; but observing the size and shape of the root of the *m. longiflora*, he was inclined (Amœnitates Academicæ, vol. vii. p. 308.) to think them the same; for no botanist had yet described the flowers of the officinal root. Bergius, on trial, found, however, that neither of these species was purgative, but that the root of the *mirabilis dichotoma* was so. To this plant then he referred the jalap; and, on his authority, the compilers of the Swedish Pharmacopœia did the same. Houston seems to have first shown that it was a *convolvulus*; and in this he was followed by Sir Hans Sloane, Miller, and at last Linnæus himself in the Mantissa of the System of Nature. It is, therefore, the *convolvulus jalapa* of the Mantissa and of Willdenow (vol. i. p. 860); but the only figure which shows the parts of fructification complete is in the second volume of the Annales of the National Museum. The author (Desfontaines), from its simple sloping stigma, suspects that it rather belongs to the genus *ipomœa*.

The roots are brought from New Spain in transverse slices; they are solid, hard, weighty, of a blackish or dark brown colour on the cortical part, internally of a dark greyish colour, with several black circular striæ.

The hardest, darkest, and those pieces which have the most numerous resinous veins; those that break most compact, shining, and that burn readily at the flame of a candle, are preferred. Worms rarely touch the resinous part: so, when the resin is only wanted, the worm eaten are not inferior.

Pieces of briony root are sometimes mixed with the jalap, but are easily distinguished by their paler colour and less compact texture, and by their not readily burning at the flame of a candle.

Jalap hath scarcely any smell, and little taste; but when swallowed it affects the throat with a slight pungency and heat, occasioning a spitting. In doses from ten grains to half a drachm it is an effectual cathartic, but gripes and nauseates less than the generality of purging medicines in use. For children in general, and adults of a leucophlegmatic habit, it is peculiarly

proper, though it is not unsuitable to constitutions of a different kind. It is diuretic as well as purgative, and consequently preferred in dropsies. Lewis thinks that the gummy part promotes a flow of urine, while the resin purges; but, from experiments made with this view, we did not find the distinction correct.

If well triturated with crystals of tartar before exhibition, it will operate, it is said, in smaller doses than when taken by itself, and without griping. Rubbed with hard sugar, it becomes a safe medicine for children; joined with calomel, in large doses, it is rendered one of the most powerful purgatives, either as a hydrogogue or anthelmintic; and, from its general efficacy in dropsies, was called *panacea hydroficorum*. The dose of the simple powder is from ℥ i. to ℥ ij. The compound powder may be double the quantity. It generally requires no corrector, but a little spice, or a few drops of some warm oil.

RE'SINA JALA'PII. *Resin of jalap.*—Take any quantity of powdered jalap root; pour upon it so much rectified spirit of wine as will cover it to the height of four fingers, and digest them in a sand heat; filter the tincture through paper; put it into a glass cucurbit, and distil off one half of the spirit; add to the remainder a proper quantity of water, and the resin will precipitate; divide it into little cakes, and dry with a gentle heat. This has no place in the Pharm. Lond. 1788; but the extract is directed to be made like the resinous extract of bark.

It is a pure resin: but its insolubility in any aqueous fluid forbids its use, except it is previously triturated with an alkaline salt, gum, sugar, or a similar intermede. If thus managed, a dose from gr. v. to x. operates with sufficient ease and efficacy.

The jalap which remains after this resin is extracted, gives out, by boiling in water, a mucilaginous substance, which is said to operate by urine, but not in any degree by stool. But this is asserted without foundation.

From sixteen ounces of good jalap Neumann obtained ℥ v. and ℥ iv. of pure resin; but in the shops it is frequently adulterated; and the methods of imitating it are so various, as to elude every known method of detecting the fallacy.

The advantage of the extract consists in the equality of its strength; for some of the roots afford only ℥ ij. while others afford ℥ v. of the resin in a pound. But, except for the convenience of form, the tincture, with proof spirit, will answer every purpose proposed by the gummy resinous extract of the college, which may be given from ℥ ss. to ℥ i.

Tincture of jalap is made by digesting eight ounces of powdered jalap in two pounds of proof spirit, with a moderate heat for eight days, then straining the tincture. The dose is from ℥ i. to ℥ ss.; mixed with syrup, it may be given to children with the greatest safety. This is the purgative said to be given by the inoculators who received their instructions from Sutton (Cullen's *Materia Medica*); and sufficiently certain in point of strength, as the menstruum does not extract the whole virtue of any kind of jalap. See Neumann's *Chemical Works*; Lewis's *Materia Medica*.

JA'LAPA A'LBA. See MECOACANA ALBA.

JAMES, DR. gave his name to a fever powder, since highly celebrated. With a disingenuity highly repre-

hensible he seems to have deviated from his original idea, and sold a medicine under the authority of a patient very different from the specification. He directs the antimony to be calcined in a flat unglazed earthen vessel, adding any "animal oil, or salt;" then to be boiled in melted nitre, and the powder separated by solution. The powder was found to contain no animal oil or salt, but an animal earth, which, though it may be now called a salt, had scarcely that appellation in Dr. James's time. He adds, that thirty grains of the powder, with one grain of mercury, was a moderate dose; but ten grains of the present powder, without the mercurial is now such. Dr. Pearson, has, however, in the *Philosophical Transactions*, taught us its real nature, and it is nearly imitated in the pulvis antimonialis of the London Dispensatory. This preparation is, however, more active on the stomach and bowels than the powder of James.

Dr. Monro asserts, that Dr. James trusted to the bark in the cure of fevers rather than to his antimonial, which he only employed to clear the first passages. On this we can only remark, that had he really done so we should have heard little of his success.

JANAMU'NDA. See CARYOPHYLLATA.

JA'NIPHA. See CASSADA.

JA'NITOR, (from *janua, a gate*). See PYLORUS.

JA'NITRIX, (from the same). See PORTE VENA.

JA'RUS. See ANUM.

JASMINOIDES, (from the Arabian word *jamen*, and *ειδος, likeness*). See COFFEA.

JA'SMINUM, and *jásminum officinale* Lin. Sp. Pl. 9, is chiefly used for the stimulating power of its essential oil.

JA'TROHPA. See CATAPUTIA MINOR, and CASSADA.

JATRO'PHA ELA'STICA. See CAOUTCHOUC.

JECORA'RIA, (from *jecus, the liver*; from its supposed efficacy in diseases of the liver); the *hepatica vulgaris*; and the name of a vein in the right hand. See SPLENITIS.

JE'CUR, (from the Hebrew term *jaker*). The LIVER; called also *hepar*, the upper part *erix*. Immediately below the diaphragm, on the right side, is placed the liver, whose small lobe extends to the scrobiculus cordis. It is divided into two lobes, besides the *lobulus Spigelii*, which Hippocrates calls *hypercoryphosco*; terminated by an obtuse margin above and behind, and an acute one before and below. The large lobe is situated on the right hypochondrium, contiguous to the diaphragm, reaching nearly as far back as the spine, and rests upon the right kidney: the small lobe runs close to the diaphragm, as far as the spleen. The convex side of the liver is usually connected to the diaphragm by three ligaments, which are continuations of the peritonæum; one lies near the edge of the extremity of each lobe, and one in the middle, and they are accordingly called the right, and left, and middle ligaments. The liver is likewise connected to the right ala of the tendinous part of the diaphragm by a broad adhesion, which is the reflection of the peritonæum, and is called the *coronarium ligamentum*. Under the great lobe, a little to the right, is the gall bladder. The smaller lobe of the liver is in the left side, distinguished above by a membranous ligament, and below by a large division in the same direction as the superior ligament.

The eminences on the concave side of the liver belong to the great lobe; the principal one is a triangular mass, situated backwards near the great division, named *lobulus Spigelii*; this lobe is attached by a little peduncle to the middle of the lower side of the great lobe. The first fissure we observe, next to the great one, is a notch at the anterior part of the liver, for the reception of the ligamentary remains of the vena umbilicalis; the second fissure is towards the posterior part of the liver, between the lobulus Spigelii and the little lobe, where we observe the remains of the ductus venosus, which is afterwards inserted into the vena cava (see FÆTUS). Upon the right of the lobulus Spigelii, between that and the great lobe, is another fissure, in which the vena cava runs down; and the next is a transverse one, situated before the lobulus Spigelii, called *porta*: besides these, on the fore part of the great lobe there is a depression for the reception of the gall bladder; and we may observe on the under side of the great lobe a small cavity, where it rests on the right kidney.

From behind the pancreas a mass of vessels and nerves run up to the porta. The hepatic artery comes off from the cœliaca, and divides into two branches, one of which goes to each lobe; and the vena portæ, when it arrives at the porta, likewise divides into two, one of which enters the right, and the other the left, lobe. From the duodenum and pancreas we see the *pori biliarii*, and ductus communis choledochus, which, at a distance from the porta, divides into two ducts, viz. the cystic, which goes to the gall bladder, and the hepatic, which again is subdivided into two, and go to their respective lobes. The vena cava, in its passage through the diaphragm, sends off several branches, especially two which go to the liver, and are called *vena cavæ hepaticæ*; their office is to return the blood to the vena cava after the bile is secreted. The blood from all the viscera, except the external hæmorrhoidal vessels, is returned to the vena portæ, which ramifies through the liver like an artery. The lower part of this vessel is called *vena portæ mesenterica*; and the upper *hepatica*. The greatest part of these vessels are inclosed in a membranous sheath, called, from Glisson, *capsula Glissonii*. This author first described it as composed of cellular membranes and nerves, covered by the peritonæum at their entrance, and ramifying through the liver with them; but the peritonæum must be absolutely excluded, for the nerves, with their cellular membrane only, go through the liver. The absorbents are very numerous. The nerves arise from the intercostal and eighth pair, which come from the hepatic plexus, and enter this viscus with the vessels.

The external surface of the liver is smooth, and covered with the peritonæum, which is connected with the liver by the cellular membrane, and by the vessels which are spread upon it. The liver is very soft, and like a piece of congealed blood; for it derives its principal consistence from the vessels. Malpighi, after injection, found it to be a congeries of folliculi, in which the vessels terminate. Ruysch thought it a congeries of vessels only in the tenderest part. The *penicilli* of Ruysch are a collection of vessels upon the surface; and, according to this author, the vessels do not terminate in the penicilli, but become infinitely finer; whence the structure of this viscus cannot be such as Malpighi imagined. The liver, according to the ancients, was the

viscus wherein the chyle was converted into blood; but since the knowledge of the lacteals, and the discovery of the circulation of the blood, we know that the use of the liver is to secrete the bile. The blood comes to the liver by the hepatic artery and the vena portarum; but a greater quantity is sent by the latter than by the former, and it is from the latter, as formerly observed, that the bile is secreted. See Winslow's Anatomy, and Haller's Physiology, lecture xxvii.

The substance of the liver is chiefly formed by vessels in the form of small brushes, styled *penicilli*; but it has been doubted whether any follicle is interposed between the vessels of the portæ and the biliary pores. It may be at least asserted, that no such have been demonstrated, and we have no reason to think that any exist.

The bile first appears in minute points, styled *pori biliarii*. These unite and form the hepatic duct, whose coats have no appearance of a muscular structure, but whose internal surface contains numerous, apparently mucous follicles. We omitted to remark in its proper place, that the whole of the blood conveyed by the vena portæ is not employed in the secretion of bile; for the extreme branches of this arterial vein anastomose with the branches of the hepatic vein, and in this way accumulations of blood, when bile is unnecessary, are prevented.

The hepatic duct passes towards, and, descending obliquely, somewhat behind, the pancreas to the lower part of the duodenum. It is inserted, from behind, nearly five inches below the pylorus by a sinus, into which the pancreatic duct also empties itself. This opening is oblique; for the two ducts pass between the cellular coat of the intestine, and again between the nervous and villous coats, before they open into its cavity, and at last are guarded from emptying their contents too rapidly by a convolution of the villous coat. Thus the mixture of the bile is slow and interrupted; for as the duct runs at least an inch between the coats of the intestines, any fulness of the canal must prevent its entrance. At the same time, the convolution of the villous coat, where the duct at last penetrates, must equally hinder fluids from being forced into the duct from the canal.

Near the portæ the hepatic duct receives, at a very acute angle, another from the gall bladder, which, for a little space, seemed to run almost parallel with it. This is called the *cystic duct*; and another from the liver sometimes joins it previous to its union with the hepatic duct. We may just remark in this place, for reasons which will soon appear, that rats, camels, stags, the elephant, the horse, the rhinoceros, the trichechus manati, and the greater number of herbivorous animals, with the dolphin, and many of the cetaceous tribe, have no gall bladder. (Cuvier Leçons de l'Anatomie Comparée, vol. iv. p. 35 and 36.) The idea, however, that the bile is conveyed from the liver to the gall bladder appears improbable, by the retrograde course which it must take to arrive at the latter. To add to the improbability, the cystic duct is smaller than the hepatic, and much smaller than the choledochus formed by the cystic and hepatic ducts. We observe, however, in the other mammalia, that the angle at which the ducts join is neither so acute nor so distant from the gall bladder as in man. In these also the fundus of the vesica is

downward, which facilitates the passage of the bile. In many animals, small canals come immediately from the liver to different parts of the vesica, as in the ox, the sheep, the wolf, the dog, the hedgehog, and the hare (Cuvier, iv. 42); but in man no such canal apparently exists.

Experiments have not been wanting to elucidate this intricate subject. When the common duct is obstructed, both the cystic and hepatic ducts are said to be equally distended: when tied, the result is the same. If the cystic duct be tied, it swells between the ligature and the hepatic duct. Notwithstanding the angle, the bile passes readily, on pressure, into the liver; and in living animals it is seen, when the gall bladder is opened, to distil from the cystic duct. When the cystic duct is tied or obstructed, the gall bladder is not filled, and seems to contain only a serous, or sometimes a mucous, fluid. The vesica biliaris, in its natural state, is not in contact by the stomach; but when this viscus is distended, its greater curvature presses with some force against the gall bladder, and expels its contents.

If we compare these facts, we shall find it highly probable that the vesica is a reservoir for the bile, to keep up a constant supply, when from any accident the exigencies of the system require a larger quantity than the liver can furnish. We have no reason to think that the whole of the bile is sent to the cyst, nor has it been presumed that it gains any different quality. From the necessary absorption, it must become more concentrated, and more bitter and viscid; perhaps more acrid.

We have engaged at a greater length in this question than we should have thought necessary, as in the moment of concluding this article we received the ninety-first number of the Medical and Physical Journal, published in the present month (September, 1806), in which we find Dr. Rush's opinions respecting the use of the liver, &c. He thinks, that, instead of contributing to animalize the fluids recently taken in, the blood requires this circuitous route and this new secretion, to separate the remaining chylous particles which it may contain. The gall bladder, he thinks, as we have already stated, is the reservoir of the superabundant bile, not at the time necessary for the process of digestion; but, he supposes also, that the bile in the gall bladder is farther changed by a putrefactive process, and thus gains its bitter taste. In fact, according to this author, "the gall bladder appears to be to the liver what the colon and rectum are to the stomach," the receptacle only of hepatic fæces. In cases of sickness, indigestion, or long fasting, he adds, in which the office of the stomach is suspended, the liver performs a vicarious duty; and when the functions of the liver are suspended, the stomach, with double anxiety, supplies its place. When the stomach is most busy, the liver is most idle; for the discharge of bile is, in his opinion, obstructed by the fullness of the stomach; and that it is only when the contents of this latter organ have passed the duodenum that the liver "pours its chylè into it." Yet we were before told that the liver was designed to animalize the fluids; and we are immediately afterwards informed, that the same pressure discharges the cystic bile, whose use is to separate the fecal matters from the chyle. It is singular that pressure should stop one fluid, and promote the discharge of another, when their orifices are the same.

We have always declined engaging in controversy, and

can now only add, that, on a careful consideration of the facts and arguments adduced by Dr. Rush, we do not find them applicable to this system, and, of course, they contribute nothing to its support. The facts and experiments which we have collected from different authors, in the present article, seem not to have occurred, to this respectable veteran in the moment of writing, and his system appears neither probable nor consistent.

We own, however, that the consideration of Dr. Rush's system, and the facts which the examination has now led us to review, suggest some doubts whether the bile may not acquire additional properties in the gall bladder. When we reflect that the gall bladder is wanting in herbivorous animals, that it is always found in carnivorous, that the gall of children is sweet, that the hepatic bile is comparatively, if not really, mild and sweet, we are led to suspect that the follicles of cyst may furnish the bitter resinous part of the bile, and that, of course, the gall bladder is a supplementary organ, a glandula succenturiata, subservient to the process of digestion. It is sufficient to state the doubts, with a general view of the facts, which lead to them; but this is neither place nor have we room for more minute discussion. Yet we think we could support this idea from some of the phenomena of digestion, and from some analogous phenomena in the animal machine.

The liver is the seat of various disorders, viz. inflammation, abscess, scirrhus, hydatids, &c. See HEPATITIS; ICTERUS; BILIOSA FEBRIS; CHOLERA MORRUS; HEPATALGIA; and in most of these the countenance is yellow, with a greenish cast. Besides those disorders generally known, Mr. Crawford mentions one, which he denominates an enlargement of the liver. (See his Essay on the Nature of a Disease incident to the Liver.) The principal signs of it are, a great and sudden swelling and hardness of the belly, with a difficulty of breathing; the only very troublesome symptom. Previous to these, a general weakness, a sense of tightness about the breast, and a giddiness of the head on the slightest motion, are perceived; then an œdematous swelling appears in the legs, with pains in the back, thirst, and loss of appetite; the pulse is small and weak, but on bleeding it becomes more full and distinct; the countenance is florid; as the belly enlarges, the breathing is more difficult, and a sense of oppression is then felt about the præcordia; and a stricture about the cartilago ensiformis becomes almost insupportable, soon terminating in a complete suffocation. A violent vertigo and troublesome palpitation of the heart are occasionally observed. Some symptoms of this disorder resemble those of the scurvy; but the sore spongy gums attendant on scurvy are not observed in this complaint.

These symptoms show that an infarction of the liver has, at least, begun, and that it must be quickly obviated. With this view, bleeding, with a mild, nourishing, and somewhat generous diet, has been recommended, followed by active laxatives, with calomel. In a disease where we have no pretensions to experience, we ought not to blame; but unless the symptoms are violent, the bleeding may be, perhaps, dispensed with; or a small quantity only taken. The laxatives are undoubtedly necessary and proper. The formula recommended we add.

R. Aloes socotr. $\frac{z}{3}$ ss. rad. jalap. pulv. $\frac{ʒi}{3}$. calomelan; sap. Venet. $\frac{ʒi}{3}$ ii. bals. Locatel. q. s. ut. f.

massa, ex cuius, singulis drachmis formentur pilulæ N° xii.

The patient is greatly relieved, it is said, a few hours after bleeding; and by means of these pills, repeated at proper intervals, the complaints gradually abate, and the cure is generally completed in the space of nine or ten days.

People who return from warm climates are subject to an increased secretion of bile in the primæ viæ, attended with general languor, nausea, foul tongue, loss of appetite, indigestion, frequently diarrhœa, a yellow skin, with a very unhealthy aspect. Bath waters are in these cases of service, though the Cheltenham spring has lately become more fashionable.

JĒJU'NUM, (from *jejunus*, empty). One of the small intestines, generally found empty: *æcstis*. Where the duodenum ends it begins, and is immediately attached to the mesocolon. It proceeds downwards from the left side to the right, and obliquely forward, making several convolutions, which are chiefly situated in the upper part of the regio umbilicalis.

JĒ'MOU, or **JĒ'MU**. See **GAMBOGIA**.

JESUITA'RUM PU'LVIS. See **CORTEX PERUVIANUS**.

JETAI'BA. The Brazilian name for the locust tree. See **ANIME, GUM**.

JĒ'TICA BRASILIE'NSIBUS. See **BATTATAS HISPANICA**.

JĒTICU'CU. See **MECHOACANA NIGRA**.

JOINTS. (See **ARTICULATIO** and **ARTICULUS**.)

We have resumed the consideration of this subject, to reduce into one view the diseases of the cavities of the joints: these are either effused fluids, or loose cartilaginous or bony bodies. The fluids effused are either blood, pus, synovia, or water. Any fluid is ascertained to exist in these cavities by a swelling felt on every side, and yielding on pressure; while accumulations in the bursæ mucosæ are partial, and will not pass, on pressure, to the opposite side. When the disease arises from a violent bruise, the fluid is probably bloody; the accumulation which follows rheumatism, watery; but when it is the consequence of a strain, which has been followed by violent inflammation, the matter is usually pus mixed with synovia. When discharges, with gradual pressure from a bandage, fail, and the fluid must be evacuated, a very small trochar should be employed; the skin drawn up, so that immediately on emptying the cavity it may be again drawn down, to cover the aperture in the ligament. A sticking plaster must be immediately applied, the joint firmly swathed with a flannel bandage, and some blood taken from the arm to prevent inflammation.

These precautions are peculiarly necessary, as the air stimulates the cavities of joints, and excites an unconquerable inflammation, which nature sometimes relieves by forming an ankylosis, but in which art usually fails.

The extraneous bodies in the capsular ligaments are generally found in the knee; but of the treatment necessary in these cases we have already spoken. See **GENU**.

JO'VIS FLOS. See **CROCUS**.

JO'VIS GLANS. See **JUGLANS**.

JU'BA, a MANE; a panicle, called from its resemblance to a horse's mane.

JUDAICA ARBOR. See **SILICUASTRUM**.

JUDAICUM BITUMEN, (from *Judea*, whence it was brought). See **BITUMEN**.

JUDICATORIA, (from *judico*). A synocha of four days.

JUGALE OS, vel **JUGAMENTUM**, (from *jugum*, a yoke). See **MALARUM OSSA**.

JUGALIS SUTURA. The **SAGITTAL SUTURE**. It is sometimes the suture by which the os jugale is articulated to the bone of the upper jaw.

JU'GLANS, (quasi *Jovis glans*, the nut of Jupiter). The **WALNUT**. The tree is sometimes called *carya*, the appellation of walnuts rendered black by boiling; and the rob *diacaryon*: *nux regia*, *basilica*, *Persica*, et *Euboica*; *caryon*; *caryon basilicon*; *juglans regia* Lin. Sp. Pl. 1415.

The kernel and its oil resemble those of almonds; the shells are astringent: an ointment made by boiling the leaves of walnut tree in lard is said to be an useful application to hæmorrhoids and old ulcers; the bark and the catkins are strong emetics; the juice of the root an active cathartic, and the powdered leaves anthelmintic.

The unripe fruit, which has a bitter astringent taste, is an anthelmintic laxative. Two drachms of the inspissated juice are added to four drachms of cinnamon water, and from twenty to fifty drops given two or three times a day, for six days; interposing a purgative, with calomel, on the fourth. Gargles made of the rob, dissolved in any convenient vehicle, may be used in aphthæ and sore throats. Vinegar, in which walnuts have been pickled, is said to be a very useful gargle.

JUGULAR RES VENÆ, (from *jugulum*, the throat). The **JUGULAR VEINS**; *venæ apoplectica*, and *soporales*. They are external and internal, corresponding with the carotid arteries. The internal, which ascends by the side of the aspera arteria, is called *apoplectica*.

JU'GULUM, (from *jugum*, a yoke; because the yoke is fastened to this part,) the *clavicula* Celsus. The **THROAT**, or anterior part of the neck.

JUJUBA; *zizypha*. The **JUJUBE TREE**; *rhamnus zizyphus* Lin. Sp. Pl. 282. Jujubes are a half dried fruit of the plum kind, about the size and shape of an olive, consisting of a thickish, reddish, yellow skin, a whitish fungous pulp, and a wrinkled stone pointed at both ends. They are the produce of a prickly tree, with three-ribbed leaves, and herbaceous or yellowish flowers, sometimes found wild, but commonly cultivated in the southern parts of Europe.

This fruit is styled incassant and demulcent, and hath been used in pectoral decoctions. The *rhamnus jujuba* has similar virtues.

JU'JUBA I'NDICA. See **LACCA**.

JULA'PIUM; (from the Arabic term *gulab*,) *juleb*, *julepus*; **JULEP**, a form of medicine invented by the Arabians, generally liquid, clear, and sweet; *juleb*, in the Persian language, signifying a sweet potion.

A julep is generally only a vehicle for other articles, to render them more easy in the stomach, or more effectual; so that they should not only be agreeable, but concur with the intention of the principal medicine. This form is often named after the material used, as *Julepum è Camphorâ*, *Cretâ*, and *Moscho*.

JU'LEP. A name for syrupus.

JU'LUS, CATKIN. See **AMENTUM**.

JUNCA'RIA, (from *juncus*, a bulrush). **ITALIAN**

BUSHY HORSE TAIL. Lemery mentions this plant as vulnerary and detersive; but it is not known in the present practice.

JUNCTU'RA, (from *jungo*, to join). See ARTICULATIO.

JUNCUS ODORA'TUS, *fanum vel stramen camelorum, schenanthus, holoschanos, squinanthum, juncus aromaticus, palea de mecha, gramen dactylon aromaticum*; SWEET RUSH, or CAMEL'S HAY; a dried grass brought from Turkey and Arabia, resembling barley straw, and full of a fungous pith; *andropogon schenanthus* Lin. Sp. Pl. 1481: the genus is the same with that which furnishes the spica nardi.

When in perfection its smell is agreeable, warm, bitterish, and not unpleasant to the state. An extract possesses its chief virtues; but other more valuable articles supersede its use. It has been employed as a cordial and an emmenagogue.

- JUNI'PERUS, (from *juvenis*, young, and *pario*, to bring forth; because it produces its young berries while the old ones are ripening). JUNIPER; *juniperus communis* Lin. Sp. Pl. 1470; also called *arceuthos*, and its berry *acatalis*. With us it is a bush, but in Norway a large evergreen tree, the wood of which is called *cedrinum lignum; lignum juniperinum*. Its leaves are slender, narrow, stiff, and sharp pointed; the flowers catkins; the berries have each three oblong irregular seeds; its young fungi are called *calieta*, or *caliette*.

The berries are chiefly brought to us from Holland or from Italy. They should be chosen fresh, not much shrivelled, and free from mouldiness. They have a moderately strong, but not disagreeable, smell; a warm pungent sweetish taste, which, if previously bruised, is followed by a considerable bitterness. The sweetness seems to reside in the juice, or pulpy part of the berry; the pungency in the bark; the bitterness in the seeds; and the aromatic flavour in the oily vesicles spread throughout the pulp and the seeds. In the dried berries this oil is hardened into a resinous substance, visible on breaking the seeds, which are called *ebel*. They give out nearly all their virtue both to water and to spirit. Distilled with water they yield a yellowish essential oil, *alchitron*, resembling, in its medical virtues, that of turpentine, and are carminative, stomachic, detergent, and diuretic.

The London college orders the spiritus juniperi comp. COMPOUND SPIRIT OF JUNIPER, formerly called *aq. juniperi composita*, to be made by adding to a gallon of proof spirit, with as much water as is sufficient to prevent empyreuma, one pound of juniper berries, bruised; caraway and fennel seeds, bruised, of each one ounce and a half; from this a gallon is to be distilled. Pharm. Lond. 1788.

The coriander seeds answer the purpose of the other aromatics; but half a pound is required to a pound of the berries. The common spirit, called *gin*, is flavoured by these berries, though often with turpentine. The name is derived from the Italian *giunipero*.

The rob of juniper berries is prepared by boiling juniper berries well bruised in water, and inspissating this, or the decoction after distilling the oil, to the con-

sistence of thick honey. This is so greatly esteemed as to have obtained the name of *theriaca Germanorum*. It may be used in catarrhs, weakness of the stomach and intestines, and difficulty in making water, to which old people are subject. Hoffmann highly recommends it; though generally considered as an inactive preparation.

The following formula was prescribed by Van Swieten: ℞. Rob bacc. juniperi $\frac{3}{4}$ ij. dilue in aq. juniperi simplicis ℥ ij. spiritus juniperi $\frac{3}{4}$ ij. et ad situm sedandam, sps. ætheris nitrosi $\frac{3}{4}$ ss.: m. dosis cochl. ij vel iv. tertia hora. The infusion of the berries, either alone, or mixed with a little gin, is in dropsies a very useful drink. In uterine obstructions, scorbutic affections, and cutaneous diseases, the juniper is said to have been useful; but in the two last complaints the wood and tops have been preferred. The essential oil is an active stimulant, a warm carminative, an useful diuretic, and a deobstruent. Doses from ten drops to thirty.

The wood of the juniper tree is sudorific, and of similar qualities with that of guaiacum and sassafras, but inferior to either.

JUNI'PERI GU'MMI. The resin obtained in warmer climes, particularly in Africa, is semipellucid, and of a pale yellowish colour; it is in small masses, resembling mastich, but larger; the sandaracha of the Arabians and the gum juniper of the shops. From its use it has been called *vernix*, and the powder is employed to prevent ink running on paper, under the name of *pounce*. This resin hath a light agreeable smell, and not much taste. It dissolves in rectified spirits, if violently shaken in them; and in oils both expressed and distilled, but is insoluble in water. See Lewis's and Cullen's *Materia Medica*.

JUNI'PERUS. A name of several species of cedar. See CEDRUS FOLIO CYPRI, and CEDRUS PHÆNICIA.

JUNI'PERUS LY'CIA. See OLIBANUM.

JUNI'PERUS SABI'NA. See SABINA.

JUPICA'NGA. See CHINA OCCIDENTALIS.

JU'PITER. See STANNUM.

JUS, (because in families it was distributed in just proportions). BROTH; *brodium*. Broths made of the lean parts of beef or mutton are very nourishing; in weak worn out constitutions strong broths cannot be digested, and their strength should always be proportioned to the digestive powers.

JUSTI'CIA. See ADHATODA.

JUVA'NTIA, ADJUVA'NTIA, (from *juvo*, and *adjuvo*, to assist). Medicines or aliments that assist, opposed to *lædentia*, such as injure. When the nature of a distemper was doubtful or unknown, the ancients prescribed some innocent medicines which they were well acquainted with, and according as they were serviceable or otherwise, though in a small degree, they formed some judgment of the future method of proceeding. These approximations were technically styled *juvantia* and *lædentia*.

JUVE'NTUS, (from *juvo*, to help, because at this period of life persons began to be useful). See ÆTAS.

JUXTANGI'NA, (from *juxta*, near, and *angina*, a quinsy). A species of quinsy. See PARACYNANCHE.

K.

K A L

KAA'TH. (See TERRA JAPONICA). Even in a very late work, the Dictionary of Natural History, it is said to be the inspissated juice of the barleria hystrix, probably the *b. prionitis* Lin. Sp. Pl. 887, brought to a greater consistence with farina and saw dust.

KABOLO'SSA. See CHINA OCCIDENTALIS.

KA'DAL. This shrub grows in the East Indies, and is probably the *melastoma malabathrica* Lin. Sp. Pl. 559, though greatly resembling in habit the *osbeckia chinensis*. The fruit, when ripe, is eaten, and calicoes are dyed with the juice.

KADA'NAKU. See ALOES HEPATICA.

KĒKU'RIA. See ELEMI.

KĒMPFE'RIA ROTU'NDA. See ZEDOARIA.

KA'HA. See CURCUMA.

KAKA MOU'LLON, KAKA MULLU. An East Indian siliquose tree. The bark is boiled in milk, and is said to cure a diabetes and gonorrhœa. Raii Historia.

KAKA NIA'RA. An East Indian tree, the leaves of which destroy worms. See Raii Historia.

KAKA-TO'DDALI. *Paulina Asiatica* Lin. Sp. Pl. 524. A small shrub growing in Malabar, used in various disorders, from a redundancy of serum. Raii Historia.

KALENZI-KANSJA'VA. See BANGUE.

KA'LI, (Arabic,) *salsola, salicornia, alga marina,* SALT WORT, and SNAIL SEEDED GLASS WORT. *Salsola kali* Lin. Sp. Pl. 322, a plant with spreading, reddish, pretty thick branches; oblong, narrow, pointed, fleshy leaves, like those of horseleek; flowers imperfect in the bosoms of the leaves, followed each by one seed spirally curled, and inclosed in the cup. It is annual, grows wild on the sea coasts in the southern parts of Europe, particularly of the Mediterranean.

The herb is juicy, bitterish, and remarkably saline. The expressed juice, and infusions, or decoctions of the leaves, are said to be powerfully aperient and diuretic, and been much recommended in dropsies; but the kali is principally regarded on account of its yielding copiously the fixed alkaline salt, called *soda*; and it is cultivated about Montpellier: for this purpose it is prepared at Alicant, in Spain, from a different species of kali. Different marine plants contain this salt, and what is made in Scotland and Ireland is called *kelp*. See Woodville's Medical Botany, p. 387, 388.

K A L

From the *quercus marina*, or *fucus vesiculosus, fucus maritimus, alga marina*, SEA OAK, SEA WRACK, or SEA TANG, much alkaline salt is obtained by incineration: the juice of its vesicles, left to putrefy, yields on evaporation a portion of acrid pungent salt.

The plant is a soft slippery one, common on rocks that are left dry at the ebb tide; the leaves resemble those of the oak tree in shape, the stalks running along the middle of the leaves, and terminating by watery bladders, containing either air or a mucilaginous matter. The vesicles begin to fill in March, burst about the end of July, and discharge a viscid matter.

If the putrid juice is applied to the skin, it sinks into it immediately, excites a slight sense of pungency, and deterges like a solution of soap. One of the best applications at the decline of glandular swellings, for perfectly discussing them, is a mixture of the juicy vesicles on the leaves of this plant, gathered in July, with an equal quantity of sea water: they should be kept in a glass vessel for ten or fifteen days, until the liquor becomes of the consistence of thin honey. The parts affected are to be rubbed with the strained liquor two or three times a day, and afterwards washed clean with water.

A cataplasm of the *quercus marina*, made by bruising a quantity of this plant, is applied externally in cases of scrofula, white swellings, and other glandular tumours. Sea-water and oat meal formed into a poultice sometimes supply its place.

The salt here described is, in strict language, the soda or natron, the mineral alkali; but, in general, every alkaline salt has the same title, and the chemical, as well as the medical properties, are the same. Their affinities also differ very little; but as an external application in glandular swellings, the salt from the sea plants is preferred. See ALCALI and CINERES CLAVELLATI.

KA'LI ARSENICA'TUM. ARSENICATED KALI. Let equal quantities of arsenic and purified nitre be powdered and well mixed together, put into a retort, and placed in a sand bath, the heat of which is to be increased gradually, until the vapours cease to issue from the mouth of the vessel. The mass must then be dissolved in four pounds of distilled water, a proper quantity of which must be evaporated, and the residuum set aside to crystallize. Dose, one fifth of a grain three times a day. This is used for the same purpose as the

solutio arsenici. See INTERMITTENS FEBRIS, and CANCER.

KA'LI, vice SAL ABSI'NTIII. See ALCALI, and CINERES CLAVELLATI.

KA'LI ACETA'TUM. See SAL DIURETICUS.

KA'LI PRÆPARA'TUM. See ALOALI.

KA'LI TARTARIZA'TUM. See TARTARUM.

KA'LI PU'RUM, or FIXED VEGETABLE CAUSTIC ALKALI, is prepared by evaporating a gallon of the water of pure kali to dryness, and afterwards melting it by fire. Ph. Lond. 1788. This salt is deliquescent, which renders the application very inconvenient, unless joined with quick lime. See CAUSTICUM COMMUNE FORTIUS.

KA'LI SULPHURA'TUM. *Hepar sulphuris*. Take flowers of sulphur one ounce, kali five ounces; mix the salt with the sulphur melted by a slow fire, by constant stirring, till they perfectly unite. Ph. Lond. 1788. The dose is from five grains to a scruple. In tetter and other cutaneous affections this salt has been recommended. It has been employed, dissolved in water, as a bath for the psora: and in cases of tinea capitis it has often been used by way of lotion, and has been strongly recommended to prevent the effects of mineral poisons. For the alkaline neutrals see CHEMIA.

KA'LI A'QUA is the kali which has deliquesced in a moist place; and it does not differ from the kali præparatum.

KA'LI PU'RI A'QUA. Take of kali four pounds; quick lime six pounds; distilled water four gallons; add to the lime four quarts of water, and let them stand for an hour; then add the kali, and remaining part of the water; boil them for a quarter of an hour; let the liquor cool, and strain it: a pint of this fluid ought to weigh sixteen ounces. If the liquor raises an effervescence by the addition of any acid, more lime must be added. An earthen or glass vessel should be used, and the liquor strained through linen. Pharm. Lond. 1788.

KA'MSIN. The hot winds blowing over the burning sands of the desert, and reaching Egypt about the period of the equinox. The fatal effects of this wind are in part owing to its containing a considerable proportion of inflammable air, probably from the decomposed water, and in part from its great heat and dryness. The effects of the Samiel of the Desert, a wind nearly resembling the kamsin, is described with great pathos and eloquence by Bruce. See Volney's and Bruce's Travels.

KANE'LLI. A name of two East Indian evergreen trees, the flowers of which are used in diarrhœas; but they are not found in the systems of the botanists. See Raii Historia.

KANNAGHO'RAKA. See CARCAPULI LINCO-TANI.

KAOLIN. One of the ingredients of the Chinese porcelain, probably a growan clay, or a decomposed granite.

KA'PA MA'TA. See ACAJAIBA.

KA'RATAS. The PENGUIN, or wild ANANAS; common in the West Indies, as an acid in punch, but too austere to be swallowed alone. The karatas of Plumier is, however, a different species from the *pinguen* of Dillenius. Each, however, is a species of *bromalia*, and each an American plant. See Lin. Sp. Pl. 408.

KARE'MYLE. See OROBUS.

KA'RFE, (*karfeh*, Arab). See CINNAMOMUM.

KARIN-TA'GERA. An evergreen tree in Malabar; it resembles an hazel. The oil from the root prevents the hair from falling off. Raii Historia.

KARI-VE'TTI. A tree in Malabar; the juice of its leaves is emetic. Raii Historia.

KA'RVA, (*karvah*, Arab). See CASSIA LIGNEA.

KA'TKIN. See AMENTACEI FLORES.

KATO-CŒ'LIA. The ABDOMEN. See CŒLIA.

KELP. MINERAL ALKALI. See KALI, ALKALI, and CHEMISTRY.

KE'NNA. See LIGUSTRUM INDICUM.

KERATOPHY'TON, (from *κερας*, a horn, and *φυλον*, a plant; because it is pellucid). *Lithophyton*. The name of a submarine plant, transparent, of a viscid consistence, and often covered with a cretaceous crust, sometimes of elegant and various colours. The only species which possesses any medical virtue is the CORALLIUM NIGRUM, q. v. and these are very inconsiderable.

KE'RMES, (Arabic term *chermah*). See CHERMES.

KE'RMES MINERALIS. See ANTIMONIUM.

KE'RVA, OL. (*kervah*, Arabic). See CATAPUTIA.

KE'TMIA. The leaves and flowers resemble those of mallows; the fruit is divided into many partitions, the top of which opens when ripe, and discloses many seeds. All the species, except those which taste like sorrel, agree in virtues with mallows. The genus called *ketmia* by Tournefort, is the *hibiscus* of Linnæus. It is of little importance to ascertain any species, as none except the ABELMOSCHUS, q. v. has any medicinal quality.

KE'TRAN. See CEDRIA.

KEYSE'RI PI'LULÆ. KEYSER'S PILLS, (from the inventor's name). According to an account in the Edinburgh Medical Commentaries, they consist of pure quicksilver, reduced to a red calx by a proper degree of heat, which, being dissolved in eight parts of vinegar, is to be mixed with manna, of which two pounds will be required to each pint of the solution. This composition being dried gently by the fire, is rolled into pills, and recommended as the most effectual remedy of all the mercurial preparations against the venereal disease. See ARGENTUM VIVUM.

Mr. Keyser adds a singular remark; if to the solution of a pound of the red calx, in eight pints of vinegar, two pounds of mercury, in the metallic state, be added, a substance will arise, by agitation, to the surface, in the form of cream. If this be taken off, more will rise on every successive agitation. This cream, united with manna, he supposes to be highly useful in recent venereal complaints.

KIBES. An obsolete name for the heel, and consequently for chilblains, which usually affect the heel. See PERNIO.

KI'K, or KI'KI, (from *kike*, Arabic). See CATAPUTIA.

KIKEKUNEMALO. A gum resin, whose source we are not acquainted with. It has a subacid resinous taste, and has been supposed an useful resolvent, as well as beneficial in nervous diseases.

KILBURN WATERS. A bitter purging water. See AQUÆ MINERALES.

KI'NA-KI'NA, (from the countess of Cinchon). See CORTEX PERUVIANUS.

KI'NA-KI'NA AROMA'TICA. See THURIS CORTEX.
 KI'NKINA EUROPE'A. See GENTIANA.
 KI'NO, (Indian). See GUMMI RUBRUM ASTRIN-
 GENS.
 KIPPAKELE'NGU. See BATTATAS HISPANICA.
 KIRIBU'NNAWELL. See CHINA OCCIDENTALIS.
 KNA'WEL. Ray. Tournefort calls it the *chame-
 linum vulgare folio glabro flosculis plurimis*. GERMAN
 KNOT GRASS. *Scleranthus perennis* Lin. Sp. Pl. 580.
 It is somewhat astringent, but never employed in me-
 dicine.
 KO'LERUS. A dry ulcer.
 KO'LTO. See PLICA POLONICA.

KRAUT SAUER. Pronounced by the English
 SOUR KROUT. See BRASSICA.
 KRIE'BEL KRA'NKHEIT. See RAPHANIA.
 KRI'MNA. See ALPHITA.
 KURU'DU. See CINNAMOMUM.
 KUTU'BUTH. An Arabian name for a water
 spider, an insect perpetually in motion. Hence the
 name hath been transferred to a species of melancholy,
 called by Sennertus *melancholia errabunda*. See LY-
 CANTHROPIA.
 KY'MIA. See CUCURBITA.
 KYNA. See OROPONAX.

L.

L A B

LABA'RIUM, (from *labo*). Looseness of the teeth.

LA'BDANUM. See LADANUM.

LA'BEO, (from *labium, a lip*). See CHILON.

LA'BIA. See PROCESSUS.

LA'BIA, and LA'BIUM, (*απο του λαβειν, quò apprehendimus cibum*). A LIP. The lips, of which the red part is called *prolabium*; the sphincter, *orbicularis labiorum*, are sufficiently known. When the cuticle here called *epithelium* is taken off, the appearance of the parts beneath is villous.

LA'BIUM LEPORI'NUM. The HARE-LIP; *rostrum, labellum*, and *labrum leporinum; lagostoma; lagoncheilos*, consists in a division in the upper lip, from a loss of substance, like that of a hare. The division sometimes resembles the letter M, and is then called the *double hare-lip*. A similar fissure in the under lip is called the *spurious hare-lip*; but this seems never to have occurred.

An operation is required, in which we must first divide all its adhesions internally with a scalpel, and with a straight pair of scissors, or rather with a sharp scalpel, as the scissors bruise the parts, cut off the callous edges, so as to make an angle at its upper part. The operator must then pierce the upper end of the divided part with a silver pin, armed with a steel point, at about one third of an inch from the edge of the wound; bring the point nearly to the bottom of the sore, and raise it again through the surface at the distance of nearly one third of an inch. A thread must be next passed across each end of the pin, to draw the lips of the wound together, and like a figure of eight. Another pin is passed through the middle of the lip in the same way, and a third near the other extremity of the fissure. The wound is secured by thread in the same manner, round each pin, and the steel points, which usually fasten by screws, are taken off. A pledget of digestive over the whole will keep the thread soft.

Mr. Pott observes, that when the hare-lip is double, it sometimes happens that the middle portion contracts, and the bone projects. In this case, the projecting bone must be removed by means of a chisel; the contracted part of the lip then brought down and detained by a bandage. The operation is afterwards performed as in the single hare-lip, suffering each side to be thoroughly healed before the subsequent operation is attempted. The pins should not be moved before the sixth or seventh day, and then the stitches must be first cut, to see that the flesh is securely joined before the pins are

moved. When a part of the bone is cut away, the wound must be healed previous to the operation on the lip. See Le Dran's Operations; Heister's Surgery; Sharp's Operations; Bell's Surgery, vol. iv. p. 149; White's Surgery, p. 269.

LA'BIA PU'DENDI, *cremnoi, labra*, arise from the mons veneris, and extend from the fore part of the pubes, whose symphysis is exactly between them, to within a short distance from the anus. They are more prominent, and thick above than below, composed of skin, cellular membrane, and fat; red within, and outwardly, about the the age of puberty, covered with hair. The angles of the labia, above and below, are called *commissuræ*.

LABIA'LES ARTE'RIÆ, (from *labia, lips*). See MAXILLARIE ARTERIÆ.

LABIA'LES GLANDULÆ. The LABIAL GLANDS. The membrane which covers the inside of the lips is a continuation of that on the cheeks, perforated by many small holes, which answer to the same number of small glands. See Winslow's Anatomy.

LABIA'TUS, (from *labia, a lip*). See FLOS LABIATUS.

LA'BIS, (from *λαμβάνω, to lay hold of*.) Any forceps.

LA'BIUM. See LABIA.

LA'BOUR. See PARTURITIO.

LABRISU'LCIUM, (from *labrum, a lip, and sulcus, a deep sore*). A CHAP IN THE LIP, *cheilocace*; generally attending swollen lips, and common in scrofula. It usually requires the treatment necessary in that disease; but, as a temporary relief, may be rubbed with the oleum ceræ, or with the oleum amygdylarum and spermæti. This also is the name given to the cancerum oris.

LA'BRUM, (*απο του λαβειν, from its power of receiving*). See DEXAMENE.

LABRU'SCA, (from *labrum, a lip*; so called because it grows on the sides of fields). See BRYONIA ALBA.

LABYRI'NTHUS, (*λαβυρινθος*). The LABYRINTH. The second cavity of the ear, *fodina*, lies in the pars petrosa of the temporal bone, which runs forward and inward. It is an oblong body, divided into three parts, called the *vestibulum*, the *cochlea*, and the *semi-circular canals*. The vestibulum (in which the stapes stands) is situated in the middle; the cochlea is the

L A B

anterior, and lies forward and inward; and the semicircular canals, which compose the posterior part, lie backward and outward. The three parts of the labyrinth are lined by a fine periosteum, which spreads over, and shuts the two fenestræ of the tympanum.

LAC, (from *lakak*, to lick up, Arabic). Milk is the secreted fluid destined for the nourishment of the animals arranged by Linnæus in the class of *mammalia*, comprehending also, from this circumstance, the *cetacea*. It is a white, opaque fluid; and, when viewed with a microscope, globules, like those of the blood, appear to swim in it. It is, therefore, most certainly, not an homogeneous fluid, whose parts are chemically united, but an heterogeneous one simply mixed. Its resemblance to the blood is striking; and as it is of the colour of the chyle from which the blood is formed, it was an obvious suggestion that the milk was only chyle again separated from the general mass. Chyle has not, however, been sufficiently analyzed to support or confute this idea. It appears, on the whole, improbable, since sugar contains a saccharine matter, and particularly a larger proportion of phosphorated lime than any of the other animal fluids. To which may be added, that milk requires the digestive process as well as other nourishment; and it is never apparently assimilated until it has been coagulated.

Milk was probably the food of the earliest inhabitants of the globe, since their herds, of which their riches consisted, must have afforded an obvious supply of this delicious nourishment. Cheese seems to have been known more early than butter, for it was of importance to preserve a supply of food when the milk of the herds would, at least lessen, if not disappear. Butter is obscurely hinted at by Herodotus, but described more particularly by Hippocrates: each author speaks of the art of making it as being derived from the Scythians. When first drawn, milk has a faint smell, generally mixed with that of the animal which afforded it. This aroma is soon lost on exposure to the air, and much of the delicacy, perhaps the salubrity, of the fluid, seems to disappear with it. The sweetishness, however, remains, but is in different degrees in different animals, depending on the proportion of sugar which it contains. The sweetest milk is that of the sheep.

When milk is at rest, first the aroma disappears, and soon afterwards the surface assumes a yellower colour, and a thick tenaceous scum called *cream* rises to the top. When this is separated, the milk is of a bluish white colour; and, on standing longer, the *curd* or cheesy part separates. An oily substance forms a portion of the milk when first drawn; but the consistence of cream is owing to its imbibing a portion of oxygen from the air; and the curd does not spontaneously separate till the acid fermentation begins. It is separated, artificially, by a variety of substances, as all the acids, except the carbonic, and the weaker kinds similar to it; by different vegetables, as the galium, the vallantia cruciata, the madder, the bark, and, apparently, other vegetable astringents; by some animal substances, as the stomach of a young animal, however carefully washed and dried, the livers of turkeys (Spallanzani), &c. Jacquin, in his Elements of Chemistry, tells us, that the vegetables only act when cold, or in cold infusions. When boiled in milk, or boiling decoctions of the same plants are added, coagulation is retarded

rather than hastened. Milk is coagulated also by salts, particularly such as contain an excess of acid, as the cream of tartar; benzoic and succinic salts; by metallic solutions; by alcohol, and all spirituous liquors; though the addition of camphor or borated soda will, it is said, prevent this effect when either is dissolved in alcohol. In every instance, however, the coagulation is firmer and more perfect with the assistance of heat.

The alkalis which are said to coagulate milk unite in reality with the oily part, and produce a soap, which seems to entangle, occasionally, some of the curd. These flocculi, for such is their form, become successively, by boiling, yellow and brown. Pure alkalis render the milk more fluid, by equally dissolving the oil and the curd. Lime water seems to procure an imperfect coagulation.

Milk, when urged by heat, gives up its oily portion, which forms a dense pellicle; and that part of it which touches the sides of the heated vessel burns, and gives the whole an empyreumatic taste. If this is prevented, the serum procured is thin and pure. If, however, the heat is more violent, an insipid water comes over, flavoured with the aroma of the milk, which soon becomes putrid. The remainder is an extract, which, with warm water, again becomes milk, though without the aroma. If this extract be exposed to a strong heat, an empyreumatic acid oil, ammonia, hydrogenous and carbonic acid gases come over. The remaining coal affords kali, muriated kali, phosphat. of lime, and occasionally a little iron.

When left untouched, milk undergoes the acetous fermentation at different periods, according to the heat of the weather and the nature of the animal. In warm weather, and in ruminating animals, this change is soonest observed. Mare's milk continues longest unaltered. The tendency of milk to the acetous fermentation is checked, it is said, by boiling.

If milk in a moderately warm place be frequently stirred, no separation occurs, and the vinous fermentation comes on. The greatest quantity of spirit, it is said, will be afforded by cow's milk, though that of the mare, as the most saccharine fluid, ferments soonest; and the Tartars prefer it, as affording also more spirit. The putrefactive process comes on slowly. Stupriaan (Memoires de la Societ  de M decine a Paris, 1787-8) informs us, that cow's milk showed no signs of putridity after four summer months, asses milk three months, and female milk nearly an equal time.

The cream, we have said, is the oil, which has acquired a greater consistency by its union with oxygen. In the form of butter it is still more intimately united with this principle, and a chemical union apparently takes place as heat is excited. In general, the cream is suffered to rise spontaneously, but in the West its separation is assisted by heat. The milk is put in shallow earthen pans, and remains in them twelve hours in summer, and twenty-four in winter. The pans are then placed on hot stoves, and the temperature raised, so as to be scarcely short of boiling. On the first appearance of bubbles the pans are removed, and remain at rest twelve or twenty-four hours longer, according to the season. This cream, styled *scalded* or *clotted*, is generally agitated by the hand in making butter, and the churn is only used when the raw cream is employed.

The thickest and richest creams are afforded by the sheep and goat; the milk of the mare, the ass, and the female, afford the thinnest. From female milk scarcely any separation takes place, even with the assistance of heat. The fluid separated in making butter is called *buttermilk*. It is the serum, enriched with some of the oil of the cream.

The curd is a true albuminous substance, without smell or taste, nearly insoluble in water, hardened in hot water, soluble in acids, forming, with the vitriolic and marine, brown solutions; with the nitrous a yellow. It is easily dissolved by alkalis, but most powerfully by the mineral; and, when this is pure, during the solution, a volatile alkaline smell arises; a fact not sufficiently noticed, and which will admit of some application. In distillation, an insipid water comes over that easily putrefies; and the remainder, on increasing the heat, blisters, like burnt horn, affording hydrogenous and carbonic acid gas, ammonia, a heavy fetid empyreumatic oil. The coal contains lime and phosphat of lime. When exposed to a strong heat, in an open fire, curd softens and melts; becomes transparent and tough; and, when cold, is hard and brittle.

The curd of goat and cow's milk is solid and elastic; that of the ass's and mare's milk less solid; of the sheep merely glutinous; of the female generally fluid, and with difficulty separated. See *CASEUS*.

The whey is similar to the serum of the blood. The whey separated in making cheese is a watery fluid, without any admixture of oil; but, in its usual state, some of the oily, and some of the albuminous portion are diffused through it. Sweet whey affords sugar of milk: when the milk has been previously sour, it is styled sour whey; and, by adding a small portion of spirit of wine, and subjecting it to a fresh fermentation, a true vinegar of milk may be prepared (Jacquin). The spirit of milk is apparently not developed till it becomes acid; the Tartars hasten the acetous fermentation by the addition of oatmeal, and do not distil it till it is strongly sour. Thus milk holds a middle place between animal and vegetable substances. As it undergoes the acetous and vinous fermentations, and becomes very slowly putrid, it resembles vegetables. Its albuminous curd is of an animal nature.

Before we proceed to consider the medical properties of milk, we shall describe more particularly the milk of different animals, viz. that of the cow, the human female, the ass, the goat, the sheep, and the mare.

The general appearance of *cow's milk* is well known, and to this standard we shall refer the taste and more obvious properties of other milks. It is differently flavoured, however, according to the age and the food of the animal. When near the time of calving, it is more of an animal nature than at a future period; and the milk of farrow cows is, at first, saline. The alliaceous and the umbelliferous plants, horse mint, cabbages, and turnips, give it their peculiar flavour. The leaves of maize are said to render it mild and saccharine; the potatoe plant insipid. The Alderney, Alpine, and Sardinian cows give a very rich milk: those of the north and of Catalonia an aqueous blue milk. Tessier observed some milk, which was white when drawn, soon became blue; a change attributed to their eating the *isatis* (woad). Dr. Garden found, that the milk was blue after the cows had eaten of this plant; and it is usually

red when they have eaten madder or the fruit of the cactus *opuntia*. Cow's milk, in an ordinary state, boils at 113°.

The carbonic acid gas, the boracic and oxalic acids, do not coagulate this milk when mixed with it, though Stipriaan observes that the latter, if strewed on it in powder, will have this effect. The curds produced by the other acids, are dissolved again by alkalis. When vinegar is employed for the coagulation, the dissolved curd is of a rose colour. Other re-agents act on it nearly as we have said they do on milk in general. The electric fluid thickens it a little. Its specific gravity is 1028.

Eight pounds of milk afforded, on distillation, eight ounces of a clear fluid, which retained the smell and taste of the animal's food. This fluid became turbid after some time, but again clear in a heat of twenty-eight of Reaumur, while some light filaments were formed. When filtered it became clear and tasteless, leaving nothing after distillation. The residuum after the first distillation was sweet and butyraceous, called by Hoffman *franchipan*; and, when diluted in boiling water, the white milky fluid is called *Hoffman's whey*. When distilled, it affords water, a very fluid yellow oil, an acid, a volatile alkali, a thick black empyreumatic oil, and an inflammable gas. The ashes seem to contain an alkali and a muriated soda.

The first milk after calving (*colostrum*, *frimum*, or *beastings*.) resembles other milk, with the addition of a mucous substance. The specific gravity is 1072. It is yellow, but soon coagulates on the fire, and becomes white. The specific gravity of the second *colostrum* was 1052. It is more difficult to coagulate, and stirring wholly prevents this change. Rennet changes the first *colostrum* to a jelly, and coagulates the second: the first contains more than three times the quantity of butter, and a much larger proportion of albuminous matter. Both *colostrum* become more quickly putrid than other milk, and seem to contain a large proportion of the gluten of the blood.

The cream of cow's milk after standing about three weeks, was covered with a green effervescence, and the under part had a cheesy flavour (Parmentier). The scalded cream acquires this flavour much sooner; and this was the reason for our asserting that some of the curd was probably entangled with it. On distilling this semiputrid cream, the usual results obtained from fat bodies were discovered. (See *ADEPS*.) The milk, last drawn from the cow, has the largest proportion of cream; and the cream, as it rises in succession on the milk, while at rest, decreases in quantity, and deteriorates in quality. Thick milk throws up less cream than that which is thinner, but its quality is better. If the milk is diluted with water, the cream is more copious, but less rich. Previous agitation lessens the proportion of cream; and the proper temperature for its rising most successfully is about 54° of Fahrenheit. Milk in autumn gives more cream than in spring; but it rises soonest in summer.

The butter of cows is usually yellow: if white, its quality is inferior. If the milk has been kept too cool, the butter is pale, with little flavour, and not unctuous or rich. To have butter in perfection, the first drawn milk should be separated, and the first risen cream preferred. Some little acidity must take place previous to

the separation of butter, and this must be produced by the agitation, if not before approaching. The cream should, therefore, be kept for some time previous to the churning. The yellowness of butter is probably owing to the constitution of the animal, but the contact of the air has also some effect, for the internal parts of the mass are whiter than the external. To preserve butter from rancidity, two drachms of sugar, as much nitre, with half an ounce of salt, will be sufficient for sixteen ounces of butter. The rancidity of butter depends, in part, upon its retaining some whey, which holds a caseous matter; for it keeps in proportion to its washing: but, after every care, some of the caseous matter seems to remain, and to this its consistence is owing (Fourcroy). Thus, to melt butter without granulations, we add flour to prevent the cheesy portion falling to the bottom, and keep it in constant agitation.

Skimmed milk still retains a portion of the oil and the cheesy matter, which separate on its becoming acid; it is rich and pleasant. This matter is separated also in pellicles, by boiling. When flakes of cheese are put into a fluid alkali they are dissolved, while a considerable quantity of ammonia is separated, formed by a decomposition of the cheese, and the subsequent union of its hydrogen and azote. The alkaline solution of cheese, when heated, becomes brown, and deposits a portion of animal matter. When this matter, held in solution, is separated by acids, it is black, melts in the fire like thick oil, and, when cold, is greasy; the remaining hydrogen, with the oxygen, forming oil, and, with the alkali, becoming saponaceous. When the cheese is separated from the alkali by an acid, an hepatic odour is perceived. The caseous matter is completely dissolved by vinegar, and has a greater affinity to the vegetable acids than to any other.

Whey, when fresh, is sweetish and somewhat saline; but when filtrated, pellucid. It contains some caseous matter dissolved by an acid, which is separated on the addition of an alkali, and a small portion of sugar of milk.

The milk of women is thin, of a bluish colour, of a mild sweet taste, and a pleasant odour. Its specific gravity is 1029. On exposure to air, it is covered with a very thick white matter; but, from this, no butter could be procured. On standing, the portion which separated was still more butyraceous, though still incapable of forming butter. When distilled, water, a strong empyreumatic oil, ammonia, an acid, and inflammable gas, came over. The fluid, then, which was deposited from this unctuous matter, was a butter milk; but its transparency was not changed by alcohol or acids. After evaporation, it afforded sugar of milk, with some cheese. Female milk, when skimmed, did not, in a warm temperature, coagulate in five days; but became turbid and acid. Crystals of sugar of milk were formed, and the thick mother ley afforded muriat of soda. Pellicles rose on heating, as on cow's milk. *Human milk is coagulated as cow's milk, except by acids.* These, even with the assistance of heat, had no effect. It was also not coagulated by alkalis, but the kali gave it a brown, a red, and at last a black, colour; lime water, a deep yellow. The earths, the neutral and metallic salts, alcohol, or the electric fluid, produced no change except on the colour; but the infusion of oak bark and sour milk, previously coagulated, produced a

coagulum. The cheese which it affords is finer and more tender than that of any other milk, but does not form a mass. Sixteen hundred parts of this milk afforded 137 of cream; forty-eight of a matter resembling butter; forty-three of cheese, and 117 of sugar. Three hundred parts of this sugar afforded eighty-five of lactic acid. Human milk scarcely becomes sour after a long period. It never passes either to the vinous or putrid fermentations.

Human milk differs so essentially in different women, and even in the same woman, at different times, that the results of experiments greatly vary. Parmentier found the results so contradictory, that he suspected some deceit, and employed only milk which he drew himself. The results of his trials were, however, still contradictory. This may, perhaps, account for Dr. Clark's assertion, that human milk contains no caseous part, and he could not succeed in coagulating it, by any means, or in any temperature. (Transactions of the Royal Irish Academy for 1788.) What has been supposed, therefore, to be a coagulum of the caseous part, may have been only cream; and during the period of the first and second colostrum only was it found yellow. At every other time it is white.

The milk of the ass is whitish, with some degree of transparency, of a peculiar smell, and a saltish taste, mixed with its sweetness. Its specific gravity is 1023. Alcohol, the metallic salts, rennets, and all the acids, except the fluor, and the cream of tartar when cold, coagulate it. Alkalis produce a slight coagulation, and different changes of colour. Neutrals render it thinner. It coagulates with difficulty when at rest, and the coagulum is weak. The cream is of a yellowish white, sweet, and at first thin. Afterwards it acquires a greater consistence. The whey is sweetish and yellowish. Sixteen hundred parts of this milk afford forty-seven of cream; fifty-three of cheese; seventy-two of sugar of milk, which contains about one fourth of acid. The coagulum of this milk does not depend on its caseous matter, for this is spontaneously separated, falling to the bottom in the form of very tenacious particles. The cream is neither thick nor copious, and, with difficulty, assumes the form of butter, which is soft and white, without any peculiar taste, but quickly becoming rancid. The butter milk, which has a mild pleasing taste, must be carefully separated, or it soon again dissolves the butter. The sugar is in small proportion, and it contains also a little calcareous muriat, sometimes muriat of soda. It agrees with human milk in being soon converted into whey when the caseous matter is deposited; and in proportion to this deposition the sweetness increases.

The milk of the goat is very white, sweetish, and of an unctuous taste. Its specific gravity is 1036. It is affected by re-agents nearly as asses' milk. The cream is very thick, of a mild agreeable taste, and slowly proceeds to acidity. It easily forms butter, which is white, firm, and consistent; and, from its thickness, is easily converted into a very rich cheese, which is not soon injured by keeping. The butter milk abounds with cheesy matter, which may be separated by acids. The quantity of cheese which this milk affords is its chief characteristic. The curd is so copious that the whey separates with difficulty. The curd is also gelatinous and consistent, while in female or asses' milk it is in

divided particles. The cheese is peculiarly rich and agreeable. The butter is white and rich, but not as from asses' milk in consequence of a mixture of the curd, for none is deposited on melting. On this account it keeps long without spoiling. Sixteen hundred parts of this milk contain 127 of cream; 72 of butter; 146 of cheese; 70 of sugar of milk, of which one fourth is lactic acid. The saccharine matter appears to be less than in female or asses' milk. Its sugar white when the serum spontaneously evaporates. When artificial heat is used it becomes a jelly, and the crystals are coloured. The serum contains a very small proportion of common salt.

The milk of the sheep greatly resembles that of the cow. Its specific gravity is 1035, and it readily runs into the acetous fermentation in summer. When at rest, a thick, rich, sweet, yellowish cream rises in considerable quantities, which affords much butter; but it is oily to the taste, and its consistence is not considerable. It easily becomes rancid if not well washed. Its cheese is rich and viscous, but mild and agreeable. The serum affords a very white sugar. Sixteen hundred parts afford 185 of cream; ninety-three of butter; 246 of cheese; and sixty-seven of sugar, of which one fourth was lactic acid, and as much was obtained from the remaining fluid. All the acids (except the carbonic acid gas), alum, and liver of sulphur, coagulate it. Kali and soda render its colour dark; if caustic, red; ammonia, which also attenuates it, yellow. The neutral salts have no effect on it. The characteristics of this milk are the quantity of cream it furnishes, the quantity and richness of its cheese. The famous Roquefort cheese owes its excellence to the mixture of sheep's curd. *Annales de Chimie*, iv. 31.

The milk of the mare retains the smell of the animal, and it tastes as if water was mixed with it, though its specific gravity is 1045. The mineral acids coagulate it; the phosphoric deprives it of its colour and opacity; the fluor and saccharine acids slightly coagulate it when warm. Lime water precipitates a caseous matter when warm; alcohol renders it slightly curdy; rennet has no effect on it. Mare's milk is remarkable for its fluidity, but it is less so than female's or asses' milk, and more tasteless than either. Parmentier informs us that it easily boils, and is not difficult to coagulate. Its distilled water is nearly inodorous, and its franchipan less copious and unctuous than that of the cow. On a slight heat this milk is covered with pellicles, and the first are the most unctuous. The cream rises soon, is yellowish and clear, but produces no butter. The skimmed milk resembles that of the cow, but the vegetable acids separate slowly the cheese, and in a form resembling that from human milk. The serum afforded a vitriolated lime in needle like crystals, and sugar of milk in the form of a saline concretion. The mother water was found to contain muriat of lime. Sixteen hundred parts afforded only thirteen of cream; twenty-six of cheese; 140 of sugar of milk, of which about forty were lactic acid. From mare's milk the ardent spirit is chiefly procured. The art of making it is of great antiquity, and consists in not permitting the separation of the component parts of the milk, or again uniting them, if separated, till an acidity is observed. The spirit is apparently developed at the same time with the acid.

It is remarked by Parmentier, that when cows are

diseased, the albuminous curd is the only part changed. The corresponding part of other animal fluids seems, alone, to suffer from a morbid state of the body.

Stipriaan gives a short comparison of different milks, which we shall subjoin. The most *aqueous*, he observes, is the milk of the ass. Then follows that of the mare, the human female, the cow, the goat, and the sheep. *Cream* was most abundant in sheep's milk; next in the human, the goat's, cow's, ass's, and mare's milk. *Butter* was in the largest proportion in sheep's milk, next the goat's, cow's, and human milk. *Cheese* abounded most in sheep's, then successively in goat's, cow's, ass's, human, and mare's milk. Most *sugar* was afforded by mare's milk, followed by the human, the ass's, the goat's, the sheep's, and the cow's milk. Parmentier divides milks into two classes, the serous and the caseous, or butyraceous. The first contains asses, mares, and human; the second, the cow's, the goat's, and the sheep's milks.

These facts, which have not been hitherto collected in any medical work, point out the absurdity of numerous directions, which fill the volumes of dietetic writers, and those authors who have written on the diseases of children. Women's milk, as we have said, is so various, that general rules can scarcely be drawn; but if any fact respecting it is better established than another, it is, that acids will not coagulate it. We have already observed, that milk must be coagulated before it can become subject to the digestive powers, and this is consonant to another fact, noticed in the article *DIGESTION*, q. v. that, unless the food or drink is delayed in the stomach, though absorbed, it is soon again carried to the excretory organs, as a substance foreign from the habit. This is even the case with water. That milk must be coagulated in the stomach is proved, not only by these circumstances, but by infants vomiting milk as it is taken in, when any disease occurs in the stomach, and their occasionally vomiting it in a coagulated state, when the discharge has been accidental, or from fulness. We recollect some experiments made, many years since, by Mr. Wilson, though we believe not published, in which, after the most attentive examination, no acid could be detected in the stomach of infants. We now see, that if it had been there it would not have produced coagulation. Acid, we know, does occasionally abound in the stomachs of infants, because we find it changing the colour of the bile; but it is not constantly present, and still less is it necessary to assist the digestive process. To assist in this enquiry, we mentioned the effect of rennet, (the stomach of the calf,) though carefully washed and dried, in coagulating cow's milk, and added a fact from Spallanzani, that the liver of the turkey would produce a similar change. Why may not the stomach of a child, and, in a less degree, that of an adult, occasion the coagulation? But, though this be not granted, we have seen that, when human milk has been once coagulated, the former coagulum is sufficient to produce this change in fresh milk; and this is certainly the most common cause. From these observations, we may, at least, draw one inference, that absorbents are too commonly given to children. Acid in the stomach seldom produces any bad effect. It is carried off like any foreign body, and soon neutralized by the bile. Our predecessors, in practice, used them freely; but by

employing the animal earths, they fortunately did not always exhibit an absorbent, and only threw into the stomach a small quantity of an indigestible powder, which was soon again discharged. Such was the Gascoyne's powder, the pearls, and a great variety of costly and fashionable medicines.

In the directions for a milk diet, equal absurdities prevailed. To prevent coagulation, we are sometimes advised to add aqua ammoniæ or lime water (Motherby, fifth edition). We now know that these produce other changes not salutary, and coagulation appears really necessary. We may, indeed, admit, that the coagulum of cow's milk is sometimes too firm, and, with that view, a small stimulus may be necessary to enable the stomach to conquer it; and, for this purpose, a small portion of rum is sometimes added, and, perhaps, some of the warmer spices may be occasionally substituted with more advantage. But to add a medicine which will *promote*, in order to *prevent* coagulation—to prevent what is essentially necessary to the digestion of the milk, is an accumulation of absurdities without example, except in the work we are now attempting to improve.

Milk, we have seen, holds a middle place between vegetable and animal foods. It is milder than the latter, and more stimulating than the former; but in its effects on the constitution it approaches more nearly to animal than vegetable aliment. (See ALIMENT.) The milks preferred as medicinal are chiefly cow's, ass's, mare's, and female milk. The goat's whey is preferred to its milk.

Cow's milk, we have found a rich nutritious fluid; but, by carefully choosing the kind, the age of the milk, the time of milking, &c. it is thinner and more digestible. In many stomachs it is, however, heavy and indigestible; and the idiosyncrasy of the patient should be considered when it is prescribed. The quantity should, however, be also limited; for, if in excess, it produces great inconvenience from its bulk. Physicians have been so much afraid of its coagulating, that they have not employed a very convenient form of cow's milk, the slight curd produced by rennet. Cow's milk is often prescribed in hectic cases, sometimes in fevers, and in cases where the fluids are supposed to be acrimonious, as in cancers, cutaneous eruptions, and similar complaints. In many of these diseases it is, however, too stimulating, particularly in fevers, occasionally in hectics; and, as it has been observed, in the usual preparatory diet for the inoculated small pox. In these cases it is diluted with water, with decoctions of the farinacea, as in gruel, and with whey. Butter milk and whey have been sometimes substituted.

Ass's milk is, we have seen, a less stimulating fluid, and less nourishing. Its oily matter is in much less proportion, its coagulum weak, and, what is apparently of the greatest consequence, the caseous matter is not entangled with it, but precipitated. The little butter which it contains is readily dissolved in its serum. On these accounts, it appears peculiarly adapted to those states in which every stimulus is highly injurious, as in hectics. In the choice of this milk, there is not, however, sufficient discrimination. If many take the milk of the same animal, convenience, rather than the nature of the disease, determines the time; and the richer fluid of the last milking may be thus brought to the most irritable habit. The age of the foal is also seldom at-

tended to, and the laxative colostrum of the early period may be given to those whose bowels are particularly irritable.

Female milk has been seldom employed, nor are we well aware of its medical effects. It contains a large proportion of cream, and a small one of cheese. Its coagulum is also tender, and it resists the effects of acids in producing this change. It will be, therefore, probably useful in all cases where ass's milk has been recommended; nor can we think it, from the bosom of a healthy young woman, so disgusting a remedy as from the ass. *Mare's milk* has been employed, but of its efficacy we know nothing. From its fluidity, and small portion of caseous matter, we should suppose it to be an useful substitute for ass's or human milk.

The very large proportion of cheese in goat's milk does not seem to render it an eligible aliment for invalids, and we believe the whey is chiefly employed. This must probably prove a salutary beverage in some diseases, and we have heard many instances of its success. From our own experience, however, we know nothing.

The sugar of milk is sometimes separated, but rather for curiosity than use, for it is, we believe, never given medicinally. (See SACCHARUM LACTIS.) In the Paris Pharmacopœia, it is directed to be prepared from the whey of cow's milk, clarified, filtered, and evaporated. Whey is usually prepared by adding an infusion of rennet, and is thin in proportion to the hardness of the coagulum. Cheese whey is peculiarly thin, and merely a saline aqueous fluid. The whey prepared for drinking is an opaque fluid, with a proportion of the oil, and a small quantity of the curd suspended. It is not an easy task to bring it to the most pleasing consistence; and it is said a small portion of alum is employed for this purpose. The proportion, however, is so small, that we have not found it give uneasiness even in the most irritable bowels. Whey is, of course, less nutritious than milk, but is a mild soft demulcent, highly useful in the early stages of fever, in hectics, in coughs, and inflammatory complaints of every kind.

Milk is used as an intermede, or *vehicle*, at least to suspend, if not, in part, to render some medicines more miscible with water. Bark, in powder, is covered very successfully by milk; and with a small proportion of a decoction of liquorice is agreeably disguised. The volatile tincture of guaiacum, and similar preparations, are also very conveniently exhibited in milk.

LAC ACE'TOSUM. See ALCAOL.

LAC ANY'GDALÆ. MILK OF ALMONDS. See EMULSIO.

LAC ASINI'NUM ARTIFICIALE. See ERYNGIUM.

LAC CA'LCEIS. MILK OF LIME; water whitened by a solution of quick lime, which is also in part suspended in it.

LAC SPUMO'SUM. See APHROGALA.

LAC SU'LPHURIS. See SULPHUR PRÆCIPITATUM.

LAC VIRGINA'LE. See BENZOINUM.

LA'CCA, (from the Arabic *lakah*). LAC, or GUM LAC; *ancosa*; is a concrete brittle substance, of dark red colour, brought from the East Indies, incrusting on pieces of sticks, internally divided into cells. It is the gummy resinous substance from two species of ficus, viz. the *f. Indica* and *religiosa* Lin. Sp. Pl. 1514, effused in consequence of the puncture of a species of coccus. The nest in which the insect also is sometimes found adhering to the branches is called *stick lac*. In the cells small red bodies are often observed, which appear to be the young insects. If the stick lac is broken into small pieces, and infused in warm water until it ceases to give any tincture to the liquor, the remainder appears of a transparent, yellowish brown colour, and is called *seed lac*: and on raising the heat so as to melt the seed lac, it rises to the surface, and is formed into what is called *shell lac*. When melted, and cast in cakes, it is styled *lac in tablets*.

The seed and shell lacs being robbed of the colouring animal matter, seem to be of an intermediate nature between that of wax and resin, and to partake of the nature of both. They crumble on chewing, and do not soften or unite again; laid on a hot iron, they inflame, and soon burn. If distilled like wax, they yield an acid spirit, and a butyraceous oil. Alkaline lixivium, and volatile alkaline spirit, dissolve them into a purplish liquor. With the help of heat, they dissolve in rectified spirit of wine. Alum promotes their solution in boiling water. Lac is not used in medicine; but the colouring matters serves as a paint, and the remainder is an ingredient in sealing wax. See Neumann's Chemical Works. Lewis's Materia Medica.

From lac an acid is procured, styled the *laccic acid*. Dr. Anderson, in 1786, received from the interior parts of Hindostan nests of insects, resembling cowry shells, which he found to be the coverings of the females of an undescribed species of coccus. Some of this matter, which resembled bees' wax, was sent to England; and, in 1794, Dr. Pearson, in the Philosophical Transactions, published an analysis of it.

About one quarter of this white lac contains a reddish acid, which tasted saltish, and not sour, though it changes paper, stained with turnsole, to a red colour. When heated, the smell is that of newly baked bread. The properties of this acid are very distinct; but as it has not been employed in medicine, they need not detain us.

LACCO'PEDON. See SCROTUM.

LACERATU'RA, (from *lacer*, to tear). See VULNUS.

LACE'RTULI and LACE'RTUS, (from *lacertus*, an arm). BUNDLES OF FIBRES. In every muscle, long, slender, soft fibres are found, possessed of some elasticity, running parallel with each other, surrounded with a large portion of cellular membrane, and collected into what are called *lacertuli*, in shape like the arm from the elbow to the wrist. These, bound together with a looser, generally adipose, membrane, run into large bundles, divided by cellular stripes, or partitions, and are then called *lacerti*. The *lacerti* running parallel, or inclined, surrounded with a thin cellular

membrane, continuous with the partitions, and separated by a thicker cellular texture from the neighbouring fleshy parts, are considered as one muscle. See BRACHIUM, where the word *lacertus* is used in another sense.

LA'CERUM FORA'MEN, (from *λακίζω*, to tear,) one of the inner foramina in the head, through which the third, fourth, first branch of the fifth, and the sixth pair of nerves pass.

LACERUM is also applied to a leaf whose margin is irregular.

LA'CRYMA, (from *δακρυμα*, a tear). A TEAR; and the gum of a tree, which appears in drops like tears.

LA'CRYMA ABIE'GNA. See TEREBINTHINA.

LA'CRYMA JO'BI, *lithospermum*, *millium arundinaceum*, REED MILLET, JOB'S TEARS. *Coix lachryma Jobi* Lin. Sp. Pl. 1378. The seeds resemble tears; and are said to be lithontriptic, but are little used. Raii Historia.

LACRYMALIA O'SSA, (from *lacryma*, a tear). See UNGUIS OSSA.

LACRYMALIA PU'NETA, are two small orifices at a little distance from the internal angle of the eye, on the edge of the eye lids, which lead to the lacrymal canals and sac.

LACRYMALIS GLA'NDULA. See GLANDULA LACRYMALIS.

LACRYMALIS NE'RVUS. The first branch of the fifth pair of nerves is called the *orbital*; and this is subdivided into three others, the last of which is called the *lacrymal branch*; as it is chiefly dispersed on the lacrymal gland.

LACINIA COROLLÆ, (from *lacinio*, to perforate). Any part into which the border of a monopetalous corolla is cut. It is applied also to monophyllous calices, and a calyx which has two laciniæ is said to be bifid; or to divisions on the borders of leaves; hence called

LACINIA'TI, *jagged*, implying an irregularity in the division and subdivision: laciniæ, according to Linnæus, is the same with a part, segment, or cleft.

LACO'NICUM. See BALNEUM.

LACTA'NTIUM TABES, the hectic of nurses, chiefly from debility. See LACTATIO. It is characterized by every symptom of weakness in the animal and vital functions, to which evening exacerbations and morning sweats succeed, even when there is no peculiar affection of the lungs. Indeed the lungs are apparently never affected, unless there is a constitutional predisposition to phthisis. In this disease, the bark and mineral acids, where no pulmonic affection exists, and Griffith's mixture, with myrrh and steel, when such is suspected, are the best remedies. If decided hectic symptoms come on, the disease must be treated as a true PHTHISIS, q. v.

Weaning is often essentially necessary; but we have in general found it more useful first to try whether lessening the quantity of milk which the child takes will not succeed. Even where hectic symptoms have come on, we have thought moderate suckling rather advantageous than hurtful. Much, however, must depend on the mother's health, on that of the child, and many minute circumstances which it is impossible to detail.

See Fothergill in the Medical Observations, vol. v.; and Walker on the Memoirs of the Medical Society.

LACTA'RIA, (from *lac, milk*). See LACTICINIA.

LACTA'TIO, (from *lacteo, to suckle*). SUCKLING. The child should suck, if possible, during the first month; for the early milk is not only advantageous to the child, but the discharge prevents many inconveniences to the mother. If, however, from extreme debility, a deficiency of milk, or too short nipples, this is impossible, it should be consigned to a healthy young woman, whose milk is nearly of the age of the child.

In general, the health of women during suckling is better than at any other period of their lives. Their appetite is excellent; the sleep they have, sound and refreshing; their spirits free; their temper cheerful. If the nurse fails in any of these respects, suckling will be less beneficial either to herself or infant. If she fails in the greater number, particularly in appetite or sleep, she should decline the office.

When the new born child is to be suckled by the mother, it should be applied to the breast in ten or twelve hours after delivery; for the milk is by this means sooner and more easily supplied; fever and inflammation of the breasts more certainly prevented.

If the mother does not suckle her child, her breasts should be kept warm with flannels, or with a hare skin, to keep up a constant perspiration. If she does suckle, she should carefully cover the breasts when she first opens her bosom, and when the child is taken from it, as the cold air is sensibly felt in that tender organ, the skin quickly corrugated, to which pain, inflammation, and abscesses often succeed.

A wet nurse should be young, of a healthy habit and an active disposition, a mild temper, and whose breasts are well filled with milk. If the milk is good, it is sweetish to the taste, and totally free from saltness: to the eye it appears thin, and of a bluish cast. The regular recurrence of the menses is generally an objection; and it is often a very strong one. The inconveniences arise from the child being slightly disordered at the commencement of the return; and the symptoms of teething are often aggravated by the irritation which these returns produce. The menses are sometimes supposed to be advantageous, and are said to *renew* the milk when it is old; but this is an idea without the slightest foundation.

A hired nurse is generally kept from her husband; but by this restriction the temper is often ruffled, and more injury than advantage is sustained by the infant. If the nurse's child is of the same age with that she suckles, she will not probably be again with child till the period of weaning arrives. If older, the greater is the probability of her being again pregnant, and the separation from her husband more necessary. A child may be safely weaned at seven months, but should not suck more than ten. Changes of nurses should, if possible, be avoided; yet this is rather the caution of experience, perhaps of prejudice, than of reason.

Nurses should eat, at least, one hearty meal of animal food, with a proper quantity of vegetables, every day. Thin broth, or milk, is more proper for their breakfasts and suppers than tea; and if the strength should seem to fail, a draught of good ale may be occasionally allowed; but spirituous liquors should be avoided.

Every mother should, for her own sake, as well as her infant's, attempt to suckle. Yet some constitutions are so peculiarly weak and nervous, that the dread of increasing these complaints is a frequent impediment. It should not, however, at least, hinder the attempt; for weak habits have suckled with advantage even to themselves. If, however, the milk is scanty; if, though copious, it is thin and watery; above all, if the child is restless and uneasy; if it frets and pines; a healthy nurse should be procured. But the experiment should first be made, and the attempt should not be given up unless the child suffers. Let every young mother, however, reflect, that if she cannot give up midnight orgies; if she cannot, when her child, by the most pathetic cries, demands, yield it a genial balmy food, uninjured by fatigue, agitation of mind, or indigestion, let her resign her task, or rather forsake her duty. This she may, in part, compensate; but to destroy the health, the constitution of her infant, by the opposite conduct, must for ever be a thorn in her heart; A CRIME WHICH SHE CANNOT EXPIATE HERE, PERHAPS NEVER.

LA'CTAS, (from *lac, milk*). *Lactat*. Salts produced by the union of the acid of the LACTIC ACID, q. v., with different bases.

LACTEA FE'BRIS, (from *lac, milk*). The MILK FEVER. It is a frequent custom to apply the child only to its mother's breast, when the milk flows freely, on the third or fourth day. A fever is thus, from the irritation of the milk, brought on; but it rarely happens to those who have applied the child early to the breast. Where there is a secretion of milk, its due discharge is as necessary as that of the *lôchia*; and the stoppage of either produces fever. Cold, or any cause of fever on the coming on of the milk, may occasion similar inconveniences.

The more immediate causes are a distention of the vessels of the breasts, readily distinguished by the swelling of the glands in the axilla; and an absorption of milk becomes acrid by stagnation. It is known by a rigor and looseness coming on after the breasts have been inflamed and painful, followed by thirst, headach, and burning heat. If the disorder is not violent, it soon spontaneously vanishes by a copious perspiration.

If the patient is full and robust, blood may be taken from the arm; but this evacuation is rarely required. A young, strong, hungry child should be applied to the breast; and linen cloths, dipped in fresh cool drawn linseed oil, laid over them: the bowels should be emptied by a cooling purge, and the saline mixture, with the usual antimonial preparations, given. These, with a thin cooling diet, will generally remove the disease. If the breasts should suppurate, see ABSCESSUS PECTORIS and MAMMÆ; Kirkland on Child-bed Fevers.

LACTEA VA'SA, *galactophori ductus*, (from *γαλα, milk*, and *φερω, to carry*). The LACTEAL VESSELS. These vessels were not unknown to Erasistratus and Herophilus, and are distinctly mentioned by Galen. It was supposed, very early, that they conveyed the nutriment from the intestines; but, as usually the liver was considered to be the part in which the blood was elaborated, these vessels were said to terminate in that organ. Plates still exist in which they are represented as taking this course; though it had been contradicted by Galen. To Asellius the credit of the discovery has been given, and the exact day fixed, viz. the 23d of June, 1622,

when opening a dog for an experiment of a very different nature: but, in reality, he saw them only as Galen and his predecessors had done; and so far from tracing their course to the thoracic duct, he described them as terminating in the liver. He saw, however, their valves, and conjectured, rather than demonstrated, that they receive their contents by orifices opening into the intestines. It is singular that he had not connected with this discovery the description of the thoracic duct by Eustachius, in 1563, which would at once have cleared up the principal circumstances of this *lesser course* of the lymph or chyle.

Asellius never saw the lacteals in the human body, but supposed their existence from analogy; and it was twelve years afterwards, viz. in 1634, that Veslingius first discovered them, and added, in the year 1649, the revival of the discovery of Eustachius, viz. the existence of the common receptacle of the lacteals and lymphatics, the thoracic duct. Rudbeck, nearly at the same era, without any previous communication, discovered the lymphatics in quadrupeds; and about the year 1654 traced the duct in the human body. About the same time our countryman, Dr. Jolyfe, also discovered the lacteals and lymphatics without any knowledge of Rudbeck's success. As these authors discovered them in man and in quadrupeds, so Bartholine seems first to have seen them in fish.

Thus the existence of an absorbing system was apparently ascertained; and, since that period, gradual additions were made to its extent; but the great questions remained undecided: was the absorbent system of vessels general in every part of the body; and were these newly discovered vessels the only ones destined for this purpose? The answer to the first question would, in part, decide the second; for were they general, they were probably the only absorbents. As the extent of their range was increased, therefore the opinion of their being exclusively absorbents was stronger; but, in 1757, Dr. Monro published, at Berlin, a short dissertation, by which he endeavoured to prove, by a few simple and decisive experiments, that the lymphatics were a general system of absorbents. The honour of the discovery was soon after claimed by Dr. Hunter, and a controversy of some asperity was for a time carried on. The observations which we offered on the discovery of the circulation will apply precisely to the present dispute; nor was it without design that we have called the system of the lacteals the "*lesser course*," comparing it to the lesser circulation through the lungs. In fact, the former discoveries had placed this so much on a level with even a common capacity, that it required not the reach of a giant to grasp it. Dr. Monro had undoubtedly the honour of first bringing it forward in a compact scientific form.

At that time, however, and long since, the question was not decided, whether the lymphatics were exclusively absorbents. It is admitted that red veins *do* perform this office, in the foetal part of the placenta, for instance, and in the corpora cavernosa penis. We cannot, therefore, deny their powers; and as the lymphatic system seems not to be equally extensive in every part, it is still possible that the veins may supply their place. We consequently have left the question apparently at issue in the articles ABSORBENTIA VASA and ABSORPTIO; but have little hesitation in offering

our opinion, that the *lymphatics, except in parts of a peculiar construction, are exclusively absorbents.*

We have thus spoken of the lymphatics and lacteals as the same. In fact, they are the same in structure, in direction, and office. The lymphatics sometimes carry a milky fluid, and the lacteals a serous one; each conveys occasionally blood, dissolved or suspended osseous matter; in short, every thing which nature requires to be removed from the cellular or other cavities of the body.

The lacteals arise from the cavity of the intestines, from beginnings almost imperceptible. The discriminating eye of Lieberkühn, assisted by good glasses, perceived, on examining the villous coat, vesicles like a small egg, which he styled *ampullulæ*. These, he thought, were either the extremities of lacteals, or, at least, the receptacles of the chyle immediately absorbed. Later authors have denied the existence of these vesicles, and thought that the small ovoid receptacles were only convoluted arteries and veins surrounding the nascent lymphatic. From a careful comparison of the descriptions, we think it highly probable that Lieberkühn was deceived, and that these ovoid vesicles are really convoluted vessels. We know that the reputed acini of many glands have been found to be vascular. If also the chyle be absorbed by capillary attraction, we know that the vessel must be very minute, or the cohesion of the fluid very inconsiderable. The chyle is, however, a milky fluid, and most probably, like all such, its molecules possess a greater attraction to each other than those of water. A vesicle, therefore, is not well adapted for absorption, and would rather impede than assist the progress of the chyle, thus opposing a function of importance, which often requires a rapid exertion. It seems more probable that the orifices of the lacteals open into the intestines, and that their mouths are very numerous, actually constituting the villi, from which the internal coat has its name, and that each villus has its artery, vein and nerve. In the usual state the villi are apparently pendulous; but when the minute arteries are excited to action, that they are erected like the fimbriæ of the Fallopian tubes; and that in this way their apertures are contracted, so as to become of a proper diameter to absorb the chyle by capillary attraction.

We must not, however, conclude that anatomists of eminence and character, who have described these *ampullulæ*, were wholly mistaken. They have been seen by Lieberkühn, by Sheldon, and by Cruickshanks; but as it is impossible to inject them, it is doubtful whether the chyle may not impart a white colour to the mass of convoluted arteries; and we rather suspect this may be the case, since, in the moment of the discovery, it seems to have been doubtful whether the supposed orifices were not rather the interstices between the adjoining vesicles. If they were the orifices, our objection lies with additional force, that such vesicles are not adapted for capillary attraction. If, too, these were the beginning of the lacteals, they should be scattered in much greater profusion than they are represented.

When the lacteals arise from the cavity, they run along the intestines in a longitudinal direction, freely anastomosing with each other; but the course of the contents of these vessels is opposite to that of the blood. This longitudinal direction is continued for some way,

and the lacteal then turns towards the mesentery, at an angle more or less acute. This lengthened course is probably designed for some peculiar purpose, probably for the animalization of this newly introduced aliment. The vessel then proceeds to the glands interposed, in which they are lost, and from which similar vessels of larger size, but less numerous, emerge. These are styled glands of the first order, as in their course to the thoracic duct other glands are found. In the whole of their progress, numerous valves are interposed to prevent regurgitation; so that sometimes a lacteal, injected with quicksilver, resembles rather a string of silver beads than a continuous vessel.

In the course of the lacteals to the first order of glands, there are few anastomoses; but before entering the glands they are minutely divided. It sometimes happens also, that a lacteal, when it arrives at a gland, will creep over it without being immersed in it; and, at others, a trunk will pass at a little distance. The former fact we do not remember being noticed in any author; but we have often seen it in injected lacteals. Both circumstances are important, as they show how the body may be occasionally nourished when all the glands are apparently obstructed. This also appears the object of nature, in offering different orders of glands, since it is equally necessary that the body should be nourished, and the new fluid elaborated, so that the vessel which escapes the first order may be immersed in some gland of the second, and one that has passed through the first, may escape the second. The lacteals, however, which come off at the upper portion of the canal, pass through fewer glands than those from the ileon; and in old age many of the glands are obliterated. In the duodenum, perhaps, the more perfect chyle is separated; and in old persons the fluids are so highly animalized, that less precaution is necessary in preparing the new aliment. In the colon, the cœcum, and rectum, no lacteals have been discovered; though from the numerous lymphatic glands in the mesocolon lacteals must be found there. From the glands the lacteals pass on to the thoracic duct, and probably, in their course, anastomose with some of the lymphatics.

For the structure of the lacteals, see Lymphæ ductus, and for the glands, Lymphatic glands. See also Ductus thoracicus; Monro de Venis Lymphaticis Valvulosis; Meckel de Finibus Venarum, &c.; Monro's Three Treatises, and his Observations Anatomical and Physiological; Hewson's Experimental Inquiries, part ii.; Sheldon on the Absorbent System; Cruickshanks' Anatomy of the Absorbent System; Mascagni Vasorum Lymphaticorum Corporis Humani Historia.

The *chylifera vasa* are also called *venæ lactæ* because their valves are disposed as those of the veins are, and because, like them, they convey their contents from smaller to larger tubes.

Dr. Harvey discovered the lymphatics in the year 1616. In 1627, they were published by another author. Uzzalius discovered the lacteals in a dog, running to the mesenteric glands, in the year 1662. See Winslow's Anatomy.

LACTESCENTIA, (from *lactesco*, to become milk). The plants whose juices are milky. See LACTIFERUS.

LACTIC ACID. The lactic acid is found in whey when kept till the acetous fermentation has com-

menced. It was first shown to be a distinct acid by Scheele in the Stockholm Transactions for 1780. This acid will not crystallize; but in the open air deliquesces, and probably differs very little from the acetous. Its affinities are nearly the same. See AFFINITY.

LACTICA. See TYPHOS, and TYPHODES.

LACTICINIA, (from *lac*, milk). *Galactina*, *lactaria*; aliments prepared of milk. See ANIMELLÆ.

LACTIFERI DUCTUS, vel TU'BULI, (from *lac*, milk, and *fero*, to bring). LACTIFEROUS DUCTS or TUBES. The glandular body of the breast consists of a collection of membranous ducts, narrow at their origin, broad in the middle, and contracted again as they approach the papillæ, near which they form a circle of communication. See MAMMÆ.

LACTIFERUS, (from the same). The term, though strictly applicable to plants which abound with milky juices, sometimes comprehends those which discharge white, red, or yellow fluids when wounded. The juices of the *euphorbium*, *papaver*, *asclepias*, *campanula*, and many of the plants in the first division of the class *syngenesia*, afford a white fluid; those of the *chelidonium*, *bocconia*, *sanguinaria*, and *cambogia*, a yellow; of the *rumex sanguineus* a red.

LACTIS FLOS. See APHROGALA.

LACTUCA, (from the milky juice it produces on being wounded). LETTUCE; *maritimum*, *cunuchion*, is a plant with slender but firm stalks, which yield, as well as the leaves, a milky juice. The flower consists of a number of flat flosculi, set in a small scaly cup, followed by short flat seeds, pointed at both ends, and winged with down. It is also the name of some species of chondrilla.

LACTUCA ANGINA; *locusta*, *valeriana campestris inodora major*, *valerianella arvensis præcox humilis semine compresso*, *album olus*, *valeriana locusta* Lin. Sp. Pl. 47, α, LAMB'S LETTUCE, and CORN SALAD.

LACTUCA HORTE'NSIS. *Lactuca sativa* Lin. Sp. Pl. 1118. GARDEN LETTUCE.

LACTUCA MARI'NA. (See FUCUS.) In general lettuces are very slightly nutritious, refrigerant, and diuretic: they should be eaten raw. They are easily digested, but afford very little nourishment. Their milky juices inspissated resembles opium; but as a medicine they are of no importance, though the seeds triturated with water are mucilaginous, and supposed to be useful in ardor urinæ.

LACTUCA VIRO'SA. STRONG SCENTED WILD LETTUCE; *lactuca virosa*-Lin. Sp. Pl. 1119. The upper leaves only of this plant are jagged at the edges. In Britain it is indigenous; found in hedges, and by the sides of ditches; flowers in June; smells strongly of opium; and appears to participate in no small degree of its virtues. The narcotic power, noticed by Haller, resides in its milky juice. It is said to quench thirst, to be gently laxative and diaphoretic, powerfully diuretic, not disordering the stomach; but during its operation plentiful dilution is allowed. Out of twenty-four dropsical patients, twenty-three were cured with this medicine, according to the account of Dr. Colin of Vienna. It is given in the form of an extract, made from the expressed juice, and recommended in small doses; though in dropsies of long continuance, from visceral obstructions, it has been administered to the

quantity of half an ounce a day. This plant is, however, now neglected even in Vienna; Quarin and Plenciz have either spoken of it with faint praise or rejected it wholly. In this country it seems never to have been fairly tried.

LACTUCI'MINA, (from *lacteo*, to suckle; a disease of children while they suck). See APHTHÆ.

LACTU'MEN, (from *lac*, milk; because the eruption is covered with a white scab). See ACHOR.

LACTU'MINA, (from *lac*, milk). Little ulcers or crusty scabs in the skin, chiefly occurring in children at the breast.

LACU'NÆ, are excretory ducts in the vagina and glands, or their excretory ducts in the urethra. The term sometimes implies drain or furrow (from *lacus*, a standing pool).

LA'DA. See PIPER NIGRUM.

LA'DA CHILLI. See PIPER INDICUM.

LA'DANI EMPLA'STRUM. See ENPLASTRUM STOMACHICUM.

LA'DANUM, (from *ladon*, Arabic,) *labdanum*, *cistus*, *cistus ladanifera*, *ledon Cretense*. The TRUE LADANIFEROUS SHRUB. *Cistus ladaniferus* Lin. Sp. Pl. 737, or rather *c. Creticus* Lin. Sp. Pl. 738. The gum labdanum is a resinous juice which exudes upon the leaves of the shrub, which grows plentifully in Arabia, Candia, and other parts of the Archipelago. The juice is collected during the summer with a kind of rake, which hath several leather thongs fixed to it instead of teeth, with which the leaves of the shrub are lightly brushed: the juice adhering to the thongs is separated with knives, and formed into regular masses for exportation. The plant grows on the sea-shore; and much sand is consequently mixed with the gum.

The best sort is in dark coloured black masses, of the consistence of a plaster, which grows still softer when handled: the other is in long rolls curled up, harder than the former, but of a paler colour.

In general, this gum agrees in virtues with the balsam of Peru; but is rarely used except in external applications. It hath an agreeable smell, and a light, pungent, bitterish taste. Rectified spirit of wine dissolves nearly the whole of the pure gum; and water takes up much of its smell and taste. By distillation with water an essential oil arises, leaving behind it a brittle resin.

Heat quickly destroys the specific flavour of this gum, which was formerly given as a pectoral and astringent in catarrhal affections and dysenteries; but is now confined to external use in the form of a plaster (see ENPLASTRUM STOMACHICUM), or in fumigation. See Lewis's *Materia Medica*; Neumann's *Chemistry*.

LÆDE'NTIA, (from *lædo*, to hurt). See JUVANTIA.

LÆ'MOS, (from *λαω*, to feed). See CÆSOPHAGUS.

LA'GAROS. LOOSE. An epithet for the right ventricle of the heart, from its looser texture. See COR.

LAGOCHEI'LOS, (from *λαγος*, a hare, and *χειλος*, a lip). See LABIA LEPORINA.

LA'GON. THE FLANK.

LAGO'NDI. See BERIBERI.

LAGOPHTHA'LMIA, and LAGOPHTHA'L-MUS, (from *λαγος*, a hare, *οφθαλμος*, an eye). See ECTROPIUM.

LAGOPO'DIUM, and LA'GOPUS, (from *λαγος* a hare, and *πυς* a foot,) *hes leporinus*; *trifolium arvense*

humile spicatum; HARE'S FOOT TREFOIL, or TRINITY GRASS; *trifolium arvense* Lin. Sp. Pl. 1083; is a low spreading plant with narrow hairy leaves like a hare's foot; the flowers are of a purple colour; the root perishes in winter. It grows amongst corn, and in fallow fields; flowers in June and July: the whole plant is reckoned astringent; but rarely used.

LA'GOPUS. HARE FOOTED; the name of some species of trifolium. See ATTAGEN.

LAGO'STOMA, (from *λαγος*, and *στομα*, os, the mouth). The HARE LIP. See LABIA LEPORINA.

LA'LO. See BAOBAB and COUSCOUS.

LA'MAC. See GUM ARABICUM.

LAMBDA'ISMUS, (from *λαμβδα*, the Greek letter λ). A defect in speech, consisting in an inability to pronounce certain consonants, particularly L.

LAMBDOI'DES, *proæ sutura*, (from the Greek letter λ, and *ειδος*, likeness). The name of the suture which runs betwixt the ossa occipitis and parietalia, called from its resemblance to the Greek letter λ, lambda. It is also a name of the os hyoides.

LAMELLÆ. LITTLE LAMINÆ.

LA'MINA, (from *ελαμινη*, from *ελαω*, to beat off). A bone, or any substance resembling a thin plate of metal. The lap of the ear.

LA'MINA CRIBRO'SA. The cribriform lamella; the horizontal plate of the os ethmoides, through which the olfactory nerves pass.

LA'MINÆ SPONGIO'SÆ INFERIO'RES. See CONCHÆ NARIUM INFERIORES.

LA'MIUM, (from *lama*, a ditch, where it usually grows). DEAD NETTLE.

LA'MIUM ALBUM, Lin. Sp. Pl. 809, *urtica mortua*, *Archangelica flore albo*, *urtica alba*, *urtica iners*. WHITE ARCHANGEL, or DEAD NETTLE.

LA'MIUM LUTE'UM; *galeopsis galeobdolon* Lin. Sp. Pl. 810, *galeopsis*, *leucas montana*. See GALEOBDOLON. YELLOW ARCHANGEL.

LA'MIUM MACULA'TUM, Lin. Sp. Pl. 809, *galeopsis lutea*, *mizadella*, *urtica lactea*. SPOTTED ARCHANGEL.

LA'MIUM RU'BRRUM, also called *lamium purpureum fetidum*, *galeopsis*; *lamium purpureum* Lin. Sp. Pl. 808. RED ARCHANGEL, or SMALL DEAD NETTLE.

Infusions of these plants are commended in the fluor albus; but experience hath not supported the high character given them by popular report.

LA'MPATAM. See CHINA ORIENTALIS.

LAMPOU'RIS, (from *λαμπω*, to shine). See CINDELA.

LA'MPSANA, (from *λαπαζω*, to evacuate; because it relaxes the bowels,) *napillaris herba*, *napium*, *endivia erecta*, &c. DOG CRESSSES, NIPPLE WORT; is a rough plant, bearing small yellow flosculous flowers; annual; growing wild in fields, and by the sides of the roads. It is one of the bitter lactescent plants, nearly similar in virtues to dandelion and endive. It hath been applied to ulcerations on the nipples, whence one of its names; but the present practice does not notice it. It is also a name of rapistrum.

LA'NA, (from *λανιο*, to tear). WOOL. Burnt wool is escharotic.

LA'NA SU'CCIDA. SORDID or YOAKY (unwashed) WOOL; *aphytos* by the Greeks.

LANA'RIA, (from its woolly leaves). A name of the *lychnis sylvestris*, *saponaria*, and *verbascum*.

LANA'TUS, applied to leaves covered with a downy softness.

LANCET. A well known surgical instrument.

LA'NGUOR, (from *λαγγω*, to pine). WEAKNESS OF MIND AND BODY.

LA'NGUOR PANNO'NICUS. See AMPHIMERINA HUNGARICA.

LANI'GERUS, (from *lana*, wool, and *gero*, to bear,) an epithet of trees, which bear a woolly or downy substance, like what is contained in the catkins of the willow.

LAN'TANA. See VIBURNUM.

LANU'GO, (quasi *lanam ago*, bearing wool). DOWN. The seeds of plants surrounded by a downy substance which carries them in the air are termed *lanuginous*, or *pappous*. See CHNUS.

LACO'NICA CURA'TIO. A method of curing the gout by warm applications.

LA'PARA, (from *λαπαζω*, to empty). THE FLANKS, which seldom appear distended.

LAPAROC'ELE, (from *lapara*, the flanks, and *κηλη*, rupture). A rupture through the side of the belly.

LA'PATHUM, (from *λαπαζω*, to evacuate; because it purges gently). DOCK.

LA'PATHUM ACU'TUM; *rumex*, *oxylapathum*, SHARP POINTED DOCK; *rumex acutus* Lin. Sp. Pl. 478. This species, denominated from its sharp pointed leaves, hath a bitter astringent taste, with no remarkable smell: its roots discover their astringency, both by the taste and by striking an inky blackness with a solution of vitriol; and this astringency is stronger in the present than in any other species. It is also slightly laxative; and its affinity with the rhubarb is equally conspicuous in a botanical and a medical view. Water takes up all their virtue, and in spring they are used with the greatest advantage.

LAPATHUM ALPI'NUM, *hispolapathum rotundifolium*; *lapathum montanum*, BASTARD MONK'S RHUBARB; *rumex alpinus* Lin. Sp. Pl. 480. The leaves are very broad like those of burdock; the root is extremely broad, and intensely red within. It has, however, no peculiar virtue, except that it is supposed to be more active as a laxative than the other species.

LA'PATHUM AQUA'TICUM; *hydrolapathum*, *herba Britannica*, *lapathum palustre*, GREAT WATER DOCK. The hydrolapathum of the Edinburgh Pharmacopœia is referred to the *rumex aquaticus*, *foliis cordatis acutis*, *floribus hermaphroditis*, *valvulis integerrimis nudis* Lin. Sp. Pl. 479. Muntingius has taken great pains to prove this species the *herba britannica* of the ancients; not from Britain, but from *britannicus*, a Teutonic word, which signifies a power to fasten loose teeth. Linnæus, however, gives the preference to a species which he styles "*Britannica*;" but Lobelius, with great reason, supposes it to be a species of cochlearia. The leaves of the *rumex aquaticus* are from two to three feet long, said to be laxative, but are very inconsiderably so: the roots are blackish on the outside; internally white, having a faint reddish tinge, which, in drying, changes in some parts to a yellowish or brown. It is found in most parts of England by river sides; and supposed to be a powerful antiscorbutic, if freely taken internally. A strong decoction of it is supposed to heal spreading ulcers in the mouth and tonsils; to cure spongy gums, &c. Boerhaave, from his own experience, commends

it in scurvy, rheumatism, as well as in disorders of the skin, and from obstructed viscera. It is probably useful in flatulent complaints, and seems occasionally to assist digestion. Linnæus speaks highly of its utility.

The root dried and powdered is said to be antiseptic, useful in nervous disorders, an useful dentifrice, and a good substitute for the bark. Where the powder is unacceptable as an internal medicinè, the decoction may be used: half a pound of the bark of the root is boiled in three to two quarts of water, and half a pint drunk four times a day.

The bark of the root contains the greatest proportion of the active parts; but the whole plant resembles in its medical virtues the root. See Medical Musæum, vol. i. p. 46, &c. It seems, however, to be in no respect superior to other astringents, and inferior to many of this class.

LA'PATHUM HORTENSE; *rhabarbarum monachorum*, *patientia*, *hispolapathum*, MONKS' RHUBARB; *rumex patientia* Lin. Sp. Pl. 476. The stalk of this dock is red, and branched towards the top: the root is thick at the head, but soon divides into several branches of a brown colour outwardly, and a deep yellow within. Its virtues are similar to those of rhubarb, but it is less purgative and more astringent.

LA'PATHUM CHINE'NSE ORIENTA'LE. See RHABARBARUM.

LA'PATHUM RU'BRUM; *lapathum sanguineum*, *sanguis draconis herba*, BLOOD WORT; *rumex sanguineus*. Lin. Sp. Pl. 476: the leaves are recommended as laxative, and the seeds for restraining uterine fluxes.

LA'PATHUM UNCTUOSUM. See MERCURIALIS.

LA'PATHUM VU'LGARE; *anaxyris*; BROAD LEAVED WILD DOCK, OR COMMON DOCK; *rumex obtusifolius* Lin. Sp. Pl. 478. The leaves are large, roundish at the points, and sourish to the taste; the root bitter, astringent, and of a pale or yellowish colour. In France the root is most frequently used, and for the same purposes as the great water dock. The largest grow in moist grounds, the smallest and most astringent in dry.

LAPIDES CANCRORUM. See CANCER.

LAPID'ILLUM, or LAPID'ILLUS, (from *lapis*, a stone). The name of a kind of spoon, formerly used to take out small stones and fragments from the bladder.

LAP'ILLI, (a dim. of *lapis*, a stone). See OCVLI CANCRORUM.

LAPIS, *λαας*. A stone differs from an earth in consistence only; but there are some bodies, evidently stony, which contain no earth, as the diamond. The mineralogists who arranged fossils from their external forms, of course distinguished *stony bodies*, but this arrangement has been superseded by the chemical systems of the moderns; and Wallerius is the last author of credit who has followed it. Stones are defined by that naturalist as hard bodies which cannot be cut with a knife, seldom rasped by a file, brittle, without ductility, insoluble in water or oil; but falling into small particles by exposure to air.

We need not pursue the qualities of stones farther than to mention Wallerius' subdivisions of this class of bodies into *calcareous*, *vitrescible*, *fusible*, and those *unaffected by fire*. The compound stones he styles *rocks*.

It will be obvious from the medical bodies styled "*stones*," which follow, with what little accuracy the

term has been bestowed. It is, however, now disused in a very great degree, and will not be again revived. Wallerii Systema Mineralogicum. See MINERALOGY.

LA'PIS CALAMINARIS. See ZINCUM.

LA'PIS CALCAREUS. See CALX.

LA'PIS ANPELI'TES. CANAL COAL. See AMPELITES.

LA'PIS A'LCHERON. See BEZOAR BOVINUS.

LA'PIS BE'NZAHAN. See BEZOAR FOSSILE.

LA'PIS BEZO'AR, and PERUVIA'NUS. See BEZOAR ORIENTALIS and OCCIDENTALIS.

LA'PIS PORCI'NUS et MALACE'NSIS. See BEZOAR HYS-TRICIS.

LA'PIS SEPTICUS. MELTED KALI.

LA'PIS NEPHRITICUS is a variety of the jaspis, the *jade* of Haüy iv. 368; of the Sciagraphia; and of Kirwan, vol. i. p. 171. It is very hard, but melts in the focus of a mirror, to a transparent glass, with some air bubbles. Its specific gravity is about 3. Its look and touch greasy, and it contains about 0.38 of magnesia. It is celebrated for relieving the pains of gravel, and even of destroying the calculus. It has this effect, it is ridiculously supposed, when hung about the neck. Boot Gemmarum et Lapidum Historia, ii. 110.

LA'PPA, (*απο τῆ λαβειν*, from its sticking to the clothes). See BARDANA MAJOR, MINOR, and ARCTIUM.

LAPPA'GO, (a dim. of *λαππα*). See HIPPOPHÆS; sometimes the aparine. Blanchard.

LA'PPULA CANA'RIA, (from *λαππα burdock*). See CAUCALIS.

LAPSANA COMMUNIS, Lin. Sp. Pl. 1141. DOG CRESSES or NIPPLE WORT. It is cooling, and somewhat astringent, but differing little from the endive or succory. As its name implies, it has been most commonly used as an application to sore nipples.

LAQUE'US, (from the Hebrew term *laquah*). See BROCHOS.

LAQUE'US GU'TTURIS. A malignant inflammation of the tonsils.

LA'RDUM, (from *lar*, a chimney, in which it is dried). BACON. See ALIMENT.

LA'RIX, (*λαρος*, pleasant, from its beautiful appearance). The LARCH TREE; *pinus larix* Lin. Sp. Pl. 1420. The leaves are long and narrow, produced out of small tubercles, but fall in winter; the cones are small and oblong; the branches regular; common on the Alps, and in several parts of Germany: from it is produced the Venice turpentine. Raii Historia. It is also a name for several species of cedar. See CEDRUS.

LA'RVA, (from *lar*, a shadow, or familiar spirit). A MASK. When the face is burnt with gunpowder, &c. the application is a linen mask, moistened with proper remedies, and applied to the face: it is tied behind with six tapes. The appellation also of insects in the form of caterpillars, which is considered as their disguised state, since their perfect form, in which the species will be reproduced, is that of a butterfly.

LARYNGÆ'Æ ARTE'RIÆ, (from *λαρυγξ*, the *larynx*). See GUTTURALIS ARTERIA.

LARYNGOTO'MIA, (from *λαρυγξ*, the throat, and *τομια*, to cut). See TRACHEOTOMIA.

LA'RYNX, (a Greek primitive). See ASPERA ARTERIA.

LASCI'VUS, (from *lacio*, to ensnare). See CHOREA SANCTI VITI.

LA'SER. LASERPITIUM. See ASAFÆTIDA.

LASERPI'TIUM, (from the Arabic *lazar*,) the name of the *oreoselinum*; and of the *silphium*, the *altiit* of the ancients.

LASERPITIUM VULGA'RE; *bupleuron arborescens salicis folio*; *gentiana alba*; *cervicaria nigra et alba*; *Libanotis*; *Thapsia*; *seseli Æthiopicum*; the LESSER HERB FRANKINCENSE; LASERWORT; *laserpitium latifolium* Lin. Sp. Pl. 356; is a plant found in Switzerland, and on the Pyrenean mountains. The root is supposed to be alexipharmic and uterine; the seeds are somewhat acrid. It flowers in August.

LASSITU'DO, (from *lasso*, to weary). MUSCULAR DEBILITY.

LA'TA LIGAME'NTA. The BROAD LIGAMENTS of the womb are properly only a duplicature of the peritonæum, reflecting from the loins to the uterus, and are long enough to admit it to hang down into the vagina.

LA'TER, (from *latus*, broad). A BRICK. Bricks are heated and applied to various parts of the body, or on cataplasms, to continue their heat. An oil is made by quenching hot bricks in olive oil until the whole is imbibed, which is afterwards drawn off. This oil is named *oleum lateritium*, *philosophorum*, *sapientiæ*, *perfecti magisterii*, *divinum*, *benedictum*; but it is now deservedly neglected.

LATERA'LES MUSCULUS, (from *latus*, a side). See MASSETER.

LATERA'LIS MUSCULUS NA'SI. See OBLIQUUS NASI.

LATERA'LES PROCESSUS OSSIS SPHENOIDES. See SPHENOIDES OS.

LATERA'LIA, (from *latus*, a side). LIGAMENTA. On the body of the os humeri there are two particular ligaments, which may be called *lateral* or *intermuscular*: they are long, flat, thin, narrow, fixed on one edge along the two lower thirds of the bone, and reaching to both condyles. They are braced pretty tight, and are very narrow at the upper part, but broader towards the condyles, from whence they are expanded like a goose's foot, and form the brachio cubital and brachio radial ligaments.

LATERI'TIUM OLEUM. See LATER.

LATERI'TIUM SEDIMENTUM. A SEDIMENT IN THE URINE, resembling *brick dust*, observed after the crises of fevers, particularly intermittents; and the most certain mark of a salutary termination of a gouty paroxysm.

LATHY'RIS, (from *λαθω*, to forget, as affecting the memory). See CATAPUTIA MINOR, OCHRUS.

LATI'SSIMUS, *dorsi*, *musculus*, (from *latus*, broad). ANISCALPTOR, because it bends the arm backward. This muscle rises from the fascia lumborum at its lower part; and higher, from the sixth, seventh, or eighth vertebræ. At its anterior part, it rises from the ninth, tenth, eleventh, and twelfth ribs: its fibres run round the posterior and inferior angle of the scapula; and its tendon is inserted into the posterior ridge of the groove of the biceps.

LAUCA'NIA, (from *λανω*, to receive). See CÆSOPHAGUS.

LAU'DANUM, (from *laus*, as worthy of praise,) generally confined to preparations of opium. See OPIUM.

LAURE'OLA FŒ'MINA, (a diminutive of *laurus*, *laurel*; which it resembles,) *mezerion*, *chamælaea*, *thymelæa folio deciduo*, MEZEREON, SPURGE OLIVE, WIDOW WAIL; *Daphne mezereum* Lin. Sp. Pl. 509; is a small tree, or bush, with pale purplish or white flowers, followed by bay shaped leaves; flowers in January; the berries, called *cocci cnidii*, ripen in August and September. This plant, especially when fresh, if retained in the mouth, and chewed a little, is so very acrid as to occasion violent heat and inflammation in the fauces and throat. The berries have the same effects, and when swallowed prove a most destructive poison. The bark and berries have been long applied externally, in different forms, to old and ill conditioned sores. The former is strongly recommended in France as an application to the skin, producing, by proper management, a serous discharge, without blistering, which may be continued as a perpetual blister, with less pain and inconvenience than the cantharides. It has been used as a seton in inflammations of the eyes. The recent bark, about three quarters of an inch broad, and one inch long, after macerating a little time in vinegar, is applied for this purpose to the skin; over which is placed an ivy or plantain leaf; and the application is renewed night and morning till it brings on a serous discharge. A renewal once in twenty-four hours is afterwards sufficient to continue it.

A decoction of the cortical part of the fresh roots is a powerful remedy in many venereal symptoms, especially when assisted by the hydrargyrus muriatus. The best grows in a light soil. An ounce of the fresh gathered bark must be boiled in twelve pints of water to eight; and at the end of the boiling an ounce of liquorice root added: of the strained liquor half a pint may be drunk four times a day. Dr. Russel strongly recommends the use of this decoction, particularly when nocturnal pains are violent in the syphilis; and for washing those nodes which proceed from a thickening of the membrane of the bones. See Lewis's *Materia Medica*; London Medical Observations and Inquiries, vol. iii. p. 189, &c.

It is said to cure the remains of the lues venerea, where mercury has failed. Dr. Cullen and Dr. Home found it not only cure scirrhus tumours, and obstinate ulcers, which remain after the venereal disease, but that it sometimes healed scirrhi from other causes. In cutaneous affections, in chronic rheumatism, and palsy, it has sometimes been successful. In the case of a difficulty of swallowing, thought to be occasioned by a paralytic affection, Dr. Withering directed a thin slice of this root to be chewed as often as the woman could bear it. Though the complaint had been of three years standing, she was relieved within a few weeks.

LAURE'OLA MAS, *chamædaphne*, *eupetalon*, *thymelæa*, *laurifolia semper virens*, *daphnoides*, SPURGE LAUREL, *daphne laureola* Lin. Sp. Pl. 510; is a small shrub: its leaves are less than those of the laurel, and the flowers consist of one leaf, which is greenish, and appear in April; the berries open in September. The leaves, berries, and bark, are highly acrid, burning and inflaming the mouth: if swallowed, they vomit and purge. See Raii *Historia*; Lewis's *Materia Medica*.

Laurifo'lia Magella'nica, (from *laurus*, and *folium*, a leaf; because its leaves resemble those of the laurel.) See WINTERANUS CORTEX.

Lauri'num Oleum, (from *laurus*). See LAURUS VULGARIS.

LAU'RO-CAMPHORI'FERA, (from *laurus camphora*, and *fero*). The CAMPHOR BEARING LAUREL, OF BAY TREE. See CAMPHORA.

LAU'RO-CERA'SUS, (from *laurus*, and *cerasus*, *cherry*; because it bears a cherry, and has leaves like the laurel,) *padus cerasus*, *cerasus avium nigra*, *cerasus racemosa fructu non eduli folio laurina*, or *trapezuntina*. BAY CHERRY, LAUREL CHERRY, OF CHERRY BAY, *frunus lauro cerasus* Lin. Sp. Pl. 778.

The root of this tree or shrub is large, rough, and furnished with many fibres. The branches are woody, numerous, brown on the outside, and white within. The leaves are large, fleshy, oblong, shining, pointed at both ends, and slightly serrated at the edges: their upper surface is smooth, and of a light dark green colour; the under side is of a light green, rough, strongly marked with fibres. The flowers appear towards the superior part of the branches; are pentapetalous, in five leaved cups, followed by clusters of berries resembling cherries, and containing an oblong stone. It flowers in May, and ripens its fruit in September.

The leaves have a bitter taste, with a flavour resembling that of bitter almonds, or the kernels of peaches and apricots, which is communicated to water and alcohol by infusion or distillation. These preparations are so suddenly deleterious, either in the stomach or rectum, or applied to wounds, as sometimes to occasion instant death. Dr. Mead relates, that a few spoonfuls of laurel water killed a large dog before it could be supposed to have reached the stomach; and it acts by destroying the mobility of the nervous power without exciting inflammation, or producing any sensible change in the state of the fluids. Like all other powerful sedatives, it produces violent spasmodic motions of the whole body; though, when in a concentrated state, it is often immediately fatal without such previous symptoms.

As it evidently lessens or destroys the irritability of the nervous system, increasing at the same time, according to Wurtzer, the action, he thinks it useful in great nervous irritability, particularly where from this cause the heart is affected with palpitations.

On dissection, no uncommon appearances are observed in the stomach or intestines; the arteries are found empty, and the veins turgid with blood. The sinuses of the brain, and the veins of the pia mater, are distended; the effect rather of the convulsions than the particular properties of the poison. Less than two spoonfuls of the first runnings of the simple water of laurel leaves killed, within a short time, a healthy young woman, previously producing violent convulsions. Various have been the speculations respecting the action of this poison. It has been supposed to affect exclusively the vital functions, as it produces death independent of sleep; but the brain is the great source of every power, and we are not yet prepared to say, that different portions of it may be affected, to any considerable degree, without an affection of the whole; or that functions of any kind are connected with a determined part of the organ. The disputes, whether it coagulates or dissolves the blood, are still more trifling; for the extravasations observed are very certainly owing to a loss of tone in the vessels. It has been employed as a medicine in the cure of intermittents; in resolving scirrhus

tumours, and in phthisis pulmonalis; but neither its dose nor its powers are so properly ascertained as to enable us to speak of it with precision; and its deleterious effects are so striking, as to deter us from even the most cautious trial.

Although the poison of laurel appears to consist in the essential oil which it affords in distillation, yet it is suspected that an infusion of the leaves is also injurious. Even the flavour communicated in some galenical and culinary processes has been dreaded, though without reason. The mucilage dissolved with the essential oil seems a sufficient guard.

It hath been generally observed, that if the animals that had swallowed this poison vomited it up readily, they recovered; but its action seems too speedy on the human race to hope for relief by any means. See VENENUM; Wilmer on Poisonous Vegetables; and Cullen's *Materia Medica*.

LAU'RUS ALEXANDRI'NA, (from *laus*, *praise*; as it was the reward of victors). *Hippoglossum epiglossum*, *daphne*, *diglossum*, *epiglottis*, *ruscus latifolius*, *bonefucia*, *coracobotane gazar*, *uvularia*; *ruscus hippoglossum* Lin. Sp. Pl. 1474, LAUREL OF ALEXANDRIA. The root of this plant is knotted at the head; the stalks tough and pliant; the leaves placed alternately; on the middle of the back of each grows a small mossy flower, succeeded by a red berry. It grows in the mountainous part of Italy and Hungary, and is said to be diuretic.

LAU'RUS VULGA'RIS, *diahexapela diahexapte*, COMMON LAUREL, OR BAY TREE, *laurus nobilis* Lin. Sp. Pl. 529; is an evergreen, with oblong, stiff, smooth leaves, flowers of a palish yellow colour, followed by oblong dry berries, containing, under a thin black skin, an horny shell, within which are lodged two dark brownish seeds joined together. It is a native of the south of Europe, and common in our gardens. The flowers appear in April or May, the berries ripen in September; but those which are used in the shops are generally the fruit of the *laurus Alexandrina*, from the Mediterranean.

The leaves have a light agreeable smell, and a weak aromatic rough taste. In distillation with water they yield a small quantity of a very fragrant essential oil; and with rectified spirit a moderately warm pungent extract. They are, however, rarely employed except in an enema, and the decoctum pro fomento, Pharm. London; though sometimes the infusion is drunk as tea. The berries are stronger than the leaves, and yield more essential oil: the expressed oil is fluid and insipid; but when the berries are ripe and boiled in water they afford a thick oil of a yellowish green colour, the oil of bay, which is bitter, acrid, and an useful application in palsies, or nervous disorders. The oil of bay berries is called *daphnelæon* and *oleum laurinum*. The berries are an ingredient in the emplastrum cumini; and Bergius thinks them stomachic, resolvent, promoters of the menses, urine, and perspiration, recommending them, however, only in hysteria. They have long been thought to act with peculiar power on the uterine system, and improper to be used during pregnancy. The essential oil of the berries may be taken in doses of from one to five or six drops on sugar, mixed with mucilage, or in the spirit of wine.

LAU'RUS CA'SSIA. See FOLIUM.

LAU'RUS RO'SEA. See NERION.

LAVA'CRA, (from *lavo*, to wash). WASHES, designed to improve the skin.

LAVE'NDULA, (from *lavando washing*; because it was used in baths). LAVENDER, *stachas*.

LAVE'NDULA LATIFO'LIA, *nardus Italica*, *spica mas*, *pseudonardus aspic*, COMMON BROAD LEAVED LAVENDER, OR SPIKE LAVENDER, *lavendula spica* Lin. Sp. Pl. 800. β , is a shrubby plant, with its leaves set in pairs, the stalks square while young, and round when old: on the tops of the branches are naked spikes of bluish, sometimes of white, flowers; and this species hath by much the larger spike, though the flowers are less. Of all the verticillated plants, this alone bears a spike, and from hence its trivial name is taken. It is common in the southern parts of Europe; stronger both in smell and taste than the narrow leaved; and by distillation yields near twice the quantity of essential oil, which is both heavier and more pungent than that from the other kind, but of a less pleasing flavour. The water and spirituous extracts from each sort are nearly alike.

In the south of France, where both species are indigenous, the broad leaved is only used for obtaining the oil called *oil of spike*, named *daveredon*, and *oil of aspic*, which, if genuine, is limpid, though sometimes yellowish. The flowers contain almost all the oil, and should be macerated some days before they are distilled. This oil is adulterated with oil of turpentine, and with rectified spirit of wine; but, if genuine, it dissolves sandarac, and copal; and is the best known solvent of amber.

LAVE'NDULA ANGUSTIFO'LIA, *spica femina*, and *vulgaria*, *pseudo nardus*, COMMON LAVENDER, SPIKE, OR NARROW LEAVED LAVENDER, *lavendula spica* Lin. Sp. Pl. 800. α . The leaves of this variety are very narrow and somewhat hoary; native in the southern parts of Europe, but growing in our gardens vigorously. The flowers appear in June or July, are very fragrant and agreeable, bitterish, and pungent; sometimes used as a mild stimulant and corroborant, in vertigos, palsies, tremors, and other debilities of the nervous system. Dr. Cullen asserts that, both externally or internally, it is a powerful stimulant of the nervous system, chiefly exciting the nerves of the animal functions, seldom those of the vital. It will consequently be safer in palsies than the warmer aromatics, if not given in a spirituous menstruum, or with more heating aromatics.

Water extracts by infusion near all the virtue both of the flowers and leaves; but the flowers are greatly superior: they afford the most oil when ready to fall off spontaneously and the seeds to appear.

The essential oil when fresh, and from flowers in perfection, is of a pale yellow colour, of a pungent taste, very fragrant, and of the peculiar smell admired in the flowers. These may be separated from the plant by drying, and then gently beating them; they should be immediately committed to the still, and the process conducted with a gentle heat. The oil is given internally as a cordial, from one drop to five, and used as a stimulant in palsies, lethargies, and the various debilities of the nervous system, particularly of the animal functions. Murray forbids it when any danger from stimulating the sanguiferous system exists. If soft paper moistened with it is applied to any part infested

with cutaneous insects, as the pediculi inguinales, they will soon be destroyed.

Rectified spirit extracts the oil most completely, and in distillation carries some of the odoriferous part with it. The *simple spirit*, according to the London college, is prepared by adding a gallon of proof spirit to a pound and half of the fresh flowers, and distilling five pints. The formula for the *compound spirit* follows: R. spt. lavendulæ m. libras tres, rosmarin. m. ℥ i. corticis cinnamomi contusi, nucis moschatæ contusæ singulorum, p. unciam dimidiam; santali rubri, p. ℥ i. Digere per dies decem et cola. Pb. Lond. 1788. This used to be called the *English palsydrop*, or *English drop*. The dose is from ten drops to a tea spoonful. See Lewis's *Materia Medica*.

LAVAPRA'TAS. See MAMANGA FRUTEX.

LA'VER, (from *lavo*, to wash, plants generally found in streams by which they are washed). A name for the *becabunga*, *sium*, *nasturtium aquaticum*; but more commonly applied in the west to the sea weed; *ulva umbilicalis* Lin. Sp. Pl. 1633. See ALIMENT.

LEVIPE'DIUM, (from *lavo*, to wash, and *pes*, the foot). See PEDILUVIUM.

LA'XA CHIMO'LEA. A PURGING MEDICINE, principally designed for the venereal disease. Paracelsus. Johnson says it is a salt which grows on stones, resembling in appearance the anatron, or usnea lapidea, *lichen cholybeiformis* Lin. Sp. Pl. 1623.

LAXA'TOR MEMBRA'NÆ TY'MPANI, (from *laxo*, to relax). This muscle arises from the upper part of the bone, above the membrana tympani, runs inward, and is inserted into the thick process of the malleus; *mallei musculus internus* Winslow.

LAXA'TOR EXTE'RNUS; *externus tympani auris*; rises in the upper sinus of the auditory passage, and is inserted in the membrana tympani, with a slender tendon to the malleus, drawing the membrane upward and outward.

LAZARETTO. See PESTIS.

LA'ZARI MO'RBUS, or MA'LUM. The DISEASE OF LAZARUS. See ELEPHANTIASIS.

LEAVEN, strictly speaking, is dough which has attained the acetous fermentation. It sometimes, however, means beer in a state of fermentation, when the air is entangled so as to form barm or yeast. See FERMENTUM.

LECHE'NEON. See CEREBRUM.

LECTUA'LIS MO'RBUS, (from *lectus*, a bed). A disease which confines the patient to his bed.

LE'CTULI, (from *lectus*). COUCHES, stuffed with proper ingredients coarsely powdered, whose qualities were supposed to affect the patient laid on them.

LE'CTULUS. See EPITHEMA.

LE'DON CRETE'NSE. See LADANUM.

LE'DUM PA'LUSTRE, Lin. Sp. Pl. 561; *cistus ledon*, *rosmarinum sylvestre*, MARSH CISTUS, or WILD ROSEMARY, rises with a slender shrubby stalk about two feet high, dividing into many slender branches, garnished with narrow leaves, not much unlike those of the heath. The flowers are produced in small clusters at the end of the branches, shaped like those of the strawberry tree, but spreading wider at the top, of a reddish colour, and succeeded by seed vessels, filled with small seeds which ripen in autumn. It grows

naturally upon bogs and mosses in many parts of Yorkshire, Cheshire, and Lancashire; hath a strong though fragrant smell, and is bitter to the taste. It is considered to be possessed of sedative powers, from its narcotic and inebriating qualities; and has been said, without any previous evacuation by emetics, and purgatives, alone to cure the dysentery. See Linnæi *Materia Medica*, and Richter's *Observations*.

LEGUMINO'SA. See FABAGO.

LEGU'MEN, (from *lego*, to gather, usually gathered by the hand). The seeds of the leguminous plants are called *fulcæ*, as pease, beans, &c. Ray calls all those plants *leguminous* which have a papilionaceous flower. See FARINACEA.

LEIO'PODES, (from *λειος*, plain, and *πους*, a foot). EVEN FOOTED; *planus*, SPLOY FOOT. Those the soles of whose feet are without the usual hollow part.

LEIPHÆ'MOI, (from *λειπω*, to be deficient, and *αιμα*, blood). Those who have too little blood.

LEIPODE'RMOS, (from *λειπω*, and *δερμα*, the skin). See PREPUTIUM.

LEIPOPSY'CHIA, (from *λειπω*, and *ψυχη*, the soul or life). A FAINTING FIT, LANGUOR; synonymous with adynamia.

LEIPOTHY'MIA, (from *λειπω*, and *θυμος*, the mind). A FAINTING FIT, A SWOONING. See LIPOTHY'MIA.

LEIPY'RIA, (from *λειπω*, to leave, and *πυρ*, heat). A dangerous species of tertian, in which the internal are scorched, whilst the external parts are cold.

LEMNIA TE'RRÆ. EARTH OF LEMNOS, the dried pulp of the adansonia baobab. See BAOBAB.

LE'MPNIAS CA'LCIS. SCALES OF BRASS, which separate when beat with a hammer.

LE'NOS, (from *λαινω*, to bruise). Hollow troughs where grapes are bruised. In surgery, a channel or excavation, made in some machines for extending and reducing fractured bones. Hippocrates. See CEREBRUM.

LENS, (è *lentore*, viscosity, from their glutinous quality). LENTILS, *phace*, or *phæcos*, are shaped like tares, but less, and are a flatulent indigestible food; *eryum lens* Lin. Sp. Pl. 1039. It is not now used in medicine. Lens is also the appellation of the crystalline humour of the eye, so denominated from its shape. See OCULUS.

LE'NTA FE'BRIS. SLOW FEVER. See HECTICA.

LENTI'CLARIA, (from *lenticula*, a lentil). See MILLEFOLIUM.

LENTI'CLÆ, LENTI'GENES, (dim. from *lens*). A SMALLER SPECIES OF LENTILS, and FRECKLES on the face or breast. See EPHELIDES, EFFILA, and also PECTICHIA.

LENTI'CLA PALU'STRIS. DUCK NEAT, *lens palustris*, *aquatica*, *lenticularia minor*, *lemnina minor* Lin. Sp. Pl. 1376; grows on the surface of stagnant water, and is in appearance simple and foliaceous; its roots slender, capillaceous, and pellucid. Externally it is supposed to be cooling.

LENTI'CLA PALU'STRIS MA'JOR, and AQUA'MICA TRISU'LCA; *hederula aquatica*, *lemnina trisulca* Lin. Sp. Pl. 1376; its qualities are similar to the former.

LENTICULA'RE. A LENTICULAR; A RUGINE.

LENTICULA'RE OS, (from *lenticula*, *lentil*). A name of the fourth bone in the first row of the wrist; *os orbiculare*, and *pisiforme*.

The os lenticulare, or orbiculare, of the ear, Dr. Hunter thinks, is part of the incus, as its extremities stand upon a narrow neck, and are soon broken off: in the adult it is one continued bone with the incus.

LENTICULA'RES, GLA'NDULÆ, (from the same,) small glands of the intestines, so called from their size. See PETECHIÆ.

LENTI'GINES, (from *lens*, a *lentil*). FRECKLES. See EPHELIDES.

LENTI'SCUS, (from *lentisco*, from the clamminess of its juice). *Mastiche*; the LENTISK OR MASTICH TREE, *Pistachia lentiscus* Lin. Sp. Pl. 1455, is an evergreen, with soft branches hanging downwards, and small stiff leaves pointed at both ends. Some trees produce reddish flowers, others blackish berries with white kernels: each is a native in the southern parts of Europe, but bear the usual winters of our climate. We chiefly receive it from Aleppo and Smyrna, but in Turkey, where it grows, plantations are made for the sake of the resinous gum, called *mastich*; though the Indian mastic is called *moll*. It is obtained from incisions made in the trunks, and flows in drops in August. The wood is sometimes brought from Marsilles, in thick knotty pieces, covered with a brownish bark; internally of a whitish or a pale yellowish colour.

The wood is mildly balsamic and astringent; the small tough sprigs are stronger than the larger ones, and the bark is more so than either. No part is of much value in medicine; though a decoction of the wood hath obtained the name of *aurum potable*. The wood itself has been highly extolled in dyspepsia, gout, hæmorrhages, and dysentery. The resin, usually called *gum mastich*, by means of gum arabic, is rendered miscible with water, and supposed to possess the virtues of turpentine, and is sometimes used as a masticatory. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

LENTI'SCUS FOLIS SPINOSIS, FLORE SPICATO, &c. See BONDUCH INDORUM.

LENTOR, (from *lentus*, *viscid*). A VISCIDITY OR SIZINESS; in the humoral pathology, the supposed source of many diseases. See MORBI FLUIDORUM.

LE'O, (from the Hebrew *levia*). The LION, the name of several preparations of the Spagirists, of the leprosy, &c.

LEONI'NA LE'PRA, or LEONTIA'SIS, or LE-O'NTION, (from *leo*, the *lion*, because lions are said to be subject to it). A variety of the ELEPHANTIASIS.

LEO'NIS OS and O'RA SÆ'VA; from its prickly mouth. See ANTIRRHINUM.

LEO'NTICE VE'TERUM. See CACALIA.

LEO'NTODON, (from *λεων*, the *lion*, and *odus*, a *tooth*). See DENS LEONIS.

LEONTOPO'DIUM, (from *λεων*, and *πους*, a *foot*, from its supposed resemblance,) *filago Alpina*, *leontopodium majus*, *gnaphalium Alpinum*, LION'S FOOT, *filago leontopodium* Lin. Sp. Pl. 1312, grows on hills, and flowers in July. The bruised roots were once famed for removing the blackness of bruises in the skin.

LEONU'RUS, (from *λεων*, a *lion*, and *ουρα*, a *tail*). See CARDIACA.

LEPIDI'UM, (from *λεπις*, a *scale*; from its use in

cleansing the skin from scales). *Piperitis*, *raphanus sylvestris*, *iberis*, *Dionysius*, POOR MAN'S PEPPER, PEPPER WORT, DITTANDER, *lepidium latifolium* Lin. Sp. Pl. 899, is a plant with undivided leaves, small white flowers on the tops of the stalks, followed by heart shaped pods; perennial, growing wild on the sides of rivers and shady places: it flowers in June and July. The whole plant is pungent like pepper.

LEPIDI'UM A'RABIS. See DRABA.

LEPIDI'UM GRAMINEO FOLIO, *Iberis cardamantica*, *agriocardium*. SCIATICA CRESSES; *lepidium iberis* Lin. Sp. Pl. 900. This species hath long narrow leaves; the lower of which are on long pedicles and serrated; the upper entire, without pedicles; annual, and raised in our gardens for culinary use.

All these plants, when fresh gathered, have a quick, penetrating, pungent taste, though almost dissipated in drying; it is retained in the expressed juice; extracted by water and by spirit; and rises with both in distillation. In external applications they have been used against the sciatica; internally in intermittents, chronic rheumatism, and palsy.

LEPIDI'UM MONSPELIACUM. See PLUMBAGO.

LEPIDOCARPODE'NDRON, (from *λεπις*, a *scale*, *καρπος*, *fruit*, and *δενδρον*, a *tree*, because its calyx is scaly). All the species are natives of the Cape of Good Hope, near Table Mountain, and arranged by Linnæus under the genus *leucandron*; but neither seems entitled to attention in a medicinal view; so that we need not distinguish them more minutely.

LEPIDOI'DES SUTU'RA, (from *λεπις*, a *scale*, and *ειδος*, *likeness*). See SUTURÆ.

LEPIDOSARCO'MA, (*λεπις*, a *scale*, and *σαρξ*, *flesh*). A sarcomatous and scaly tumour of the mouth. Severinus.

LEPORI'NA LA'BRA. See LABIA LEPORINA.

LEPORINUM RO'STRUM, (from *lepus*, and *rostrum*, a *beak*). The piece of flesh often seen between the divisions of the hare lip.

LE'PRA, (from *λεπις*, a *scale*). The LEPROSY. See ALPHUS.

The leprosy is a chronical disease; in warm climates infectious, but not evidently so in cold countries; though its infectious nature was formerly suspected, and the unhappy victims separated in distinct establishments from the rest of mankind. Dr. Cullen places this disease in the class *cachexiæ*, and order *impetiginis*; defining it the skin rough, with white, furfuraceous, chapped eschars, sometimes moist underneath, and pruriginous. Of the only species known, Sauvages notes six varieties; but the *lepra Græcorum* and the *lepra ichthyosis* only occur in this country.

The leprosy of the Greeks has been very often confounded with the *lepra Arabum*, which, however, is a very different disease, and already noticed in the article ELEPHANTIASIS, q. v. The latter appears to be rather a disease of the constitution, and affects the hair, not only of the head, but over the whole body; attended with deep ulcerations, loss of sensation in the swollen parts, and fœtid sweats. The *lepra*, on the contrary, seems to be an affection of the cutis vera only, whose papulæ are either enlarged, or tumours of a different nature are formed on it, which press outwards on the cuticle, and occasion scaly indurations on the surface.

The first appearance of leprosy is discovered by reddish shining elevations on the skin, often on those parts where the bone is covered only by the integuments, as the skin, on the outside of the fore arm. A thin white scale is soon formed on the top of these elevations, which quickly flatten, while their bases enlarge. The enlargement of their bases continues; but the separate patches constantly preserve a roundish form, though, when they approach and unite, it is generally elliptical. When the scales either fall off by the rubbing of the linen, or are separated by violence, they are soon reproduced; but the surface below appears red and wrinkled, though the rugæ do not resemble those of the cuticle, nor are they continuations of the furrows in the contiguous sound surface. *Lepra* does not appear to be peculiarly the disease of the hairy scalp, though we have generally found traces of it in this part of the body, when it has before appeared on the surface. At the edge of the hair on the forehead it often first attacks, though more frequently the leg, just below the knee; or the fore arm, rising gradually to the trunk.

The stiffness of the skin is troublesome, and the itching, which is extremely distressing in hot climates, is, even in these, troublesome while the patient is warm in bed; but the general health seems in no respect affected, and nature, without assistance, will not relieve. The signs of amendment are the diminution of the ridge round the patch, the scales not reproduced when rubbed off, and the appearance of a red more natural cuticle in the centre. All the patches at the same time begin to assume a more healthy look.

The *lepra* is said to be hereditary. We own that we have not found it so; but Dr. Willan thinks a predisposition to it may be transmitted from parents. In more than one family where there was this tendency, those in whom it appeared on the surface, and who were relieved by medicine, lived long afterwards in a healthy state, while those in whom it did not appear, died young, apparently consumptive. In a constitution of this kind we once observed the phthisis from calculus. The diseases, however, in these cases, were not, perhaps, strictly leprous, though nearly resembling it. In one instance mania supervened on the disappearance of a true leprosy.

Dr. Willan thinks that a slow pulse, or a languid circulation, with what may be expected to attend them, a deficiency of perspiration, constitutes a fundamental part of the predisposition. We cannot say that we have seen the disease most frequently in such constitutions, nor does our recollection furnish any particular habits in which it has appeared most frequent. An indulgence in spirituous liquors has appeared a remote cause; but we have not seen any peculiar diet contribute to it. Those who work among dry powders are said to be subject to it; but we have only seen what resembles it in those who follow one occupation of this kind, viz. millers. Wheat, when ground, rapidly absorbs moisture, and every part of a miller's house is dry. The hands of the labourers are consequently often chopped, sometimes covered with eruptions; but the disease seemingly differs from true *lepra*. Bricklayers' labourers suffer from lime, and laboratory men from acids; in neither, however, is this disease peculiarly prevalent.

Lepra is a complaint of singular obstinacy, and often resists the best concerted plans. As it appears not to

be influenced by diet or situation, and not to be hereditary, it may seem to be merely local; and the ancient physicians, after bleeding and purging, applied the most acrid substances from the animal, vegetable, and mineral kingdom, to cure it. These undoubtedly remove the scales, but they are soon reproduced; for the cause is beyond the reach of applications to the surface only. When internal medicines have in part removed the cause, liniments of tar, sometimes with sulphur, at others with kali, or alum, are often useful. The warm bath is a pleasant and salutary application, whose effects extend beyond the surface; but which also relax the hardened scales, and immediately remove part of the inconvenience, the stiffness. The sulphur waters of Harrowgate and Moffat combine both views, and are highly useful. The Harrowgate water may be easily imitated for this purpose by uniting the *hepar sulphuris* with sea salt.

The bath waters combine the good effects of a warm bath with an internal medicine which excites the action of the extreme vessels, an object of considerable importance in the cure of *lepra*. The minutes of the Bath hospital, on this subject, published by Dr. Falconer, give a very favourable prospect of its advantages. Sea water, used as a bath, both warm and cold, has been equally useful, especially if, like the Bath waters, it is taken internally. Other external preparations have been chiefly mercurial, as a solution of the *hydrargyrus muriatus*, and the unguentum, *hydrargyri nitrati* of the London Dispensatory. Dr. Willan does not think these applications preferable to the tar ointment.

Though it is admitted that the *lepra* is most commonly a topical disease, yet, from the thickness of the scales, and from the chief seat being in the *cutis vera*, topical remedies alone scarcely affect it. Medicines, therefore, which excite the action of the cutaneous vessels are chiefly of service. The principal of these is mercury and antimony. The most powerful mercurial is undoubtedly the *hydrargyrus muriatus*, which often succeeds. It is the active ingredient of Spilsbury's drops, which are highly celebrated; and the same remedy would be more celebrated in regular practice, could the scientific physician condescend to adopt the pompous boasts of the empiric, or was the same confidence placed in the man of experience and judgment, as in the pretending illiterate quack. Other mercurials are also useful, but perhaps not in an equal degree. Antimonials alone will not cure the complaint; but with calomel, as in the pill of Dr. Plummer, they will often succeed, if the calomel be not triturated too long with the sulphur auratum. We have usually directed it to be added to the mass, after the other ingredients were united. The advantages of these medicines are assisted by the warm diaphoretics of the vegetable kingdom, as the *mezereon*, the elm bark, the *sarsaparilla*, the *guaiacum*, and *sassafras*. We place them in the order of their activity, for the *mezereon* is most effectual; but combining them, as in the Lisbon diet drink, renders them more useful.

The mineral acids have lately succeeded in removing slighter kinds of this disease, and we think we have found them more effectual than the *aqua kali puri* recommended by Dr. Willan. The tincture of *cantharides* is better adapted to relieve tettery eruptions than *lepra*; in the latter we believe it very generally fails. Every plan of cure we have found greatly assisted by a

milk and vegetable diet, interposing, every two or three days, a purgative of neutral salts. This method also most effectually prevents a relapse.

We need scarcely mention many other remedies recommended for this purpose, as the water dock, if this be really the herba Britannica; the dulcamara, which seems to have succeeded with Dr. Crichton; the cucumbers, recommended by Willis; the roots of hellebore, particularly the black hellebore, used by the ancients, and particularly noticed by Oribasius. The flesh of vipers, or of chicken nourished by it, will scarcely at this time be trusted, though highly commended by the same author.

See Aretæus, iv. 13; Lorry de Morbis Cutaneis; Mercurialis de Morbis Cutis; Falconer in the Memoirs of the Medical Society of London; London Medical Transactions, vol. i. and ii.; Medical Observations and Inquiries, vol. i. p. 201; London Medical Journal, vol. i. p. 94; Willan on the Diseases of the Skin, order ii. vol. i. p. 112, &c.

LE'PRA A'RABUM; usually considered as synonymous with the ELEPHANTIASIS, q. v. See also LEPRA.

LE'PRA GRÆCORUM, *alba, nigra, and impetigo* of Celsus. See LEPRA.

LE'PRA ICHTHYOSIS. FISHY LEPROSY; *albaras nigra* of Avicenna. This term is often applied by Avicenna to elephantiasis, and we think, with Dr. Willan, that the *albaras nigra* of the Arabians, and the black morphea of the Greeks, are varieties only of elephantiasis. See ALPHOS.

The lepra ichthyosis is a more general affection of the whole skin, while the lepra græcorum appears in patches. The name is derived from the imbricated situation of the scales, which resemble those of a fish; but round the elbow and knee they are round, prominent, and small. The neck of the scales is small, but they are flatter as they rise, and often very hard and sharp, rendering the parts hard and brittle. On the inside of the arms and thighs, in the bending of the knees and elbows, and wherever the skin is thin, there are no scales. The scales are sometimes intersected with white furrows, and the surface is often broken by inflamed and painful boils.

If the scales are picked off in warm water they do not again return, but the skin beneath is dry and hard. It must, however, be often moistened, and rubbed as much as it will bear without pain. A disease of this kind is described in the fourteenth volume of the Philosophical Transactions (Shaw's Abridgement, iii. 43.) in a letter from the famous Lewenhoeck, and another in the thirty-seventh volume (Abr. vii. 543). The sequel of this last case is given in the forty-ninth volume, and the disease there appears to be hereditary. A complaint so closely interwoven with the texture of the skin would be probably intractable; and the only method of relief is that mentioned, viz. drawing out the scales after maceration in warm water. Mercury has been tried without success. A less degree of this complaint occurs in worn out constitutions, in anasarca, &c. where it appears to be only an enlargement and thickening of the natural scales of which the cuticle consists.

LE'PRA NIGRICANS differs from the LEPRA GRÆCORUM, q. v. in colour, and in appearing as a disease more strictly connected with the constitution. The spots are smaller in size, the border livid, and the in-

crustations, which are thin, seem to derive their hue from the lividness of the skin below. When the scales are removed they are not so soon restored, and the discharge is bloody. It affects persons exposed to great fatigue, in damp situations, and has been considered as the true lepra in constitutions where the blood is greatly dissolved. The remedies of lepra are useless or injurious; and bark, mineral acids, with sea bathing, contribute to the cure. The *black scurvy of the West Indies* seems to be the same disease, though like this, allied to elephantiasis, since a numbness is felt in the fingers and toes, the voice is hoarse, and fever supervenes.

LEPTOPHO'NIA, (from λεπτος, slender, and φωνη, the voice). See PARAPHONIA.

LEPTOPTYRON, (from λεπτος, thin, and πτυρον, bran). See FURFUR.

LE'ROS, (from λερω, to trifle). See DELIRIUM.

LESE'OLI MO'RBUS. See ICTERUS.

LESE'OLUS. A diaphanous salt, which cures the jaundice. Paracelsus.

LETHA'RGUS, (from ληθη, forgetfulness, and αργος, slothful). LETHARGY; *veternus*. See CAROS and APOPLEXIA.

LEUCANTHEMUM, (from λευκος, and ανθεμος, as it only differs from the chrysanthemum in the white floret). A name also for the common and other species of camomile. See CHAMÆMELUM.

LEUCA'NTHEMUM BE'LLIDIS FA'CIÆ. See BELLIS MAJOR.

LEUCA'NTHEMUM CANARIE'NSE; *chamæmelum Canariense*. The effects are the same as those of the pelitory root, if chewed.

LEUCA'NTHE VE'TERUM, (from λευκος, white, and ακανθα, a thorn). See CALCITRAPA OFFICINALIS.

LEU'CAS MONTA'NA. See LAMIUM LUTEUM.

LEU'CE, (from λευκος, white). See ALPHUS.

LEUCOI'UM, (from λευκος, white, and ιου, a violet). See CHEIRI, and BULBONACH.

LEUCOLA'CHANON, (from λευκος, white, and λεχανον, a herb). See VALERIANA SYLVESTRIS.

LEUCO'MA, (from λευκος, white). See ALBUGO.

LEUCO'MA NEPHE'LIIUM. See ACHLYS.

LEUCONYMPHÆ'A, (from λευκος, white, and νυμφαια, water lily). See NYMPHÆA.

LEUCOPHLEGMA'TIA, (from λευκος, white, and φλεγμα, phlegm). In leucophlegmatia, Aretæus observes, the flesh is not wasted as in anasarca, and it is more easily cured: indeed it is only the beginning of anasarca. Sometimes this word signifies an *emphysema*.

LEUCOPI'PER, (from λευκος, white, and πιπερις, pepper). See PIPER ALBUM.

LEUCORRHŒ'A, and LEUCORRHOIS, (from λευκος, white, and ρεω, to flow). See FLUOR ALBUS.

Since that article was printed, we find cantharides proposed as a remedy for this disease, in consequence of its resemblance to gleet. It was given, it is said, by Greenfield with success; and, indeed, a topical stimulant may be occasionally useful. The balsam. copaiba is probably no more.

LEVA'TOR, (from *levo, to lift up*). The name is given to many muscles, whose office it is to elevate different parts into which they are inserted, viz.

LEVA'TOR PALA'TI MO'LLIS, rises from the basis of the skull, near the articulation of the lower jaw, runs

down the fauces, passes inwards and forwards, spreads itself on the palatum molle, and goes to the uvula.

LEVA'TOR PA'LPEBRÆ SUPERIO'RIS, ELEVA'TOR, *aperiens palpebrarum rectus*, named from its straight progress and use by Fallopius and Douglas. It arises on each side from the bottom of the orbit by a small tendon, and as the fleshy fibres of the muscle pass over the globe of the eye, they gradually spread, and afterwards terminate by a broad tendinous expansion on the superior part of the tarsus belonging to the upper lid.

LEVA'TOR SCA'PULÆ, *levator proprius* of Winslow; *musculus angularis, seu patientiæ musculus* is divided at its origin into four little muscles, from the transverse processes of the four superior cervical vertebræ. The branches join, and form one muscle on each side, inserted into the bases of the respective scapulæ above the spine.

LEVATORES ANI, and ELEVA'TORES, rise with a broad base from the symphysis of the os pubis, the internal part of the ileum, the membrane of the obturator internus and coccygæus, and the sharp process of the ischium, directing their course downwards as to a centre, and blending part of their fibres with those of the sphincter, the acceleratores urinæ, and the anterior part of the extremity of the coccyx, surrounding the prostate gland, the vesiculæ seminales, and the neck of the bladder, which they contribute to support. They contribute to expel the fæces; but do not, as is generally supposed, very powerfully compress the vesiculæ seminales in coition.

LEVATORES COMMUNES LABIO'RUM, *elevatoros labiorum*, rise from the cavity under the os jugale, in the os maxillare, and are inserted, with the zygomaticus major and others, into the angle of the lips, on each side.

LEVATORES COSTARUM, *supracostales*, rise from the transverse processes of the vertebræ, and are inserted into the ribs: they are divided into the longiores and the breviores. The latter rise from the transverse processes, and are inserted into the next rib; the longiores run over one rib, and are inserted into the next.

LEVATORES LABII INFERIO'RIS, ELEVATORES, *facimentale, incisivus inferior* of Winslow, and *levator menti* of Albinus, rise from the sockets of the incisores and are inserted into the lower lip.

LEVATORES LABII SUPERIO'RIS, ELEVA'TORES, rise from the os maxillare, and descend obliquely under the skin of the upper lip, orbicularis muscle, and the outer part of the alæ nasi.

LEVIGATIO, (from *levis, light*). The pharmaceutical operation, by which hard substances are reduced to an impalpable powder; but unless the instrument is very hard, as much of the stone as of the medicine may be discovered in it. In many instances the substances are levigated with water, and suffered to dry on chalk; sometimes the fine powder is separated, after levigation, by washing. If the whole is agitated in water, the coarser parts will subside, while the finer ones may be poured off with the fluid, and will subside after a longer rest. Thus the powder may be obtained of any degree of fineness, according to the time suffered to elapse before the water is first poured off. We observe, however, in the Encyclopædia Britannica, a very convenient instrument called a *fanner*, which separates the finer powder by a blast of air, on the same principle as the machine for winnowing corn acts, but know not

how it really succeeds in practice, so that we shall not fill our page with the description.

LEVI'STICUM, (from *levo, to assuage*; from its relieving painful flatulencies). *Ligusticum, angelica montana perennis*. COMMON LOVAGE; *ligusticum levisticum* Lin. Sp. Pl. 359; is a tall umbelliferous plant, with leaves divided like those of smallage; the root thick, fleshy, juicy, branched, and of a brown colour outwardly; a native of the south of Europe. It is perennial, flowers in June, and its seeds are ripe in August. This plant hath a strong and peculiarly ungrateful smell: to the taste it is warm and aromatic, resembling angelica, but less agreeable; and its yellowish gummy resinous juice much resembles opoponax.

The seeds are warm and pungent, of a more agreeable flavour; the roots sweetish, and more pleasant than the leaves; its essential oil is in a small proportion, and an extract made with rectified spirit retains both the aroma and the sweetness. Lovage is similar to angelica and masterwort, as a carminative, sudorific, and deobstruent, and might be a good substitute for either, had we not more effectual medicines in the galbanum and asafœtida. The leaves, eaten as salad, are accounted emmenagogue. See Raii Historia; Lewis's Materia Medica.

LE'VITAS INTESTINO'RUM, (from the food passing quickly). See LIENTERIA.

LIBANO'TIS, (from *λίβανος, frankincense*). *Cachrys, cachrysea*, FENNEL HERB, FRANKINCENSE, *athamanta libanotis* Lin. Sp. Pl. 351, more probably *laserpitium ferulaceum* Lin. 358, grows on mountains in Italy and Sicily, and flowers in May. It is also a name for several sorts of *laserpitium, ferula glauco folio, ferula minor, rosmarinus, oreoselinum officii*, and several other plants.

LI'BERANS A'QUA. See CALCIS' AQUA' MAJUS COMPOSITA.

LIBIDO. See PRURITIS.

LI'BRA, (from *λίβρα, a pound*). See PONDUS.

LICHA'NDOS, (from *λειχῶ, to lick*; because used in the action of licking). FORE FINGER. See INDEX.

LI'CHEN, (from *λειχῶ, lambo, quia lambendo serpiant*;) a cutaneous disease called lichen, from its resemblance to the spots scattered over the tuberculated lichen. It is a papulous eruption, sometimes rising into tumours of a more considerable size; but in its milder forms rather a deformity than a disease. The term has been variously applied, and the eruption confounded with herpes, scabies, impetigo, &c. The confusion is of little consequence, since the complaint is usually trifling; and we may define it, with Dr. Willan, an extensive eruption of papulæ affecting adults, connected with internal disorder, usually terminating with scurf, recurrent, not contagious. This genus he divides into five species, the *lichen simplex, agrius, pilularis, lividus, and tropicus*. The first commences with slight feverish symptoms, which in a few days are relieved by distinct red papulæ about the cheeks and chin, or on the arms; and in three or four days the same appearances take place on the neck, body, and lower extremities, accompanied with an unpleasant sensation of tingling, aggravated during the night. The eruption fades in about a week, and the whole surface is covered with large scurfy exfoliations, which continue longest in the flexure of the joints. The period of its termination

is seldom the same in any two cases; and on different parts of the surface of the body there is some difference in the form of the papulæ. On the face they are large, rounded, often forming small tubercles like vari; on the neck, breast, and extremities, they are most distinct and acuminate; and on the hands they resemble obscure watery pustules, which exfoliate without any discharge of fluid. This disease most commonly affects persons of a weak irritable habit, and occurs about the beginning of summer or autumn, sometimes general, at others partial, occasionally disappearing or returning without leaving any scurf, and often without any previous fever. A light cooling diet, or if necessary, some easy laxative, is only necessary. Sometimes the simple lichen is chronic, and then styled *scurvy*; sometimes critical, and called *scabies critica*. It sometimes terminates in a dry tetter.

The *l. agrius*, from *ægyptus*, *immanis*, is preceded by a fever approaching the typhus. The eruptions are of a deep dark red, with an inflamed basis, itching and tingling after any stimulating food and drink, or in the warmth of the bed. In the morning the uneasiness is inconsiderable. Straw coloured pustules are occasionally intermixed, and by the continuance of the complaint the skin is thickened, chapped, and painful. The pustules are usually confined to the upper part of the body.

Its continuance is uncertain, and it sometimes appears and disappears; but if repelled, general constitutional disorder follows. If any wound is made by scratching, it is with difficulty healed, and the disease sometimes terminates in an ulcerated psora. This species differs from the former in the nature of the fever, the greater violence and obstinacy of the complaint. It is exasperated by mercurials, though calomel has been recommended in the beginning as a laxative; and the best medicines are the bark, with the mineral acids. We know not that a perpetual blister or an issue has been tried; but it appears a probable means of relief. The itching is best relieved by the spittle or a little rose pomatum.

The *lichen pilaris* is the lichen simplex, affecting chiefly, or exclusively, the roots of the hair, and from around the hair exfoliations take place. It differs in no respect from the first species.

The *lichen lividus* seems little different from petechiæ, with which they are often mixed, and the disease chiefly confined to the poor, whose diet is frequently unalimentary; it is best relieved by the bark and mineral acids. No fever precedes. Papular eruptions, resembling the lichen lividus, sometimes occur among the secondary appearances of lues; but in this last the papulæ are smaller, more numerous, more generally diffused; their points are, after some time, depressed; they do not disappear and return, but occasionally terminate in a foul ulcer.

The *lichen tropicus* is the prickly heat of tropical climates, resembling the papulæ produced by sweating in the more temperate. It appears without any preceding disorders of the constitution; but the papulæ, about the size of a small pin's head, are numerous, of a vivid red, and elevated so as to produce a considerable roughness in the skin; but no redness or inflammation surrounds them. The eruption is chiefly confined to those parts of the body which are usually covered, and sometimes appears on the forehead contiguous to the hair, though never on the palms of the

hands, the soles of the feet, or on the hairy scalp: flannel, or warm clothing, increases the number of the papulæ. Small pearly pustules, containing a limpid fluid, are often intermixed with the prickly heat, when perspiration is very copious, more especially on the breasts and about the wrists. They have no disposition to ulcerate, though violently scratched, but terminate in scales. A troublesome itching attends the prickly heat, and prevents sleeping during the night, with an acute sensation of pricking, which often also takes place suddenly after drinking any warm liquor. The eruption is sometimes stationary, appearing equally vivid in the day and night; sometimes quickly disappearing and returning, without any obvious cause; but whenever it continues for any length of time, the papulæ throw off minute scales, and are succeeded by a fresh crop, without leaving any vestiges on the skin. Persons of a fair complexion, with red hair, and a soft skin, are more liable to this eruption, and have it in the greatest quantity. Those of dark complexions have it slightly, or remain free from it. As the prickly heat is considered to be a salutary eruption, no attempts should be made for its repulsion. Its sudden disappearance is rather the effect of internal disorder than a cause, and occasioned by fever, or any slight complaint of the stomach: in the latter case a stimulus applied to that organ, as spirits, or warm liquors, reproduces it. Its appearance on the skin of persons in a state of convalescence is always a favourable sign. To alleviate the itching and tingling of the prickly heat, a light and cool dress, and avoiding warm liquors, have been found most servicable.

A vivid eruption of papulæ, somewhat analogous to the prickly heat, appears in our own climate, on the arms, hands, face, and neck of labourers, and other persons who use violent exercise during the hot months of summer. It produces a sensation of tingling, a smarting rather than of itching, and disappears in a short time without any particular consequences. See Willan on Cutaneous Diseases.

In veterinary medicine the term lichen is applied to a species of leprosy and warts which grow on horses' legs.

In botany it is called *liverwort*, and is a floriferous and seminiferous moss, whose flowery little heads are furnished with many grains, variously shaped, producing as they ripen several little monopetalous flowers. The seeds, which are small, flat, and orbicular, are contained in some peculiar open capsules, resting upon the plane of the leaves, and are sometimes found in the same plant that bears the little heads, sometimes in other plants of the same species. Besides these flowery heads, in some species there are unbellated heads of different figures, which produce neither flower nor seed. The pedicles of both species are for the most part naked, and proceed from no vagina. The leaves are of an herbaceous consistence, and of an indeterminate figure, widely spreading, and running out into various roots from their back part. Every plant under the name of lichen is warm and astringent; and this term is applied to the *muscus pyxidatus*, *hepatica vulgaris*, &c. besides the succeeding.

LICHEN ARBOREUS PULLUS, *muscus crustæ*. TREE LIVERWORT, *lichen plicatus* Lin. Sp. Pl. 1622, grows on trees, and is used instead of the pulmonaria arborea. It is astringent, and chiefly used in pulmonary hæmorrhages.

LI'CHEN CINE'REUS. ASH COLOURED GROUND LIVERWORT; *lichen caninus* Lin. Sp. Pl. 1616. It consists of roundish thick leaves, divided about the edges into obtuse segments, flat above, of a reticular texture below, fastened to the earth by small fibres, of an ash grey colour, by age turning darker or reddish. It grows on commons and open heaths, spreads quickly on the ground, and is found at all times of the year, but supposed to be most active from the end of autumn to the winter. A powder, called *pulvis antilyssus*, used to be formed of two parts of this moss, and one of black pepper: ʒi. ss. in half a pint of cow's milk, for four mornings successively, was to be taken fasting. (See HYDROPHOBIA.) It has now fallen into disrepute; and does not appear to be possessed of any useful degree of medicinal virtue.

LI'CHEN ISLA'NDICUS, Lin. Sp. Pl. 1611; *lichen terrestris*; *lichenoides*; and *rigidum*; ERYNGO LEAVED, EATABLE, ICELAND LICHEN, is a native of Britain, and grows both in Scotland and Wales. It is foliaceous, erect, large; leaves crowded, connected, about two inches high, stiff when dry, but soft and pliant when moist: they are variously divided, without order, into broad distinct segments, turned in at the edges, and fringed with short strong bristles; the upper surface is smooth, concave, shining, of a pale green, or chestnut colour, but red at the base; the under is smooth and whitish, a little pitted and sprinkled with very minute black warts: the fructifications are large, of a reddish colour, and placed on the lobes of the leaves. This plant is extremely mucilaginous, has a bitter and somewhat astringent taste, and is considered as a laxative and an anthelmintic in its recent state: but its bitterness and aperient quality are in a great measure destroyed by drying, or a slight infusion. The Icelanders make a flour of it, called *falgras*, either by first washing and cutting the plant into small pieces, or by drying it, putting it into a bag, which is well beaten, and working it into flour by stamping. This is tolerably agreeable and grateful food. As a medicine, Scopoli and Haller recommend it in coughs and consumptions; and it has proved efficacious in dysentery and diarrhœa. Dr. Hertz found it so successful in dysentery, that after the repeated administration of emetics and cathartics he seldom used any other medicine, to which he occasionally added opium. Dr. Crichton recommends it in *phthisis* attended with hæmoptoe and pituitous or mucous discharges; and thinks he has found it of considerable service. It is given in decoction, made by boiling one ounce and an half in a quart of milk, over a slow fire, exactly a quarter of an hour. The dose is about a pint in the day. If the milk disagrees, water may be used. This medicine has lately become fashionable; but we have only found it a mild nutrient. The bitter is apparently of the narcotic kind, and at times is cold and heavy on the stomach. If this is taken away by a slight previous infusion, a mucilaginous, or rather a farinaceous matter, only remains, without apparently any distinguishing property. At Berlin it seems to have been used with different success. M. J. C. Fritze thinks it a valuable medicine, even when purulent matter is expectorated; and he added to the decoction, either in milk or water, the flowers of St. John's wort and coltsfoot. F. Fritze, in his Clinical Annals, chiefly confines its utility to its

mildly nutritious powers; and Scheffer was usually unsuccessful with it, except in recent, apparently catarrhal, cases.

LI'CHEN PYXIDATUS, Lin. Sp. Pl. 1619, (from *pixis*, a cup, in consequence of its bearing little cups). See MUSCUS PYXIDATUS.

LICHENOI'DES, (from *lichen*, and *ειδος*, likeness). See LICHEN ISLANDICUS.

LI'EN, (from *λειος*, soft, or smooth). See SPLEN.

LI'EN SINA'RUM. See FABA ÆGYPTIA.

LIENTE'RIA, (from *λειος*, smooth, and *εντερον*, the gut). A LIENTERY. LEVITAS INTESTINORUM, q. v. In Dr. Cullen's system it is the fifth species of diarrhœa; defined a diarrhœa in which the aliments are quickly hurried through the body in a nearly undigested state. Fernelius attributes this disorder to a weakness of digestion, Friend to an obstruction of the intestinal glands, and Fr. Sylvius to an obstruction of the orifice of the lacteals. Actuarius observes, that an inveterate diarrhœa or dysentery most commonly produces the distemper. The fault is generally in the stomach, as the digestion is not complete; and the unaltered food producing an unusual impression, excites the action of the intestinal fibres, and probably also of the mucous follicles. The chief remedies are warm strengthening medicines, with moderate exercise and warm clothing. See DIARRHŒA.

LIENTE'RIA SPONTA'NEA. See DIARRHŒA.

LIGAME'NTUM, (from *ligo*, to tie). *Colligamen*, *copala*, *syndesmos*, a LIGAMENT. The ligaments are tendinous, inelastic, glistening bodies. Every articulated bone is furnished with a capsular ligament, which is composed of two layers: the external layer is the stronger, formed by the periosteum; the inner is thin and uniform.

This part of anatomy, though so important in many respects, has been, however, greatly neglected, if we look at those aids which are not derived from actual dissection. The representations of the ligaments have, in general, been mean, incorrect, and inelegant. While each bone is delineated so as to display every little prominence and furrow by Albinus and Le Sue; while each unimportant muscle is represented in all its varieties by Bidloo; the ligaments have been little noticed. The minute accuracy of Soëmmering cannot find, in the fasciculi of Haller, the discriminating genius of Albinus. De Corp. Fabrica, v. xxxi.

In Vesalius we perceive the ligaments of the lower limbs delineated, and in Winslow they are described. Walter has figured and described the ligaments of the lower extremities (Disput. Anatom. Halleri, vol. iv.); Schwencke, in his Hæmatologia, those of the acetabulum: but the first professed work in which all the ligaments were described and delineated, was that of Weitbrecht, published at Petersburg, 1742, in quarto. His dissections were numerous; and he not only collected the observations of former anatomists, but compared them with what his scalpel had shown. His engravings, however, imperfectly represent the objects; and some ligaments are omitted, particularly of the os sacrum. Yet till lately Weitbrecht was our only assistant, and his plates have been professedly copied in an elegant work on the bones by Losche, concluded at Erlang, 1796; and in another by Schenke, published at Leipsic in 1795. In these, however, the objects are

diminished, and the representations are consequently still more distant from nature.

Somewhat before these copies of Weitbrecht, Loder published his anatomical tables at Weimar, viz. in 1794; and, perceiving that this part of anatomy had received less attention than some others, introduced new plates of the fresh joints, from his own preparations. The abilities of the engraver were not equal, however, to the diligence and ability of the anatomist; yet Loder greatly excelled his predecessor. The order of time, rather than the improvement, leads us to speak of Mr. J. Bell's plates of the joints, subjoined to those of the bones. The errors of the osteology are, however, continued in the ligaments; and the plates are so miserably executed, that without the explanation no anatomist could guess at the object before him. Anatomical plates are, however, often miserably executed; and, in a Dictionary now publishing, we showed a view of the basis of the brain to several anatomists, who supposed it a herniary sac; and, indeed, every thing but what it was.

Morgagni long since observed, that many of the ligaments remain to be more accurately examined than in Weitbrecht's work; and that to which we have been indebted for our plates is, undoubtedly, the most perfect which has yet been published. We mean the Syndesmology of Caldani, published at Venice, in imperial folio, 1803. The elegance, the accuracy, and the minute precision of the descriptions have led us to copy from it freely; and we have engaged in this short account of what was before done, to show the importance of what we have added to the stock of the English anatomist.

LIGAME'NTUM ANNULA'RE. The appellation of ANNULAR LIGAMENT, or *frænum*, is given to that on each ankle and each wrist, rather on account of their use than their figure; they confine the tendons of the muscles which pass through them.

LIGAME'NTUM ARTERIO'SUM. See DUCTUS ARTERIOSUS.

LIGAME'NTUM CILIA'RE. White, striated, ligamentous fibres arise out of the choroid membrane, from the ciliary circle, which are covered with a black pigment, and are attached to the membrane of the vitreous humour, where it joins the crystalline lens. The fluctuating extremities of these striæ are spread on the edge of the lens, but not united with it. The whole is generally described under this term.

LIGAME'NTUM CO'LI DE'XTRUM. The mesentery having reached the end of the ileum joining the colon, the lamina which is turned to the right side forms a small transverse fold, distinguished by this appellation.

LIGAME'NTUM CO'LI SINI'STRUM. The mesentery, here called *mesocolon*, having passed below the left kidney, contracts and forms a transverse fold thus named.

LIGAME'NTUM CO'LLI VEL NUCHE. See CUCULLARIS.

LIGAME'NTUM CUTA'NEUM O'SSIS CO'CCYGIS. It passes anteriorly from the extremity of the os coccygis; is very slender, and divides into two portions at the orifice of the anus, which run in the *membrana adiposa*, and, when expanded, are inserted in the skin on each side of the anus: they continue to divaricate, and are lost on the two sides of the perinæum.

LIGAME'NTUM DENTICULA'TUM. Between the anterior and posterior bundles of fibres which form the spinal nerves, a ligament is connected by a number of threads, to each side of the pia matral covering of the spinal marrow, through its whole length, for its support. As this ligament is fixed by a number of teeth to the inner side of the sheath formed by the dura mater, it has been called *denticulatum*. The greater number of these teeth run transversely; some ascend, others descend; all split into fibres, which are incorporated with the fibres of the inner layer of the dura mater. From the conical lower end of the spinal marrow, a cord is produced, which reaches to the os coccygis, and there splits into threads, which may be considered as the termination of the last teeth of this ligament.

LIGAME'NTUM FALLO'PII. See LIGAMENTUM POU-PARTII.

LIGAME'NTUM HE'PATIS SUSPENSORIUM, the remains of the umbilical vein.

LIGAME'NTUM INTERMAXILLA'RE. A ligament on each side of the face, which connects the two jaws, and receives the posterior fibres of the buccinator muscle. (Winslow.) It is strong and broad, fixed to the outside of the upper jaw, above the last dens molaris, and at the side of the apophysis pterygoidæus internus. By the lower end it is fixed on the outside of the lower jaw, below the last dens molaris.

LIGAME'NTUM LATUM, OR SUSPENSO'RIMUM HEPATIS, is made up of the double membrane of the peritonæum, which covers the liver on each side, and meets to be joined by the sternum.

LIGAME'NTUM POU'PARTII, OR FALLO'PII. POU-PART'S LIGAMENT. It is only the lower border of the descending oblique muscle of the belly stretched from the fore part of the os ilium to the pubes.

LIGAME'NTUM PU'BIS INTEROSSEUM, is a strong triangular ligament, fixed by two of its edges in the inferior branches of those bones, all the way up to their common symphysis; the third edge, which is lowest, is loose; and this whole membrane, the middle of which is perforated by a particular hole, is stretched very tight between the two bones, and under their cartilaginous arch, to which it adheres very closely.

LIGAME'NTUM ROTU'NDUM. THE ROUND LIGAMENT. One of these is found on each side of the uterus; and each is composed of a plexus of blood vessels upon the fore part of the ligamenta lata, running in the duplication of these ligaments. From the corners of the fundus uteri, they pass through the annular aperture of the obliquus externus, and are lost in the middle and upper part of the fat in the groin.

LIGAME'NTUM SUSPENSO'RIMUM. See CORPORA CAVERNOSA PENIS.

LIGA'TIO, and LIGATU'RA, (from *ligo*, to bind). A BANDAGE, or LIGATURE (see FASCIA): a stiffness of the joint, and sometimes that impotence supposed to be induced by magic.

LIGATU'RA VE'NERIS. Camphor, which is supposed to check the venereal appetite. See CAMPHORA.

LIGNUM, (from *lego*, to gather). WOOD; because its branches are gathered into bundles for domestic use; a term applied to many medical substances; as, LIGNUM ALOES, LIGNUM GUAIAICUM, LIGNUM QUASSIA, &c. vide in verbis.

LIGNUM CAMPECHIA'NUM. See CAMPECHENESE LIGNUM.

LIGNUM COLUBRI'NUM; *strychnos colubrina* Lin. Sp. Pl. 271. It is of the same genus, perhaps the same species, which affords the nux vomica, and is, like it, intensely bitter and acrid. Like every poisonous substance, it excites the greatest commotions in the system, and is emetic, cathartic, diaphoretic, and anthelmintic, seeming to affect also the intellectual powers. As its name imports, it has been given to those bitten by serpents, to cure intermittents, and to destroy worms.

LIGNUM MOLUCCENSE vel **PAVANÆ.** The seeds of the tree, *croton tiglium* Lin. Sp. Pl. 1426, which affords this wood are called *grana tiglitii*; and these, as well as the wood, are highly acrid, producing the most violent commotions in the whole body, with discharges from almost every excretory. The oil of the seeds is, however, perfectly mild; and the genus is nearly allied to the ricinus which affords the castor oil.

LIGNUM NEPHRITICUM. It is supposed that this wood and the Behen nuts are from the *guilandina maringa* Lin. Sp. Pl. 546. The first is of a pale yellow, though it tinges wood of a fine blue colour; the taste is slightly acrid and bitterish. The nuts are mucilaginous and oily; their oil keeps long without rancidity. It has been used in itch, besides the disease from which its name is derived.

LIGNUM RHODIUM, probably from the *genista canariensis* Lin. Sp. Pl. 997. Much confusion has arisen respecting the real tree from which this wood is taken, in consequence of its being supposed the same with the *aspalathus* of Dioscorides; for the *aspalathus* of Galen was a bark. The *aspalathus* of the moderns was the calambour wood, or the lignum aquilæ, resembling the lignum aloes. The lignum rhodium, at present sold, is in long crooked pieces, full of knots, of a reddish yellow colour. The largest, smoothest, most compact, and the deepest coloured, is preferred. The taste is bitterish, and somewhat pungent. It smells strongly like a rose; and the wood, as well as the oil, is supposed to be sudorific.

LIGNUM SERPENTUM. The wood of the *ophioxylum serpentinum* Lin. Sp. Pl. 1478.

LIGUSTICUM, (from *Liguira*, the country where it flourished). See **LEVISTICUM.**

LIGUSTRICUM. See **SESELI VULGARE.**

LIGUSTRUM, (from *ligo*, to bind, from its use in making bands). **PRIVET.**

LIGUSTRUM I'NDICUM; *alcanna*, *Cyprus Dioscoridis et Plinii*, *elhanne Arabum.* **EASTERN PRIVET;** the *henna* of the Turks and Moors, and *lausonia inermis* Lin. Sp. Pl. 498. It is reckoned emmenagogue, but is little used, except to impart a red colour to the nails of women and the beards of men.

Phillyrea, or mock privet, is said to be an astringent; but, like the rest, is neglected in practice.

LIGUSTRUM VULGARE, *ligustrum Germanicum* **PRIMPRINT,** or **COMMON PRIVET;** *ligustrum vulgare* Lin. Sp. Pl. 10; is a shrub with rough pliant branches, and much used for hedges in gardens; the flowers grow in spikes, and are of a whitish colour, followed by clusters of black berries: they appear in May and June; the berries are ripe in September.

There are other plants of this name reckoned somewhat astringent, and useful in hysteric disorders, but they are never used.

LILIASTRUM ALPI'NUM MINUS, (from *lilium*, the lily, which it resembles). **SPIDER WORT.** *Phalangium allobrogicum*, *anthericum liliastrum* Lin. Sp. Pl. 445. This plant is chiefly used as an ornament in gardens, though it is said to resist poison, and to be useful in relieving cholick.

LILIO HYACIN'THUS, (from *lilium*, and *hyacinthus*, because its roots resemble those of the lily, and the flowers those of the hyacinth). The **LILY HYACINTH.** *Scilla lilio hyacinthus* Lin. Sp. Pl. 442. The roots like those of the lily, promote suppuration.

LILIUM, (from *λεως*, smooth, graceful). The **LILY.**

LILIUM CONVALLIUM MINUS. See **MONOPHYLLON.**

LILIUM A'LBUM. The **COMMON WHITE LILY,** *lilium candidum* Lin. Sp. Pl. 433, is perennial, a native of Syria and Palestine, common in our gardens, and flowers in June. The flower gives an agreeable flavour to expressed oil, and the roots are extremely mucilaginous boiled with milk or water, they are useful in emollient and suppurating cataplasms: but the bread and other farinaceous poultices possess equal advantages. Dr. Alston thinks the roots are of the nature of squills. Godorus, serjeant-surgeon to queen Elizabeth, cured many dropsical people, by giving them bread in which these roots were baked.

LILIUM CONVA'LLIUM convellaria *Maianthemum,* **MAY LILY,** and **LILY OF THE VALLEY,** *convallaria majalis* Lin. Sp. Pl. 451. Its flowers are smaller than any other lilies, have a penetrating bitter taste and a fragrant smell: the bitter remains both in the spirituous and watery extract; and is nearly as purgative as aloes. The dried flowers are a strong sternutatory; and the roots possess the bitter and purging qualities of the flowers. The flowers were formerly used in nervous complaints, sometimes in spasmodic asthmas, or catarrhs.

LILIUM RU'BRUM, *hemerocallis fulva* Lin. Sp. Pl. 462, *lilium furspuracocceum,* *lilium croceum.* **ORANGE LILY.** The leaves are cooling, and the roots aperient and stimulating.

LILIUM PARACELSI, a fanciful term of that enthusiast for a very pungent penetrating alkaline tincture.

LIMACES. **SNAILS.** The common garden snail; *limax agrestis* Lin. Syst. Natur. 1082, is viscid and glutinous, supposed to be highly nutrient, and employed sometimes, seemingly with advantage, in hectic. The gluten of the *l. maximus cinereus* L. 1081, is used as a resolvent liniment in glandular tumours. See **MOLLUSCA.**

LIMATU'RÆ FE'RRÆ, (from *lima*, a file). See **FERRUM.**

LIMO'NIUM, (from *λειμων*, a marsh, from its colour,) **SEA LAVENDER;** *statice limonium* Lin. Sp. Pl. 394, is astringent, and said to be given with success in diarrhæas, dysenteries, menorrhagia, and all kinds of hæmorrhages. The roots and leaves are chiefly used. A name also for *behen rubrum* and *beta sylvestris.*

LIMONUM (from *λειμων*, from the green colour of its unripe fruit, or from the Hebrew term *rimon*). The **LEMON TREE;** *citrus medica,* *malus medica* and *fersica* Lin. Sp. Pl. 1100, β, is a native of Asia, but cultivated in the warmer parts of Europe. Linnæus reckons the citrons and lemons to be only varieties of one species, distinguished from the oranges only by the pedicles of the leaves being naked.

The yellow rind of lemons is a grateful aromatic, and very commonly used in stomachic tinctures and infusions, as it conceals the disagreeable flavour of many bitters. It affords an extremely volatile essential oil, of a pale straw colour, in smell as agreeable as the fresh peel, which is employed as a perfume; but often adulterated with spirit of wine, or with oil of turpentine. If it is adulterated with oil of turpentine, on adding a little spirit of wine, the mixture becomes milky; if with spirit, the addition of oil of turpentine has the same effect.

The juice of lemon is more acid than that of oranges: half an ounce of good lemon juice saturates about a scruple of fixed alkaline salt; and this mixture, with the addition of a small quantity of any aromatic water, is useful in relieving nausea and vomiting; especially if taken during its effervescence. It is called the saline draught of Riverius, is cooling, and from this effect promotes perspiration in fevers. The juice often allays hysterical palpitations of the heart, and, in jaundice, four or six ounces taken in a day are highly useful. Its other properties are similar to those of the orange juice. The salt of lemons usually sold is the salt of wood sorrel, the oxalic acid differing, however, but slightly from the citric, and flavoured with the essential oil of lemons. The concrete salt is pure acid separated from the mucilage in the way recommended by Scheele, viz. uniting it with calcareous earth, and separating the acid by means of the vitriolic. As an antiscorbutic, lemon juice is generally taken on board of ships; but it spoils by long keeping, unless a small portion of ardent spirit be added. It is sometimes boiled to the consistence of a rob; but the mucilaginous part is then burnt, which gives a bitter flavour, and the acid is in part decomposed: indeed, for all the purposes of an antiscorbutic the juice must be fresh. See Neumann's Chemical Works; Lewis's Materia Medica.

LINAGRO'STIS, (from *λινον*, cotton, and *αγροστis*, grass; from the softness of its texture). See PANICUM.

LINARIA, (from the resemblance of its leaves to those of flax,) *osiris urinaria*, FLAX WEED, OR COMMON TOAD FLAX, *antirrhinum linaria* Lin. Sp. Pl. 858. The common sort resembles the esula minor so closely, that it cannot be distinguished before the flowers appear but by breaking the stalk, as the toad flax is destitute of the milky juice. It is perennial, grows wild about the side of dry fields, and flowers in June and July. If the leaves, which are bitterish, and of a saline taste, resembling in smell, when rubbed, the elder, are inwardly used, they are diuretic and purgative and particularly powerful in the latter view. The plant has been supposed also an aperient and deobstruent, and used in jaundice. Externally they have been commended against the piles. A name also for a species of *elychrysum*.

LINARIA HEDERA'CEO FO'LIO. See CYMBALARIA.

LINCTUS, (from *lingo*, to lick). *Lohoc eclegma*, *elixis*, *electos*, *illinctus*, LAMBATIVE; a composition thicker than syrup, but softer than an electuary, first made to be licked from a stick of liquorice, and then gradually swallowed. A linctus is usually formed of mucilages, or of oils mixed by means of mucilage, and often slightly acidulated. It is chiefly used in disorders of the inward parts of the mouth, the fauces and œso-

phagus, as in aphthæ, and tickling coughs from deflections of thin serum; but it soon palls.

LI'NEA A'LBA, vel CENTRALIS, (from *linum*, a thread, and *album*, white, from its appearance and colour, or situation). It extends from the os pubis to the cartilago ensiformis, and so high as the navel it is a mere line, but above broader. It is formed by the union of all the tendons of the abdominal muscles, which, by their united action, compress the belly. In this line the trochar, in tapping, is often introduced, and it is divided in hysterotomy, as the wound is attended with but a slight hæmorrhage.

LI'NEÆ SEMILUNARES terminate the lower part of the external oblique muscle of the abdomen, and are lost at the upper part.

LI'NEÆ TRANSVE'RSÆ pass between the linea alba and lineæ semilunares, formed by the tendinous lines of the recti muscles. They are not directly transverse, as often represented, but irregularly waved.

LINEA'TUS, (from *linea*, a line). A leaf whose surface is streaked, with lines.

LINGO'DES, (from *λυγω*, to sound). An appellation of fevers attended with an hiccough.

LI'NGUA, (from *lingo*, to lick). THE TONGUE, *glotta*, *plectrum*. This term is also applied to some vegetable substances, from their similarity in shape to the tongue. In animal bodies it is composed of two parts; the inferior is a mass of muscle; the upper surface is, towards the apex, full of papillæ, which, when traced backward, become more irregular and flat, whence authors distinguish the papillæ pyramidales, capitatae, and lenticulares; but each kind is a mass of vessels running from the basis towards the apex. Near the epiglottis the surface of the tongue is glandular; and near the middle is a chap, called the *foramen cæcum*, first described by Morgagni, and since supposed by Vaterus, without foundation, to be the orifice of salivary ducts. Under the papillæ, on the surface of the tongue, are fleshy fibres running in every direction; to these its great variety of motions is owing: under the tongue is a membranous substance, called *frænum*, or *filetum*; the part next the root is called *cephaline*; the tip, *proglossis*.

LI'NGUA A'VIS. The seeds of the ash so called from their resemblance. See FRAXINUS.

LI'NGUA CANI'NA. See CYNOGLOSSUM.

LI'NGUA CERVINA, *calcifraga*, *phillitis scolopendrium*, *asplenium scolopendrium* Lin. Sp. Pl. 1537. HIND'S OR HART'S TONGUE, is a plant with long, uncut, narrow leaves, of a bright green colour, standing on long hairy pedicles, without any stalk or manifest flowers: the seeds are a fine dust, lying in large, rough, brown, transverse streaks on the backs of the leaves. The plant is perennial, found green every season, delighting in moist, shady, stony places. The leaves are commended as aperient and corroborant, particularly in diseases of the viscera; but not at present employed.

LI'NGUA SERPE'NTIS. See OPHIOGLOSSUM.

LINGUA'LES, (from *lingua*, the tongue). The ninth pair of nerves. See HYPOGLOSSI EXTERNI.

LINGUA'LES GLA'NDULÆ; those at the basis of the tongue. See LINGUA.

LINGUA'LIS MU'SCULUS. THE MUSCLE of the TONGUE, rises from the basis of the os hyoides, and runs to the tip of the tongue. It consists in general of fleshy fibres, which run in many directions; but

those fibres chiefly distinguished by this appellation turn the tongue laterally and downwards.

Mr. Home has shown, that the tongue is by no means an irritable muscle, and that any part of it may be cut off with little danger.

LINIME'NTUM, (from *linō*, to anoint). **LINIMENT**, *hyfaleipton*, *litus*, *perichrasis*, is a thin ointment, and principally designed for an application where the tenderness of a part will not admit of a hard one. Sometimes the term is applied to an application almost fluid; but when it approaches this state the appropriate application is a *wash*. The minute precision of the ancient pharmaceutists is now, however, often disregarded.

LINIME'NTUM A'LBUM. See **SPERMACETI**.

LINIME'NTUM ARCÆ'I. See **ELEMI**.

LINIME'NTUM BITU'MINIS AMMONIATUM. R. *Petrolei Barbadosis* ℥ i. ss. aquæ ammoniæ puræ ℥ ss. m. This is a strong stimulant, applied in diseases of the hip.

LINIME'NTUM CA'MPHORÆ COMPO'SITUM. R. *Camphoræ* ℥ ij. olei olivæ ℥ i. aq. ammon. puræ ℥ iij. m. in oleo prius solvatur camphora, deinde adjiciatur aqua ammoniæ puræ; an application of use in deep seated inflammations, and to hasten suppuration.

LINIME'NTUM CA'MPHORÆ AMMONIATUM. R. *Spiritus camphorat.* ℥ ij. aquæ ammoniæ puræ ℥ ij. m. used in chronic enlargements of the joints, and other affections, which require the use of external stimulants.

LINIME'NTUM CERU'SSÆ CUM SAPO'NE. See **PLUMBUM**.

LINIME'NTUM OLEO'SUM. See **AMBUSTA**.

LINIME'NTUM SAPONA'CEUM, *linimentum saponis*, formerly called *opodeldoc*, and saponaceous balsam, and chiefly employed for external purposes in rheumatic pains, sprains, and bruises. The London college directs the following very liquid form, because the soap acts more advantageously when diluted.—Take of the spirit of rosemary, ℥ i.; hard Spanish soap, three ounces; camphor, one ounce; digest the soap in spirit of rosemary until it is dissolved, and add to it the camphor. Ph. Lond. 1788. See **OPODELDOC**.

LINNÆA, *borealis* Lin. Sp. Pl. 880. Its leaves are bitterish and substrigent. They are employed in decoction as a fomentation in rheumatism, and the infusion in milk has been recommended in sciatica.

LINO'SYRIS, (from *λινος*, *flax*). An herb whose leaves resemble those of flax. See **ELICHRYSUM**.

LINQUART. See **DISCESSUS**.

LINTEUM, **LINT**, (from *linum*, *flax*; of which it is made). When lint is used in a flat oval form it is called a pledget; when cylindrical, a dossil. It is used as a medium for applying ointments, to stop hæmorrhages, and, in the form of a dossil, to prevent wounds from closing. When merely to defend wounds is required, poultices are now preferred to lint. See **CARBASUS**.

LINUM, (from *λειος*, *soft*, *smooth*; from its smooth texture). **FLAX**. *Linum usitatissimum* Lin. Sp. Pl. 397, is properly called *line*, only while standing green in the field, without any inner bark: when the inner bark is perfected, it is called flax.

Line, or lintseed, is of a reddish brown colour, glossy, flat, slippery, nearly oval, and pointed, with an unctuous, mucilaginous, sweet taste, but no smell. On ex-

pression much oil is obtained from it, which, if drawn without heat, is insipid, but does not congeal with the winter's cold, nor form a solid soap when mixed with alkalis, but acts more powerfully than any expressed oil as a menstruum on sulphureous bodies. When this oil is sweet it is emollient; when rancid, it is said to be more powerful as an expectorant. It is supposed to be more healing than the other oils of this class, and consequently more often employed in pulmonary complaints, in colics, and constipations of the bowels. In burns and scalds, and when women's breasts are inflamed from the milk stagnating in them, it affords considerable relief. If the seeds are boiled in water, they afford a large quantity of mucilage; but if designed for internal use, an infusion is more agreeable. Infusions of lintseed are emollient and demulcent, of use in tickling coughs, stranguries, &c. A spoonful of the seeds unbruised is sufficient for a quart of water; but liquorice root is often added, and, with the addition of colt's foot leaves, it is called the *pectoral infusion*.

The mucilage obtained by inspissating the decoctions is an excellent addition for reducing powders of an unpleasant taste into the form of an electuary. The seeds may be used for promoting the digestion of abscesses after the oil is expressed from them; but such applications are generally made by stirring a sufficient quantity of the meal into boiling water to form it of a proper consistence. A cataplasm of this kind is esteemed as an emollient; but the lintseed meal alone is so mucilaginous that it requires the addition of some soft bread to adapt it for this purpose. See **Lewis's Materia Medica**.

It is the name also of some of the finer species of **AMIANTHUS**, q. v.

LINUM CATHARTICUM, Lin. Sp. Pl. 401, *linum minimum*, *chamælinum*, **MOUNTAIN FLAX**, **MILL MOUNTAIN**, and **PURGING FLAX**, is a small plant, with little, oblong, smooth leaves, having one rib running along the middle. The stalk is slender, reddish, divided towards the upper part into fine branches, bearing on the tops white flowers, followed, as in the common flax, by roundish ribbed capsules, with ten flattish unctuous seeds in each. It is annual, and grows wild on chalky hills and dry pasture grounds; is an effectual, safe purge; for which purpose a handful of the fresh leaves infused in wine or whey, or a drachm of the leaves in powder, is sufficient. See **Raii Historia**; **Lewis's Materia Medica**.

LIPARIS, (from *λιπος*). **FAT**.

LIPAROCÉLE, (from *λιπος*, *fat*, and *κηλη*, *a tumour*). Any tumour containing a fatty substance.

LIPODE'RMUS, (from *λειπω*, *to leave*, and *δερμα*, *the skin*). See **PRÆPUTIUM**.

LIPOMA, (from *λιπος*, *fat*). An indolent, fatty tumour, often fluid in the centre.

LIPOME. See **NÆVUS**.

LIPOPSY'CHIA. See **LEIPOPSUCHIA**.

LIPOTHY'MIA; **LEIPOTHY'MIA**, (from *λειπω*, *to leave*, and *θυμος*, *the mind*). **FAINTING**. *Deliquium animi*, *defectio*, *exanimatio*, *syncope*, *asphyxia*; *virium lapsus*; in a greater degree, *apopsychia*, and *echysis*; *syncope* of Dr. Cullen, who places it in the class *neuroses*, order *adynamia*; defining it the motion of the heart diminished, or at rest for some time. The species are, 1. *Syncope cardiaca*, when it often returns without any evident cause, with violent palpitations of the heart at

intervals; from some fault of the heart, or contiguous vessels. 2. *Syncope occasionalis*, when it arises from a manifest cause, from an affection of the whole system. Each is styled idiopathic: the symptomatic species are, *syncope febrilis, exanthematica; stomachica; hysterica; arthritica; scorbutica*. The ancients named it *cardia*, when caused by anger: and what we termed syncope they called *CARDIACA PASSIO*, q. v.

In this disease the pulse and respiration become suddenly weaker than usual, and, to the perception of the attendants, seem often wholly to cease. In its slightest degree the patient constantly perceives and understands, without the power of speaking; and this often happens to those who are disturbed with flatulencies, without any remarkable alteration in the pulse.—If he loses his feeling and understanding, with a considerable sinking of the pulse, it is called a *syncope*. If so violent that the pulse seems totally to have ceased, without any discernible breathing, and a manifest coldness of the whole body, with a wan livid countenance, it is sometimes followed by death, and called an *asphyxy*, or a total resolution. This last degree, in most instances, constitutes, according to Dr. Cullen's arrangement, varieties of apoplexy, and these chiefly of the species which he calls *venenata*.

The causes are either an excess or a deficiency of blood, a loaded or disordered stomach, violent pains, nervous complaints, passions of the mind, a polypus in some of the principal blood vessels, and opiates, or active deleterious medicines, or effluvia.

The different degrees of this disorder should be distinguished from hysteric fits, epilepsy and the apoplexy. In the two former diseases there are generally spasms; in the latter the breathing continues, and is laborious, or stertorous. When either disease is without these appropriate symptoms it becomes syncope, or distinction is of little importance, as the remedies are the same.

Those subject to frequent faintings, without any manifest cause, usually die suddenly, and polypi are found in the large blood vessels. When anger, in weak persons, or worms, is the cause, the disease is dangerous.

During the fit, cold water, or vinegar and water, may be sprinkled on the face, and a little of the same poured down the throat. Strong vinegar, or volatile spirit, may be held under the nostrils, the extremities well rubbed, and, as soon as the power of swallowing returns, a glass of wine, brandy and water, of fetid tincture, or of the spirit of hartshorn with water may be given.

When the fit is over, the cause must be diligently examined, and the morbid state of the system, from which it seems to arise, will determine the plan of treatment. When no distinct cause can be assigned, when the face is livid, and the breathing difficult; when the left hand is cold, and the patient cannot be easy on either side; when it is brought on by extraordinary exertions, by exercise, or whatever increases the circulation through the lungs, we have much reason to fear that it proceeds from an affection of the heart. This is sometimes an enlargement of its cavities, or its contiguous vessels; sometimes an accumulation of water in the pericardium or lungs, or ossifications of the valves. In such circumstances medicine is of little avail. Small bleedings, easy laxatives, camphor, with nitre, and

whatever lessens the impetus of the blood, are advantageous. The most perfect repose of body and mind, the mildest food, and the most cooling liquors, are necessary. A blister from some part of the chest has also been found of service.

It often happens, however, that syncope arises from fulness of the stomach and bowels, and, in the greater number of cases, emetics, with repeated laxatives, will succeed. These, at least, should be tried before the patient is alarmed with apprehensions of a topical affection of the heart.

Excess or deficiency of blood are obvious causes, and easily removed, at least for a time; but one less within our power is that general mobility of the system where every excitement is followed by a proportional sinking. Tonics and cold bathing will have some effect; but the cure is only found in the torpor of advancing years. See *ASPHYXIA*.

LIPPITU'DO, (from *lipfus*, *blear eyed*). See *EPIHORA* and *XEROPHTHALMIA*. Celsus means by it an ophthalmia.

LIQUEFACTIO. *MELTING*. The fluidity of a body when exposed to heat, probably from the combination of caloric. Though we know bodies permanently æriiform, we know none permanently fluid, except alcohol and ether; and those are apparently such, because they have not been exposed to the requisite degree of cold. It is not necessary to liquefaction that the body wets; for this effect is owing to the greater attraction of the fluid particles to the body than to each other. Quicksilver is fluid, but does not wet. Melted lead does not adhere to a polished iron immersed in it.

LIQUIDA'MBAR, (from *liquidus*, and *ambar*). *Styrax liquida, acer virginianum odoratum, liquidambar stiraciflua* Lin. Sp. Pl. 1418, is a resinous juice, of a yellow colour, inclining to red; about the consistence of turpentine; by age hardening into a brittle resin. It is moderately warm and pungent, but rarely met with genuine, and chiefly used as a perfume. See Lewis's *Materia Medica*.

LIQUIRI'TIA, (from *liquor, juice*; or the Welch term *elikoris*). See *GLYCYRRHIZA*.

LIQUOR CYRENIACUS. See *BENZOINUM*.

LIQUOR ÆTHEREUS. See *ÆTHER*.

LIQUOR CERERIS. See *ALLA*.

LIQUOR METALLICUS. See *ARGENTUM VIVUM*.

LIQUOR SALIS. See *CIRCULATUM*.

LIQUOR VENERIS. See *ÆRUGO ÆRIS*.

LIQUOR A'MNII, in midwifery called the *WATERS*, is the fluid in which the fœtus swims during gestation. The quantity of this fluid is different in different women, and in the same woman in different pregnancies. It is largest in the earliest months, and when the mother is past the prime of life, or the child is weak. At parturition the *waters*, as they are called, exceed two quarts, and sometimes scarcely two ounces. There are, occasionally, what are styled false waters, which are frequently discharged at different periods of pregnancy; but if the amnios be really ruptured, labour is inevitable. It is now admitted that this fluid is exhaled from the vessels of the fœtus, and does not contribute to its nourishment. See *FÆTUS* and *AMNION*.

LIQUOR MINERALIS ANODYNUS HOFFMANNI. Hoffman, the inventor of this medicine, highly extols it

as an anodyne and antispasmodic. In the Paris Pharmacopœia the following formula is given; but it is not certainly known to be that which Hoffman employed, as he never revealed it.

Hoffman's mineral anodyne liquor.—To one pint and a half of highly rectified spirit of wine, placed in a large glass retort, pour, by little and little, through a long stemmed glass funnel, half a pound of concentrated oil of vitriol. Stop the mouth of the retort; digest for some days; and then distil with a gentle heat. At first a fragrant spirit of wine will arise, and after it a more fragrant volatile spirit, which is to be caught in a fresh receiver: the receiver being again changed, a sulphureous volatile acid phlegm comes over; and, at length, a sweet oil of vitriol, which should be immediately separated, lest it be absorbed by the phlegm. Mix the first and second spirits together; and, in two ounces of this mixture, dissolve twelve drops of the sweet oil just named. If the liquor hath any sulphureous smell, re-distil it from a little salt of tartar. This liquor is a mixture of what is styled the *sweet* spirit of vitriol, ether, and the oleum vini; a preparation not very different, probably, from the ether of Tickel. It is imitated in the London Pharmacopœia, by adding three drachms of the oleum vini to two pounds of ether; and that of Dublin orders it to be prepared by drawing over one half of the residuum, after the vitriolic ether is separated. It is given as a sedative, and antispasmodic, in hysteric, arthritic, and other painful complaints; to adults from thirty to an hundred drops, or more, with some sugar, or in an appropriate mixture. See ÆTHER.

LITHAGO'GUS, (from λιθός, a stone, and ἀγω, to bring away). An epithet for a medicine that expels the stone.

LITHA'RGYRUM, (from λιθός and ἀργύρος, silver). LITHARGE; *lithargyrum auri, almakanda, almakarb, chrysis, chrysis spodos; cycima; calciteosa, argyritis; cathmia*. Litharge was usually prepared from the lead employed in refining silver; and it was of a deep yellow, or of a whitish colour, according to the different bodies mixed with it, or according to the different degrees of heat to which it was exposed. If its colour is dark it is called litharge of gold, *alatum*; if light, of silver, *almarcarida*. This method, however, is not sufficient for the supply; and it is often prepared by melting oxidized lead by a hasty fire. There are a very great variety of medical compositions, of which litharge, or some of its preparations, make the principal, and always a material, ingredient.

LITHA'RGYRI ACETA'TI A'QUA, (see PLUMBUM), is made by dissolving two pounds, four ounces of litharge in a gallon of distilled vinegar, by boiling to six pints.

LITHA'RGYRI ACETA'TI CRE'MOR. See PLUMBUM.

LITHA'RGYRI COMPOSITA AQUA. See LOTIO HYDRARGYRI ACETATI.

Ceratium saponis is, strictly speaking, a preparation of litharge, and is made by boiling a pound of litharge with a gallon of vinegar over a slow fire, constantly stirring it till it thickens; then adding ten ounces of yellow wax, eight ounces of soap, and a pint of olive oil.

Collyrium lithargyri acetati.—1. Let ten drops of

the water of acetated litharge be added to four ounces of rose water; 2. To the above let twenty drops of camphorated spirit be added; but mix the spirit with the acetated litharge before the water, which must be added afterwards, to prevent the camphor from separating.

Linimentum lithargyri compositum.—R. Unguenti lithargyri cum aceto ℥ss. camph. gr. viij. cerussæ acetatæ gr. xvi. opii pulverizati gr. viij. m. with this the inflamed edges of the eye lids are sometimes ordered to be anointed at bed time.

Lotio lithargyri acetati camphorati. See AMBUSTA.

Emplastrum lithargyri. See EMPLASTRUM COMMUNE, and EMPLASTRUM.

Lotio lithargyri acetati, is made by adding one ounce of rectified spirit of wine, to two pints of distilled water, mixed with two drachms of the water of acetated litharge; two drachms of proof spirit, added to the same quantities of the other ingredients, forms the aq. lithargyri acetati composita of the London Pharmacopœia.

Cataplasmæ lithargyri acetati. See PLUMBUM.

Ceratum lithargyri.—R. Emplastri lithargyri; adipis suillæ āā ℥iv. ceræ flavæ ℥ss. colliquantur, et quando fere frigida fiat mixtura, adjiciantur aquæ lithargyri acetati ℥ij. agitentur simul donec frigescant. For superficial sores, or ulcers whose edges are inflamed, this application is much recommended.

Unguentum lithargyri acetati, made by adding half a drachm of the aqua lithargyri acetati to an ounce of unguentum ceræ, is applied to small ulcers, whose edges are in a state of inflammation, and preferred to the unguentum cerussæ acetatæ, because it is more readily made, and does not soon grow rancid. See NUTRITUM UNGUENTUM.

Unguentum lithargyri compositum.—R. Emplast. litharg. lb ss. adipis suillæ pp. ℥iv. olei olivæ, unguenti ceræ, āā ℥vi. aceti uncias quatuor; aquæ lithargyri acetati ℥ij. After the unctuous ingredients are melted together and suffered to cool, the water of acetated litharge, and the vinegar, are to be gradually incorporated. This ointment is applied with great effect in inflammations of the skin.

Ceratum lithargyri acetati.—Take water of acetated litharge, two ounces and an half by measure; yellow wax, four ounces; olive oil, nine ounces by measure; camphor, half a drachm: rub the camphor with a little of the oil: melt the wax with the remaining oil; and, as soon as the mixture begins to thicken, pour in by degrees the water of the acetated litharge, and stir constantly till it is cold: then mix the camphor previously rubbed with oil. Ph. Lond. 1788.

LITHI'ASIS, (from λιθος, a stone). The GRAVEL or STONE; more commonly the disposition to this disease. (See CALCULUS and ADAMITA.) Also a tumour on the eye lid, containing a hard concretion between its coats.

LITHIAS, (from λιθος a stone). LITHIAT. Salt formed by the union of the lithic acid, or acid of the calculus and different bases.

LITHODE'NDRON, (from λιθος, and δένδρον, a tree). CORAL; from its resembling a petrified branch. See CORALLIUM.

LITHOEIDES, (from λιθος, and εἶδος, form; from its hardness). See TEMPORUM OSSA.

LITHONTRI'PTICUS, (from *λίθος*, a stone, and *θρῆνω*, to break). An appellation of medicines supposed to break or dissolve the stone in the bladder; *calculifragus*. Though the different stones generated in the human bladder may require different solvents when out of the body, and though art has not yet afforded a medicine, which, when injected into the bladder, will, without injury, dissolve the contained stone, we must not conclude that no medicine has this power, when taken into the stomach, for the solvents already mentioned (see **CALCULUS**) certainly produce some effect on the urine; and more powerful ones may be found, which will destroy the stone, without hurting the human body. The water into which the boiled white of egg melts will liquefy myrrh, but will give no uneasiness to the eye.

We have spoken already of the greater number of lithontriptics, particularly the alkalis and the bitters, which act, as we have said, by checking the acidity in the stomach, on which the formation of calculus appears to depend. To the authorities before quoted, that the alkali penetrates with undiminished properties to the bladder, or at least with properties which arise from its union with the lithic acid, we may add, that of professor Mascagni, of Sienna, supported by that of Hufeland. The pure kali, it is remarked, may be taken in the quantity of a drachm daily, in a pint of veal broth, or a quart of pure water; and the carbonated kali in three times that dose. The liquor lithontripticus Loosii consists of a drachm of muriated lime dissolved in two ounces of pure water, of which thirty drops are to be taken four times a day, and the dose increased as the stomach can bear it. The aerated water, viz. water combined with carbonic acid gas, or with carbonated alkali and this gas, in excess, have been often used with success as lithontriptics.

LITHOPHY'TON, (from *λίθος*, a stone, and *φυλον*, a plant). A **LITHOPHYTE**, *keratophytón coral*; a species of plant of a horny substance, seeming to be of a middle nature betwixt wood and stone.

LITHOPHY'TON NIGRUM. See **CORALLIUM NIGRUM**.

LITHOSPE'RMUM, (from *λίθος*, and *σπερμα*, semen; from the hardness of its seed). *Milium solis*, *Ægonychon*, *ctonychum*, **GROMWELL**, **GRAYMILL**, **LITHOSPERMUM OFFICINALE** Lin. Sp. Pl. 189, is a rough plant, with stiff branched stalks, oblong acuminate leaves, set alternately without pedicles, and whitish monopetalous flowers, scarcely longer than the cup, followed by roundish hard seeds. It is perennial, grows wild in fields, and flowers in May and June. The seeds are diuretic; but rarely used. See Lewis's *Materia Medica*. It is also a name for the *lacryma Jobi*.

LITHOTO'MIA, (from *λίθος*, a stone, and *τεμνω*, to cut). *Cystotomia*. **LITHOTOMY**, or cutting for the stone.

This operation was performed in the time of Hippocrates, but confined to one family; and, in the oath to be taken by practitioners, this operation is forbidden, apparently, because those to whom so delicate an incision was familiar would perform it more dexterously. The method employed we shall soon describe as that with the "lesser apparatus." This method was improved in the sixteenth century, by Joannes de Romanis, whose operation was styled that with the

"greater," as it was a more complicated "apparatus." It is described by Marianus Sanctus, who wrote so clear and comprehensive a description of the operation, with the parts concerned, that it includes every method of opening the bladder, and very plainly hints at the improved lateral method. The high operation was first proposed by Franco, a French surgeon, in the same century. The various inconveniences which attended each rendered the attempt uncommon, till a French priest, Frere Jacques, probably catching the hint from Marianus, attempted the lateral method; which, though unskilled in operations, and indifferently provided with instruments, he executed with a success which excited the applause of the world, the indignation, and, at last the emulation, of the faculty. Various improvements have been since made, which we shall notice in their place.

We have already spoken of the symptoms of **CALCULUS**, vide in verbo, nor need we add to them, since the ultimate decision depends on the sound. This is, in fact, a part of the operation.

When a stone is suspected to be lodged in the bladder, and a fuller examination is necessary, an instrument called a **SOUND** is introduced into the bladder, if possible, to feel the stone. For this purpose, Mr. Sharp directs "the patient to be laid on an horizontal table, with his thighs elevated, and a little extended: the sound, previously warmed and oiled, is then passed, with the concave part towards the operator, until it meets with some resistance in the perinæum, a little above the anus: it must then be turned without much force, pushed gently on into the bladder; and if it meets with an obstruction at the neck, its extremity is raised upwards, by inclining its handle. If it do not then slip in, it should be withdrawn a quarter of an inch, the fore finger introduced into the rectum, and the point lifted up, which will facilitate its admission." See **CATHERISMUS**.

When the sound enters the bladder, it must be moved round in every direction. It sometimes at once strikes against the stone, and by no artifice is the stone again found. Sometimes none meets the instrument. As its weight may drag the bladder down on the rectum, the finger should be introduced into the gut, and that part of the bladder raised, or the body should be moved into different positions. We have remarked, that in discovering a stone we are more often indebted to chance than to skill; but, if once found by an experienced surgeon, the operation may be performed. We say by an experienced surgeon, since it is said that pieces of sand may strike against the catheter, and give the sensation of a stone. This, however, will not mislead a person who has once felt it. The sensation imparted by the instrument is not decisive of the size of the stone; and a small stone is often as readily found as a large one: but if inclosed in a sac, or if adhering to the bladder, the wrinkles of the inner coat defend it, and the sound will not detect it. If the patient uses some exercise before the search, it may detach the stone from slight adhesions.

After the operation, children relapse more frequently than adults; and adults run greater hazards in the operation than children.

The method employed from the first attempts to

extract the stone has been called the Celsian, sometimes the Guidonian, operation, cutting upon the gripe, or with the lesser apparatus. This operation will appear to be an obvious one; but the term apparatus is improper, since it only requires a common scalpel, and occasionally a hook. The child, for it is confined to children, though Paulus of Ægina observes, that he has practised it in a more adult age, is held in an oblique position, and the finger, introduced into the rectum, is employed in pressing the stone forward against the perinæum, and confining it. The operator then cuts on it, and extracts it, assisting the extraction, if large, with the hook. Heister tells us, that he continued to employ this mode of operating in young subjects. The operation was too simple, perhaps, for modern refinement, but it had also some inconveniences. It was not easy to find the stone from the rectum, or to confine it against the perinæum, for the time necessary to extract it. The operation also was confined to young subjects, where the parts were thin, and the pressure of the stone against the very sensible bladder was often followed by mortification.

The method of De Romanis, or with the greater apparatus, was suggested by the facility with which stones are extracted from the female bladder, in consequence of the greater size of the urethra, and its running in a less curved direction. He supposed that if the urethra in men could, by any operation, be so far curtailed, as to resemble this canal in women, the operation would be equally easy. This method was discovered about the year 1520, but not publicly described by Marianus till fifteen years afterwards. We are expressly told, that the urethra must be divided from a little above its curvature, till the incision reaches the curvature. Then the urethra is strait and dilatable. It is consequently dilated by proper instruments, and the stone extracted. The plan appears plausible, but it seems, on the whole, impracticable to extract a large stone in this way; and we are led to suspect that De Romanis, under the pretence of dilating the urethra, really divided the neck of the bladder. Whether he was aware of this division, and dared not direct it, since Hippocrates had spoken of wounds in the bladder as fatal, Aphor XVIII. lib. vi., and Celsus had repeated the observation, V. xxvi. or that it was an accident which accidentally followed, is uncertain. Le Dran, however, found, on dissection, that, in almost every instance, the neck of the bladder was split or divided; and Falconet, with other authors, have contended, that this division was intended, though dilatation only was described.

The inconveniences of this operation are too obvious to be detailed. Were dilatation only meant, the effect of this violent and continued distention would be incontinence of urine. Were laceration, as must be very often the case, to take place, mortification would generally ensue, and such we find was frequently the consequence. At least, the greater number of patients died; and these fatal events gave an importance to the improvement first attempted by Frere Jacques. But one other operation was previously suggested.

Peter Franco, already mentioned, operating on a child of two years old, found the stone too large to be removed through the wound; accident suggested the possibility of opening the bladder above the pubes,

which he effected, and extracted the stone with success. Yet alarmed, apparently, at his own temerity, he never repeated the attempt, and dissuaded his followers from the operation. Even candour might suggest that he really failed; but, when it was recollected that, just above the pubes, the peritonæum did not cover the bladder, and that, of course it might be opened, without opening the cavity of the abdomen; when to this was added, that the bladder, when dilated, rose far above the pubes, and that a wound might be safely made of an extent to extract any stone which might be contained in that cavity; it did not appear to be a very extravagant attempt. In fact, after Hildanus, Riolan, Dionis, and others, had given a reluctant consent to the trial, and admitted its safety, it was often attempted, before it was publicly recommended, by James and John Douglass, and practised by the latter, by Heister, by Cheselden, and others, in the former part of the eighteenth century.

There are many objections to this method; but, on again going over the subject in the original authors, for the purposes of this short history, we were surprised to find them so few and inconsiderable. It is certainly not necessary to distend the bladder very considerably; yet, on the whole, it is expedient to do so, and to retain the urine for a time longer than usual, several days previous to the operation, to give the bladder greater facility of distention. The distention need not, however, be so great as to injure its tonic power. The operation indeed, for reasons which we cannot explain, has not usually succeeded, when the patient has exceeded the age of thirty, or in those whose bladders are small. When the kidneys are diseased also, it is said that the modern method succeeds better. A singular and unexpected inconvenience, however, which the advocates of this operation endeavour to elude, is the difficulty of healing the wound. The muscular fibres of the bladder are circular, more thick and strong round the sphincter, in fact, thus forming the sphincter itself. When the distention of the bladder, therefore, excites the action of its fibres in general, the resistance is less at the wound above than at the sphincter below; and, indeed, it is so little at the wound, that when the high operation has followed, at the interval of a day, the puncture through the perinæum, the urine is discharged above. The dressings are, therefore, constantly wet, and the wound soon becomes fistulous.

But whatever may have been the advantages or inconveniences, they have all yielded to the operation proposed by Frere Jacques, whose name it has been said was Beaulieu, and who came to Paris in 1697, from the provinces, destitute of money, clothes, and victuals. He was of an open, ingenuous temper, great simplicity of manners, requiring only what would repair his instruments and mend his shoes. His operation is that which we shall soon describe as the *lateral*, but his instruments were coarse, often a razor, or a common penknife; his manner rash and violent, without any fixed plan, or any knowledge of the anatomy of the parts. He soon lost his credit at Paris, and repaired to Holland, where he scarcely succeeded better; but we find him in Germany, fifteen years afterwards, greatly improved, and very successful. It is said, that he had been the servant of an itinerant practitioner,

from whom he had learned the art, which, from want of anatomical knowledge, he was unable at first to practise with advantage.

The physicians of Paris, though they did not treat the good friar with much candour, artfully availed themselves of his hint. The same operation was supported by Meri, but first practised by Mareschal. The lateral operation was soon improved by Rau of Amsterdam, by Heister, and Cheselden; and, in its present state has superseded the three former. On this account we have not described them more particularly; but it was necessary, in giving a general view of the subject, to notice the attempts and errors of others. If our readers derive from this comprehensive sketch as much entertainment and improvement as the author has done, they will not regret the little time they will have employed in the perusal.

The lateral operation is described by Mr. Sharp in the following words from Mr. Cheselden: "The patient being laid on a table, with his hands and feet tied, and the staff passed, as in the old way, let your assistant hold it a little slanting on one side, so that the direction of it may run exactly through the middle of the left erector penis and accelerator urinæ muscles; then make your incision through the skin and fat, very large, beginning in one side of the seam in perinæo, a little above the place wounded in the old way, and finishing a little below the anus, between it and the tuberosity of the ischium. This wound must be carried on deeper between the muscles, till the prostatae can be felt, when searching for the staff, and fixing it properly if it had slipped, you must turn the edge of the knife upwards, and cut the whole length of that gland from within outwards, at the same time pushing down the rectum with a finger or two of the left hand, by which precautions the gut will always escape wounding; after this, introduce the forceps to take out the stone. After the operation is ended, if there is an hæmorrhage from the prostate gland, a silver canula of three or four inches long, covered with fine rag, may be introduced into the bladder, and left there two or three days; for it rarely fails to check it:—the patient may also take an opiate. If the wound does not bleed, a little dry lint, or a pledget of digestive, may be laid in it. If a pain is felt near the bladder soon after the dressings are finished, a bladder of warm water may be applied over it; and if it increases, as there will be much danger therefrom, bleeding and clysters will be necessary."

The present improved practice demands, however, a minuter detail. When a stone has been discovered by the sound, and the operation is determined on, every source of irritation must be removed. The patient, if plethoric, should be bled, the bowels emptied by mild, but sufficiently active, laxatives, interposing a dose or two of calomel, and giving some doses of helleboraster to evacuate worms, should any be present. The warm bath and opiates are advised occasionally, but are apparently unnecessary. The diet should be light and mild, and diluent liquors drunk freely. It is recommended that the bladder be moderately filled previous to the operation, that, in the incision, the exterior part only should be wounded: but as the incision is made on the staff, this appears to be an useless refinement.

The patient is placed on a table, about three feet high, and bends forwards so as to take each foot in the corresponding hand; the wrists and ankles are respectively confined by a broad tape. The buttocks are then, by pillows, raised above the shoulders, and brought forward a little beyond the table.

The sound is introduced, and the stone again sought for. If it was before certainly discovered, though it should not be at this time found, the operation generally proceeds; but if the slightest doubt existed in the previous searches, and it cannot now be felt, a prudent surgeon will defer the operation. If it be determined to proceed, the surgeon makes an incision from the symphysis of the pubes, just below the scrotum, downwards and outwards to the part between the anus and the tuberosity of the ischium, a little below the basis of the process. His next incision he carries nearer the raphe and anus, to avoid dividing the pudica. He thus divides the transversalis penis and part of the levator ani, so as to enable him to feel the prostate. He must guard against cutting the crura penis, which he can easily feel, and the rectum, which is best secured by introducing a finger into it.

He must now feel for the grooved staff, which his assistant must keep against the side of the raphe, by pressing its handle back against the right side of the patient's abdomen. The operator must find the staff steadily opposed to him, from the bulb of the urethra to the prostate gland, and on this he must cut, from below upwards, till the staff can be felt perfectly bare, and the incision will admit the finger, which not only keeps the parts stretched, but guards the rectum from injury.

The next step is to divide the prostate gland and the neck of the bladder. This is sometimes performed by the knife, but the gorget, or, as the French call it, the gorgeret, is employed for the purpose. Its beak is fitted to the groove of the staff, and along it this hollow conical instrument was forced into the bladder, tearing in its passage the neck of the bladder and the prostate, till Mr. Hawkins bent the edges a little more outwardly, and gave them an edge. This *cutting gorget* is now preferred. As the groove in the staff is continued to its end, the beak of the gorget slides easily off; and this part of the operation is so nice and important, that the operator usually chooses to manage both instruments himself.

When the gorget is in the bladder, the urine flows out, and the operator usually attempts to feel for the stone with his finger. Whether he can discover it or not he introduces the forceps, and attempts to take hold of it; opening the forceps when he perceives them touch the stone, and cautiously sliding a blade under the stone, the other is of course over it. The forceps are rough at the hollows, and finely polished between these and the rivet, so that if the stone comes near the latter, it slides to the former. The operator must hold the stone with sufficient firmness to prevent its sliding, but not so closely as to break it, if brittle, and must extract it slowly and steadily. In general, one blade of the forceps should be under the symphysis of the pubes, and the other obliquely below. When the stone is small, it often falls below the line of the instrument; and, in this case, some operators recommend bent forceps, but it is better to introduce the finger

into the rectum to raise the stone, for by the bent forceps the bladder is often injured. Should the blades of the forceps appear distant, it is probable that the stone is large, or that it is held disadvantageously. The last is most frequently the case, and the operator should therefore loosen his hold in order to take it in a more convenient position. It has scarcely ever happened that the stone is too large to be extracted, if drawn forward cautiously, assisted by the finger. Should it slip and fall back at the edge of the wound, the sound and the gorget must be again introduced to guide the forceps.

If the stone is broken, the larger pieces should be extracted by the forceps, and the smaller with a scoop. Afterwards warm water is to be injected, and the patient raised to an upright posture. We think, however, that the anxiety for evacuating the smallest particles has been too great, and that their discharge may be safely trusted to the first flow of urine.

If an artery bleeds, it must be confined by a ligature; but if this is impracticable, a roller should be placed in the wound, preserving a passage for the urine by a canula. The body should then be raised, so that the wound may depend; and in this state the patient must be placed in bed.

The operation sometimes fails by the incision being made too far towards the urethra; for wounds in the urethra cannot facilitate the extraction of the stone; and, in these instances, the bladder is opened imperfectly, and the gorget slips into the cellular membrane. The urethra is indeed divided by the cutting gorget, with the neck of the bladder; but the perfection of the operation consists in making a fair and proper opening into the bladder itself. Sometimes, when the operator has not made a fair, bold incision, too much is trusted to the gorget, and the bladder is lacerated. We know from De Romanis' operation, that lacerations of the bladder are not always fatal, as well as from the lateral method, previous to the introduction of the cutting gorget. But there is much reason to believe that such lacerations are at least dangerous, and probably some of the fatal events may have been from the mortification subsequent to such violence.

Another error is carrying the incision too low, or in the lower part too near the raphe, by which the rectum is wounded, and the fæces afterwards constantly discharged from the wound. The error is not indeed fatal, but the future life is truly miserable. The place at which the proper incision must be made is indeed limited; but it is so nicely defined, that we have heard a professor declare he could perform the operation in the dark; and we once knew a celebrated operator who remarked, that he declined the operation, rather from the bluntness of his touch than of his sight.

After the operation tired nature sinks to rest; but from forty to fifty drops of laudanum are usually given to take off irritation. After a few hours, however, pains, apparently spasmodic, come on in the lower part of the abdomen. These are relieved by anodyne clysters and fomentations. Should the pain increase, and the belly become hard, the case must be treated like enteritis; but anodynes may be more freely given, and warm clysters frequently thrown up. The warm bath is in these circumstances often useful. In many cases, however, notwithstanding every care, mortification comes on, the wound appears foul and livid. In better circumstances it looks healthy; in a day or two

the urine is discharged from the urethra, and a cicatrix is formed in about six weeks or two months. Incontinence of urine, which often follows, is relieved by tonics and cold bathing.

Calculus in females is by no means a common complaint, and the operation is rarely required. When the neck of the bladder and the urethra are opened from the vagina, great inconveniences occur in future labours, from the contraction induced by the cicatrices; but, when the operation is performed, these parts are usually divided by the cutting gorget. We suspect that, in women, what is called the high or De Romanis' method would be most advisable; but as the urethra is so easily dilated, there are few stones that could not be extracted without cutting.

Mr. Bromfield describes the following method of dilating the urethra, apparently better than by means of tents. With the assistance of a straight, blunt, director, he introduced into the bladder the closed end of the appendicula intestini cæci of a small animal; and leaving out, at a proper length, the open end, he filled it with warm water by means of a syringe, and prevented the water's escape by a ligature. He then, by twisting the exposed end of the tube, forced the contained water forwards, and this operation was repeated from time to time, till the neck of the bladder was so much opened, that the forceps might have easily been admitted, if required. The stone, however, was propelled by the urine, and the instrument was not necessary. After the passage of the stone, the parts were fomented with warm milk, and with camphorated spirit of wine. Very little inflammation came on, and no disagreeable symptom. See his Observations and Cases, vol. ii.

Mr. Gooch extracted a stone of four ounces weight, through an incision which he made from the vagina into the bladder. This operation was attended with very little trouble, either to himself or the patient; the ulcer soon healed by the use of soft balsamic injections, and no inconvenience was observed after the healing of the parts. See Cases and Remarks, vol. ii. p. 182, &c.

Stones impacted in the urethra are often discharged by the efforts of nature, and it is frequently astonishing to what a degree the canal may be dilated. Gentle means are therefore first necessary, and oily frictions, gentle pressure, with the semicupium, and large doses of opium, will often succeed. If an operation is required, the skin should be drawn forward, and the urethra divided on the stone. The skin, when restored to its former position, will prevent the urine from flowing through the wound, which will often heal by the first intention. The operation should not, however, be so long delayed as to allow inflammation to come on, for mortification would be the consequence. When the stone is impacted near the neck of the bladder, the operation is the same as cutting on the gripe. When near the orifice of the urethra, the canal may be dilated by elastic forceps. When near the scrotum, it should be either pushed backwards or forwards, and treated according to the plans already described.

See Sharp's Operations of Surgery. Sharp's Critical Enquiry. Heister's Surgery. Bromfield's Cases and Observations, vol. ii. ch. 8. Le Dran's Operations. Heister's Dissertation on the High Apparatus. Bell's Surgery, vol. ii. p. 41, &c.

LI'TRON. NITRON. See ANATRON.

LI'TUS, (from *lino*, to anoint). See LINIMENTUM.

LIVER OIL. See OLEUM JECORIS ASELLI.

LI'VIDUS MUSCULUS, (from *λίθος*, blackish, from its colour). See PECTINEUS.

LIX, (from *λίξ*, light; or from the Hebrew term *lus*). See CLAVELLATI CINERES.

LIXIVIATIO, the separation of salts by solution.

LIXIVIUM, (from *lix*, wood ash). A LEY. That is, water impregnated with the salts of burnt vegetables.

LIXIVIUM TA'RTARI. See KALI AQUA.

LIXIVIUM SAPONA'RIUM. See KALI PURI AQUA.

LOBE'LIA. An American plant named in honour of Lobel, found in woods and dry marshes. With the root of the *lobelia syphilitica* Lin. Sp. Pl. 1320, the American Indians cure the most virulent pox. Five or six of the plants are boiled in water, and the patient drinks as much as he can of this decoction, in the morning and during the day. It soon purges, and the strength of the decoction is increased or lessened as the patient can bear the evacuation. If any part is sore, it is to be washed with this decoction, and thus in two or three weeks a cure is performed. Every part of this plant abounds with a milky juice, and has a rank smell. The root, which is the part preferred in medicine, in taste resembles tobacco, and sometimes excites vomiting. A handful of it, dried, is boiled in twelve pints of distilled water, till they are reduced to eight. The patient begins with half a pint, morning and evening, then more frequently if the purgative effect is not too violent. Should it be so, the medicine must be omitted for three or four days, and then again taken, till the cure is completed. The ulcers are to be washed with a decoction of the root, and if deep and foul, sprinkled with the powder of the inner bark of the *ceanothus Americanus* Lin. Sp. Pl. 284. We owe this description to Sir W. Johnson's influence, who received it from the American Indians. The practitioners of their country, however, do not repose in it much confidence, and seem to think its purgative effect the most striking.

LOBE'LLUS, LO'BULUS, (a dim. of *lobus*, a lobe). A SMALL LOBE. The cells of fat are called *lobuli adiposi*; and the extremities of the bronchiæ, which end in little knobs, are called *lobuli pulmonum*. Winslow calls the lobe of the ear *lobus*, or *lobulus*. See AURICULA.

LO'BUS ECHINA'TUS. See BONDUEH INDORUM.

LOCA'LES, (from *locus*, a place). Diseases that affect, or have their seat, only in a particular part of the body. See MORBI ORGANICI and PLAGÆ.

LOCA' LIS MEMBRA'NA. See PIA MATER.

LO'CHIA, (from *λοχίαια*, to bring forth). The DISCHARGES OF THE UTERUS AFTER CHILD BIRTH, *gynæcia*, the third species of Dr. Cullen's *menorrhagia*, which he defines, a sanguinary menorrhagia in lying-in women. This discharge arises from the distended vessels, and proceeds till the removal of the distention admits of their contraction. In weak, exhausted constitutions, the discharge often continues for several days, and then only becomes a disease. In healthy habits it continues to flow freely for an hour and more, and the discharge afterwards lessens; in a few days it becomes less red, and then greenish. The redness begins to disappear when the breasts fill with

milk. Its quantity is generally less after a miscarriage than when a woman goes her full time; and it sooner stops when a woman gives suck, than when she does not.

The *lochia* may produce disease when deficient or redundant. The discharge in many women is inconsiderable; but, as this appears constitutional, no inconvenience arises. When exposed to cold, or fever comes on, the discharge often suddenly stops, the belly swells and is sore; a heavy load is felt in the lower part of the abdomen and in the loins; the pulse is full and hard; pain in the head and back; a nausea, sometimes a vomiting, and a difficulty of breathing, come on. Feverish symptoms, particularly rigor, generally precede the suppression of the discharge, rather than follow it, and are the cause, instead of the effect; though the effect so soon follows, that it is often difficult to say which has preceded. Violent passions will sometimes check the *lochia*, and sudden grief be equally injurious. Errors in diet, and particularly indulgence in spirituous liquors, seems occasionally to bring on a spasmodic stricture, accompanied often with fever. A diarrhœa, or any other copious discharge, will also check the flow, though with less inconvenience. The nearer the period of the suppression is to that of delivery, the greater is the danger; and the occasional returns of the discharge are symptoms of recovery. The *lochia* sometimes diminish gradually, and sometimes cease at once. A delirium, in many instances, succeeds, occasioning convulsions and death, and if the patient escapes with life, she sometimes continues lunatic.

In general no medicine will force the return; and our chief attention must be directed to procure a relaxation of all the extreme vessels. When the patient is full and plethoric, the pulse full and hard, the face flushed, it has been the practice to bleed copiously, and this has been attended with success, even no fever has come on. It must, however, be done early and boldly, or it will be injurious. As this then is the case, the practitioner should be cautious in what constitutions he makes the attempt.

Emetics are often remedies of importance in this complaint, and should be repeated. To these the relaxing diaphoretics should succeed; and when any organ is overloaded, in consequence of the suppression, a blister applied to the part will be of singular service.

Cathartics are equally necessary, but we should be cautious lest too great a discharge from the bowels prevent a return of the salutary evacuation. It is necessary to relieve too great fulness, and equally proper to avoid irritation; and the infusion of senna with manna, or castor oil, so as to procure two or three motions, will be sufficient. We must then return to the mild relaxing diaphoretics, avoiding great heat, and admitting free air, if not too cold.

In the usual course, the milk is the vicarious discharge of the *lochia*. This evacuation should therefore be encouraged by warmth to the breast, by glasses; but, above all, by applying a strong, healthy child. If a flow of milk can be determined to these organs, the woman is secure. This, however, is often with difficulty obtained; and we more frequently find, that by removing congestions of every kind, supporting the patient with mild, nourishing food, she gradually

covers without a return. We need not add, that the disease is highly dangerous.

The spirits, whatever be the cause, are usually much depressed, and it will be right to cheer our patient in this period of peculiar distress and disappointment, by every favourable representation. In fact, however, the lochia are seldom wholly checked without accession of fever, which, from the time of its attack, is styled puerperal. (See PUERPERALIS FEBRIS.) The idea of checking the discharge by rising too soon, if cold be avoided, is truly ridiculous.

The lochia are sometimes redundant; but this disease must be distinguished from flooding during labour, from an attachment of the placenta to the os uteri, or other causes. The complaint we now speak of is the discharge subsequent to labour; and, in this place, we cannot add to what we have said in the article HÆMORRHAGIÆ, q. v. As the disease is rapid and violent, so our remedies should be proportionally active and continued. Fainting should not be obviated; and the practitioner should be particularly cautious that no irritation is kept up from any accumulations in the rectum. Ligatures on the lower extremities are not only useless, but soon become injurious.

LOCHIORRHŒ'A, (from λοχια, the lochia, and ρεω, to flow). An excess of the lochia after they become pale or whitish.

LOCULAME'NTA, (from *loculus*, a bag). The cells in the fruit of plants where the seeds are lodged, divided by small partitions. See CAPSULA.

LOCU'STA, (quasi *locus ustus*, because from their influence corn is apparently burnt). The GRASSHOPPER; the outer covering of the flower and grain of corn which incloses the chaff; and a name for the LACTUCA AGNINA.

LO'GAS, (from λεγω, to elect). The white of the eye. See ADNATA.

LO'HOC. See LINCTUS.

LO'LIIUM, (from λαιον ολειν, *segetem perdere*,) *aira*, *gramen loliaceum*, *lolium tremulentum* Lin. Sp. Pl. 122; DARNEL, IVRAY, and COCKLE.

It is distinguished from other corn by its slender flat ear, but is not used in medicine. It is said to produce drunkenness if taken inwardly, and to prevent it if applied outwardly. It is certainly a narcotic, and imprudently taken has been highly injurious. See Raii Historia.

LOME'NTUM FA'BÆ, (from λειωω, to levigate). BEAN MEAL, or bread made from it. See FABA MAJOR.

LONCHI'TES, (from λογχη, a lance, because its leaves are sharp pointed). *Filix aculeata*, *polypodium lonchitis* Lin. Sp. Pl. 1548. The root is aperient and diuretic, but not used in the present practice.

LONCHO'TON. See VITRIOLUM.

LO'NGANON, (from longus, long). See RECTUM INTESTINUM.

LONGI'SSIMUS DI'GITUS. See DIGITUS.

LONGI'SSIMUS DORSI, is a muscle named from its length, and has the same origin with the sacro-lumbaris. It is inserted by several digitations into the ribs on the inside of the upper part of this muscle; between it and the complexus the transversalis colli of Albinus is seated, which runs from the transverse processes of

the vertebræ of the back to those of the neck, and raises the body.

LONGI'SSIMUS O'CULI. See OBLIQUUS MAJOR Oculi.

LONGI'SSIMUS POL'LICIS MA'NUS. See FLEXOR TERTII INTERNODII POLLICIS.

LO'NGUS COLLI, (from λογχη, a lance). Rises from the two upper vertebræ of the back, and is inserted into the three upper vertebræ of the neck. It is made up of two plates, which decussate each other; and receives slips from some of the lower transverse processes of the neck. Its office is to bend the neck.

LONI'CERA PERICLYME'NUM. See CAPRI-FOLIUM.

LOOK, a gum resin, whose source is unknown. It is a stimulant, and supposed to be a resc'vent.

LOPE'ZIANA RADIX, a root brought from Goa, and first described by Gaubius in his Adversaria. It is brought to us in pieces, about two inches thick; of which the woody part is lightish and white, the medullary part more dense and reddish. The bark is rough, wrinkled, brown, soft, and apparently woolly, covered with a paler cuticle. Neither had any striking smell or taste; but it was found highly useful in colliquative diarrhœas, especially in the last stages of phthisis, appearing to act rather as a narcotic than an astringent. Gaubius thinks that it resembles the simarouba.

LOPHA'DIA, LO'PHIA, (from λοφος, the hinder part of the neck). See SPINA. Lophia sometimes signifies the upper part of the back of the neck.

LO'PIMA, (λοπιζω, to decorticate). See CASTANA.

LO'RA. See DEUTERIA.

LORDO'SIS, (from λорδω, bowed or bent inward,) is an incurvation of the spine toward the fore parts; and the opposite to gibbosity. It is synonymous with lumbago, tabes dorsalis, and with a curvature of the legs inward.

LORICA, (from lorica, a coat of mail). A lute with which glass retorts, &c. are coated, before they are put into the fire.

LO'RIND MATRI'CIS. An epilepsy, or a convulsive disorder supposed to proceed from the uterus.

LO'TIO, (from lavo, to wash). A LOTION; an external fluid application. When used on the eyes, it receives the name of *collyrium*; on the face, a *lotion*; on any other part an *embrocation*. It is the appellation of clyster, and a name of the urine.

LO'TIO ALU'MINIS. See INFLAMMATIO.

LO'TIO AMMO'NIÆ MURIATÆ, LO'TIO AMMO'NIÆ ACETATÆ. See INFLAMMATIO MAMMÆ.

LO'TIO AMMO'NIÆ MURIA'TÆ CUM ACE'TO. See INFLAMMATIO.

LO'TIO SPIRITUO'SA. See AMBUSTA.

LO'TUS, (from λω, to desire, from the deliciousness of its fruit). The species used in medicine are noticed under the different names they bear.

LO'TUS A'RBOR, *Celtis Australis* Lin. Sp. Pl. 1478, the LOTE or NETTLE TREE, grows in the southern parts of Europe; its berries are astringent.

LO'TUS URRANA, *trifolium odoratum*, *melilotus major odorato violacea*, *trifolium m. officinale* Lin. Sp. Pl. 1078. SWEET TREFOIL. The seeds, leaves, and flowers, are supposed to be anodyne and diaphoretic.

LOXA'RTHRUS, (from *λοξος*, *oblique*, and *αρθρον*, *a joint*). An obliquity of the head of bones, and the muscles annexed; of the joint to a degree of deformity, without luxation or spasm.

LUCE (EAU DE). See ALCALI.

LU'CIDUM SAL, (from *luceo*, *to shine*). See GEMMÆ SAL.

LU'CIDUS LA'PIS, (from the same). See BONO-
NIENSIS LAPIS.

LUCI'NA, (from *luceo*, *to shine*). DIANA. See ALILAT.

LU'DUS HELMO'NTII, (from its resemblance to a die). A roundish mass, which seems to have cracked in drying, and the interstices to be filled up by a calcareous matter, which frequently rises above the surface. The whole is an argillaceous clay, and the mass consists of prisms of different sizes separated by the calcareous matter. See Haüy, iv. 455.

Paracelsus described the cubic pyritæ, which are like dice, and called them *ludi*: Helmont mistook him, and supposed this stone, which is mostly divided into squares, by the cracks to be the substance. The spar that fills up the cracks is only to be used; for it is that alone which promotes urine, and is supposed a remedy for the stone.

LU'ES, (from *luo*, *to dissolve*, because it produces dissolution; or from the Hebrew term, *laugh*, *to absorb*,) the PESTILENCE in men, and the MURRAIN in beasts.

LU'ES DEI'FICA. One of the ridiculous names for the epilepsy.

LU'ES NEURO'DES CONVULSI'VA, a mild typhus.

LU'ES VENE'REA. THE VENEREAL DISEASE. *Aphrodisiacus* and *Gallicus morbus*, *grand gor*, *Patursa morbus Indicus* and *Neapolitanus*. Dr. Cullen names it *syphilis*, and places it in the class *cachexiæ*, and order *impetiginæ*, defining it a contagious disease, arising after impure coition, and a disease of the genitals; ulcers of the throat; corymbose papulæ of the skin, particularly at the margin of the hairy scalp, running in scabs and scabby ulcers; pain in the bones, and exostoses: one species only exists.

The source of this disease has occasioned much controversy, which, though not interesting in the result, is not without curiosity, and a slight attention to it is, on this occasion, necessary. It has been generally supposed that the venereal disease is a native of America, and was brought to Europe by Colon (Columbus); an opinion supported by the apparently minute accuracy of Dr. Astruc, whose evidence has not been carefully appreciated, neither has the whole been properly adduced. Columbus returned from his first voyage in 1494, and from his second in 1496; but there is not the slightest pretence that the disease was brought to Europe on his first return. His seamen are said to have been in good health; and in his life, collected from his own MSS., by his son Ferdinand, not a word occurs of any disease of this kind. Columbus too returned in March, 1494: at this time the disease began to rage in Naples. He landed in Portugal; but in this country the disease did not appear till two or three years afterwards. The medical authors who wrote in 1496 mention it as a new disease "*then raging*," and some of these date it two years before. Hock de Brakenaw, a professor of medicine at Bologna, fixes its era in

1494; and he wrote only eight years afterwards. Cautaneus, who wrote in 1505 at Genoa; and De Vigo, physician to the pope, whose work was published in 1512, both professional men, living almost on the spot, and so very near to its first appearance, fixed its earliest era in 1494. Pintor, a Spanish physician, who resided at Rome as physician to Pope Alexander VI. from 1492 to 1502, and who wrote in 1499, fixes its era also at 1494. Fulgosius, and some other authors, assign an earlier period to its appearance; but there is much doubt whether it was known before the end of 1493. Coccius, in a work published at Venice in 1502, dates its era in 1495; and Jean de Bourdigne, the French historian, remarks, that it began to rage in France in 1495. The evidence of Columbus importing it, on his return from his second voyage, is more striking, but equally inconclusive. He returned in 1496, and Oviedo describes Moses Peter Margarita as affected "with the distemper." He observes, that he had so many pains that he *believes* he had also the pains of that disease. The two hundred and twenty-five soldiers who returned with him were undoubtedly in a wretched state of health; but previous to their embarkation they had been besieged in their camp by the Indians, and reduced to live on the most unwholesome food. In this state they crossed the Atlantic. They are described not as having bubos, or cutaneous eruptions, but as of the colour of saffron.

It is singular, that if the venereal disease was of American origin it should not be traced by cotemporary authors to America. The new world was never accused of sending us this scourge till after the third voyage of Columbus, and then, indeed, it was received from thence, though undoubtedly first carried there; nor has any author shown that it was endemic in America. They indeed describe a cutaneous disease, which still exists, and is styled at present the *yaws*, of which the pain is apparently a modification.

The origin of lues, though seemingly connected with the discovery of America, is more strictly so with the expulsion of the Moors, who, driven from Spain, retired to Italy, and resided on the outside of the Appian gate at Rome, when some of them clandestinely entered the city. The cutaneous diseases of that race engrafted on constitutions enfeebled by the plague, or united with the prevailing epidemic, apparently produced a new and distinct disorder. We shall suin up the whole in the words of a critic in a periodical journal, who has seemingly examined the subject with considerable attention in the original authors.

"The summary of the whole may be very short. In Italy, from the year 1491 to 1495, from the great inundations and severe droughts succeeding each other, pestilential fevers of the most fatal kind prevailed. The disease was styled the plague; but it appears to have been only a fever attended with the most violently putrid symptoms, among which were glandular abscesses, sores, and blotches, which discharged a malignant sanies. Those who recovered did not soon return to perfect health: the abscesses remained in a chronic form, and the whole mass of blood was infected. In this state the disease seems to have been communicated by infection, at first from the most general contact; and it was continued in this highly infectious state many years,

when it was attended with fever, often of the putrid kind. In better situations it sooner assumed a chronic appearance, and by degrees fixed itself in those parts, so as to be communicated only by personal connection. It is particularly observable, on a minute examination of the authors, that venereal symptoms mixed themselves with those of fever: or, in other words, the peculiar symptoms of that epidemic were such as have since discriminated syphilis. These symptoms continued subsequent to that fever, and were at last communicated by infection to those who never had the fever." See Astruc, Swediaur, and J. Foot, on the Venereal Disease; Becket, Philosophical Transactions, vol. 30 and 31; Sanchez' Historical Investigation into the first appearance of the Venereal Disease in Europe; Hensler's two Treatises on the American Origin of the Venereal Disease; Girtanner's Treatise, in 3 vols. 8vo. at Göttingen; Gruner's supplementary volume to the Aphrodisiacus of Luisinus, published at Jena; Perenottis' General and Descriptive History of the Origin, &c. of the Venereal Infection, 8vo. Turin; Critical Review, vol. 65; Second Series, vol. 5 and 10.

The lues is at present received from infection only, and it usually shows its source by the tumour of the glands, interposed between it and the receptaculum chyli, as in the lymphatic glands of the groin, when received in venereal embraces; in the axilla when by wounds in the fingers, either in dissection or obstetrical labours; and in the neck when received by children suckling, or, as was formerly the case, by kissing. Where the skin is thin, as in the first and last instances, it is absorbed from the surface, but not from the fingers, unless there is a wound. Swellings of the lymphatic glands are not always the consequence of infection. Sometimes no stoppage occurs, and sometimes, as in the glands of the mesentery, either from anastomosis, or a lymphatic escaping a gland (see LACTEA VASA), no inflammation takes place. When children receive the infection from their mothers they are sometimes born with eruptions, chiefly discovered about the nates; but sometimes the disease is not discovered till after about three weeks or a month, when foul ulcers, blotches, or brown copper coloured eruptions, appear about the mouth, the nates, or other parts. It is contended by some pathologists, that, as there appears to be no infection of the blood, it is not probable that the fœtus should be diseased in the uterus. They consider, therefore, the infant as infected at the period of its passing through the vagina. If it were certain the venereal ulcers were never observed at the birth, we might admit this idea; but we think we have in more than one instance discovered them when the child was first washed; and though we admit the general mass to be without any discoverable taint, we know not but that some separation may take place in the maternal part of the placenta. It is sufficient at this time to admit that the child is often infected from the parent; and when the lues has continued, in either parent, for a long period, though then apparently free, the child will soon sink with numerous anomalous symptoms resembling, though distantly only, the lues.

As a running and discharge distinguish a gonorrhœa, so does a small, hard, irritable pimple usher in the more decided lues. This pimple, called a CHANCRE, q. v., is very general, we believe universal, but so little

painful, that it often passes unobserved. In this state it seems to convey no infection, and for a time no matter is certainly absorbed from it; but, at an indefinite period, the glands in the groin begin to swell, and a hard, painful cord, an inflamed lymphatic, may sometimes be traced along the back of the penis to the tumid gland (see BUBO). As the chancre occasionally passes unnoticed, so a bubo, as we have said, does not always occur, and the patient continues in a delusive security, unsuspecting of any disease: yet, if either is attended to, the disease might probably be checked in its bud. We would not, however, enforce such an idea; and we have rather recommended discussing bubos, for this reason, that we avoid a troublesome sore, and at last cannot escape from a mercurial course. It is not, however, by suppuration that the future lues can be averted, but by an extirpation of the gland; yet even this, for the reasons already assigned, would not offer a perfect security.

When neither chancre nor bubo calls the attention to the disease, little inconvenience is felt for some weeks, sometimes many months. It has been contended that the infection may be dormant for many years; but this is certainly not true, and the idea has been cherished to excuse fresh infection. So frequently do patients deceive us in this respect, that it is not easy to fix the limits of the poison lurking unobserved. Perhaps from three weeks to six months some symptoms are usually to be discovered. If minutely examined, the first appearances are a sallow countenance, languor, and listlessness; copper coloured spots on the breast, the arms, and the face, particularly on the forehead, and round the roots of the hair. These by degrees become scaly, occasionally discharging a thin fluid, which forms a scab. Soon afterwards an uneasiness is felt in swallowing, and a livid, flabby inflammation is observed in the throat, with deep ulcers, covered at the bottom with a slough, whose edges are ragged. There is no very marked difference between these and the ulcers of the angina gangrenosa; but they are distinguished by the absence of fever, and their continuance with little, sometimes scarcely any, loss of strength.

These ulcers occasion a hoarseness, and, if near the Eustachian tube, a deafness; and by degrees cover the fauces, or at least extend far over them. If still farther neglected, pains are felt in the bones, chiefly in the harder long bones, as the shin and arms, often in the skull, particularly over the eyes, and at the bottom of the orbits. A swelling comes on the shin bones, and sometimes on the os frontis, which, if neglected, corrodes into a foul ulcer, with a caries, penetrating to the brain. The ulcers on the shin and humerus assume the same appearance; the palate bone equally suffers, and the meat in deglutition is returned through the nostrils. The bones of the nose soon share a similar fate, and the nose sinks flat on the face. When the pains of the bones commence, the strength begins to fail, and, long before these extremities, is so much reduced that the patient crawls with difficulty. Hectic fever comes on, and death closes the loathsome scene.

In the earlier histories of this complaint the symptoms are more various and more dreadful; but on these we need not enlarge, as we have continued the description far beyond the point at which the disease is usually suffered to arrive. In the whole of this course the

blood is apparently untainted. It will not at least communicate the infection; for the matter is largely diluted, and probably sheathed by the albumen. When deposited in the glands, without this medium, its virulence is discovered. By what power it is deposited is among the arcana of physiology, which we can only approach by conjecture (see SECRETION). The poison itself seems to possess an assimilatory property; and, when in a considerable degree of concentration, to be highly deleterious, affecting, by its sedative powers, the nervous system; and even the mind; for a despondency, which the removal of the symptoms cannot relieve, is among its effects when far advanced.

These general appearances are often accompanied by still more distressing local ones. Though we have only mentioned the chancre as the first symptom, it is sometimes followed by painful ulcers, spreading, unobserved, under the prepuce, and gradually destroying the glans, sometimes the whole penis. A suppurated bubo is often equally destructive, forming numerous extensive sinuses which assume the appearance of cancer. Abscesses form in the perinæum, producing fistulous ulcers in the bladder, through which the urine issues, and tubercles, styled *condylomata*, round the anus, almost close the sphincter, or suppurate in fetid, ill conditioned ulcers.

If such and so distressing were the forms of the disease, and they were much more so at its first appearance, we cannot be surprised at the terror which seized the earliest practitioners, who witnessed its devastations without the power of being able to check them. Mercury, its only remedy, was, however, soon discovered, and applied, apparently, at first with a happy boldness by empirics; for *quacksalber*, the German appellation of this metal, was the root of the opprobrious appellation, a quack; though quackery now in a more extensive sense may be found among those who claim a regular education, as well as those whose medical merit lies in the diploma they have purchased.

Mercury is supposed to be a specific in this disease, in other words to oppose its course by properties peculiarly its own. If we bring this idea to a more rigorous test, it will, we think, amount to this; that mercury, by a chemical combination with the virus, destroys its efficacy. This is a subject which, when treating of mercury (see ARGENTUM VIVUM), we reserved, and it is one which has occasioned much controversy. As usual, we must state the outline in a summary way. If mercury acts as a specific, its effects would probably be in proportion to its quantity; but in reality they are in proportion to its active state, or rather to its oxygenation. If, too, it acts in this way, its effects should be the same whether it produced any sensible evacuation or not, for if the poison was destroyed we should be indifferent about its discharge; but this is not the case, for it never cures without inducing some evacuation. The difficulties which stand in the way of its acting as an evacuant only are considerable. The poison is said to possess an assimilatory power, so that whatever portion is discharged, should any remain, the disease must recur. To this we can only reply that, probably, mercury promotes the evacuation more rapidly than the assimilatory power produces new supplies; and as the poison, when formed, is conveyed to the skin, from whence it is most readily eliminated by the mercury, we can easily perceive that in no long period the cause must

be removed. Yet were this the only effect other evacuants should be equally serviceable; and indeed it will be alleged, that those which are determined to the skin, and possess a power of stimulating the extreme vessels, are powerful antisyphilitics. Of this kind it is said are the mezereon, the sarsa, the guaiacum, and probably the volatile alkali; those which operate by the intestines, as the lobelia, and some others, are supposed to be equally useful: but let their respective powers be urged so far as facts will warrant, or as the prejudices of their admirers will carry them, each will be found greatly inferior to mercury, except in a warm climate, where the disease is slight and manageable, often yielding to the power of nature alone. Again: were mercury a specific, its power would be peculiarly striking in the local complaints. It has been said, that the matter of a chancre mixed with a mercurial preparation will not convey the disease; but the experiment has not been so carefully made, or so attentively repeated, as to induce us to rest on it with confidence. But will any one contend, that in venereal sores mercury is not an application more certainly and speedily useful than any other? The smarting of an irritable chancre is greatly mitigated by the dry calomel in powder; the discharge of a bubo meliorated by mercurial ointment. It will be alleged that any warm stimulating application will be equally beneficial. In gonorrhœa, indeed, it will be so; but gonorrhœa and syphilis are certainly distinct in their causes, their progress, and effects. While, therefore, it is highly probable that mercury acts as a stimulant and a tonic, supporting more actively and steadily the action of the cutaneous vessels than any other medicine, we cannot deny that it has some chemical effect on the poison itself, either diminishing its virulence, or disposing it more readily for evacuation.

This peculiar quality is still in obscurity, but we may be allowed to suggest whether it is not at least connected with the oxygen of its preparations. We have occasionally indulged ourselves in conjectures, but have not suffered them to detain us long. We shall now, therefore, shortly remark, that mercurial preparations are, as already observed, active in proportion to the oxygen which they contain; that other substances containing a proportion of oxygen are useful in at least arresting the progress of the poison; that the sallow complexion, the inert, inirritable state of the sores, as well as the appearance of the matter discharged, show that there is a great deficiency of oxygen in the system. If then the mineral acids are only partially effectual in removing syphilis, may we not contend that, besides the oxygen, the steady diaphoretic effect of the mercury is required? When the sarsa and mezereon fail, may it not be alleged that the oxygen is wanting? They do not, indeed, fail in warm climates, where, though the disease is milder, the oxygen is apparently more copiously separated in the ordinary functions.

To the numerous and crowded list of remedies for this disease, M. Acharius of Stockholm has lately added tar-water. Alone, it is said to cure, or to be a powerful auxiliary to mercury or the nitric acid. We need not attempt to connect this opinion with our former observations, till experience has more fully appreciated the value of the proposal.

In whatever way mercury acts, it is admitted to be the only remedy which we can depend on in this

climate. Various are the opinions respecting the preparation to be chosen, the forms of administration, and the conduct of the plan. Every practitioner has his predilections and his prejudices respecting particular preparations; but we are coming back to the earliest views, and it is now generally agreed that the mercurial pill, and the friction with mercurial ointment, are most commonly successful. Of the other internal mercurials, perhaps calomel is equally useful with any other; and though we have, for a long time, employed mercurius calcinatus, we know not that it is superior in efficacy; but to this part of the subject we must return.

In the earlier periods, mercury was employed so freely, or rather so rashly, that the most fatal consequences often ensued. The loss of the teeth and the injury of the sight were among the slightest of these; and sometimes a fatal apoplexy has supervened, which yet occasionally happens, though the event is peculiarly rare. Terrified by these events, practitioners began to think that mercury in very large doses was unnecessary; and the quacks at last contended that their boasted nostrums contained none. In their preparations, indeed, the most active mercurials are employed, and they depend on the colour and the density of their medicine to elude the detection of the mineral; but modern chemistry has too many resources to be so easily baffled, as our remarks in the article ARGENTUM VIVUM will evince; to which we could add some experiments of our own. Others, melioris notæ, assert, that they can cure the disease without salivation; and practitioners of credit do not often *require* confinement. Yet, in such cases, relapses we have found not uncommon; and though confinement may be sometimes dispensed with in warm weather, it will be more safe to enjoin it. The severity of the old process is greatly mitigated since the days of Pott, and the last author of that school who countenances it is, we believe, Mr. Howard. Yet when the disease has long continued, where the bones are greatly affected, and every part of the system seems to be contaminated, this severity should still be employed. Without it, in such cases, there is no safety. In more recent complaints, a milder course may be trusted; and a spitting, not exceeding a pint in a day, continued for about three weeks, or a month, will often effectually cure. It must, however, be remembered, that the longer the disease has continued, the more intimately it appears to have penetrated, the more active must be the salivation, and the longer should be its duration. In general, gargles, and any applications, except the mildest, should be avoided; for though the topical complaints will be sooner relieved, these should be left as indices to enable us to judge of the state of the constitution. In cases where discovery is dreaded from these local affections, this precaution may be disregarded.

It has been a question, whether, when other discharges are increased, salivation is necessary. When the cutaneous evacuation, or the urine, is evidently and copiously increased in quantity, it is highly probable that the disease will be equally removed. Yet no prudent practitioner will wholly depend on these discharges. We know only that mercury is accumulated in the system by its affecting the mouth; and un-

less accumulated, the disease will not be cured. Yet many persons no quantity of mercury will salivate, and to increase the dose beyond due bounds may be dangerous, as a most profuse and violent spitting sometimes attacks at once. In such instances, we have found it advantageous to employ the assistant medicines, as the mezereon, &c.; and to watch the progress of the local complaints. When these have yielded, and the constitution in general is amended, the omission of mercury may for a time be allowed, and it may at a future period be commenced with more success. When we have perceived from these indices that little has been gained, rubbing calomel on the gums, a practice recommended, we believe, first by Mr. Cline, has succeeded, though troublesome ulcers in the mouth have sometimes followed.

When mercury has conquered the general disease, the local ones often continue troublesome. The sores in the throat are, indeed, frequently the effect of the remedy, and may be distinguished from true venereal sores by their being less deep and foul, with edges less ragged, or insensibly lost in the epheleon. These may be healed by discontinuing the medicine, and using gently astringent gargles. The nocturnal pains, the gummata, *tophi et nodi*, and the venereal excrescences, often continue after the constitution is wholly cleared. The mezereon will relieve in many instances the pains; and the warts must be treated, like any others, with caustics, or the knife. The gummata we have already described, and need only add in this place, that if the mezereon, with the topical application of mercurial ointment, does not succeed in reducing them, they will at least be no longer painful; but, should the patient still wish to be effectually cured, the surgeon may make an incision on the bone, and cut out the tumefied part, bringing on a suppuration to complete the cure. The process is, however, painful and troublesome; nor is it advisable on the head, since the node often arises in the diploe of the skull, and each lamella is equally affected.

The doses of mercury must be managed with caution, and very slight ones first employed. If we give the mercury oxygenated by triture, about four grains of the blue pill of the Edinburgh Pharmacopœia, which contains a grain of mercury, will be sufficient, if repeated three times a day. If calomel or mercurius calcinatus is employed, a grain night and morning at first, or two grains at night, guarded with a grain of opium, lest it should irritate the bowels, will be a proper dose. If the ointment is preferred, half a drachm of the strong mercurial ointment may be rubbed in night and morning. In about a week or ten days, by either plan, the mouth will be slightly sore, and the repetition may be regulated by its degree, or by the violence or duration of the complaint. In many cases the bowels will be so much affected by the mercurial, that no doses of opium will check the pain or diarrhœa: in many the salivation comes on so rapidly that the effects on the disease cannot be depended on. Sometimes opium, sometimes the hæmatoxylon, the catechu, the kino, the oak bark, or tormentil, will check the discharge on the bowels; and the Dover's powder, pulvis ipecacuanhæ compositus, with a warm regimen, and a flannel shirt, prevent its affecting too soon the mouth.

In each instance, we must proceed very cautiously with the medicine, to accustom the constitution to its irritation.

The other preparations chiefly in use are Plenck's powder, the solution of the sublimate, the mercurius acetatus, and alkalisatus. From these we seem to derive no peculiar advantage, nor are the two latter, as is pretended, less irritating to the bowels. Plenck's gummy solution of mercury sometimes appears to be so, but is not on the whole superior. The solution of the muriated mercury, introduced by the baron Van Swieten, was for a long time trusted. It affected the bowels only in a slight degree; and when its menstruum was corn spirit, it sat easily on the stomach. It soon appeared to check the disorder, but here unfortunately its merits rested. When the complaints were diminished, the medicine would affect no more, even though the dose was increased; and in some instances, even during its use, the worst symptoms appeared to return. Fumigations, which were formerly much employed, are now seldom trusted, and seem chiefly useful by bringing on, more rapidly, mercurial effects on the salivary glands.

In a very low state of the constitution, when hectic symptoms prevail, mercury is of doubtful efficacy; but cautiously and gradually administered, it does not increase hectic symptoms; and it is not difficult, even during the progress of phthisis, to arrest, in a great measure, venereal symptoms. Though its action on the salivary glands is necessary to show that it is introduced in sufficient quantities, yet when these are soon affected, as we have said happens in some constitutions from idiosyncrasy, and very generally in scorbutic habits, there is no opportunity for its power being communicated very generally to the smaller vessels. In such cases it must be resigned, if a warm regimen and the relaxant diaphoretics, just mentioned, will not direct it to other excretories.

In these and similar cases we must apply to what may be called the accessory specifics, and we fortunately have some active medicines of this class. Among these we may reckon the MINERAL ACIDS, particularly the nitrous. The nitrous acid was warmly recommended to us from the experience of the Indian practitioners. Our expectations, often deceived by pompous promises, were not raised high when we were informed that its effects were equal to those of mercury; but, though far inferior, it is a medicine highly useful. The nitrous acid will not cure lues, but it will arrest the symptoms and restore the strength in those intervals when mercury can be no longer borne. It will sometimes in these intervals seem even to advance the cure, and we can truly add, that the methodus medendi has not for many years received a more powerful auxiliary.

The other accessory antisyphilitics are the bark, opium, china root, guaiacum, sassafras, astragalus, lobelia, lupulus, dulcamara, sarsa, and mezereon. We have arranged them in what seems the order of their efficacy, commencing with the least powerful; omitting the volatile alkali, muriated barytes, the juniper, the cicuta, the green rind of the walnut, the bardana, and saponaria, as of very inconsiderable, if any, power. On the individuals of the former class we shall add a few remarks.

The peruvian bark has, alone, no power of checking the progress of the syphilitic infection. Yet it is often

highly useful in lues, when mercurial ulcers occur in the mouth; when the ulcers of suppurating bubos assume a livid appearance, or those in the perinæum are foul, with deep sloughs. It has been contended that it meliorates venereal symptoms; but, in reality, it only lessens their painful irritation by diminishing irritability. The cicuta, and the green rind of the walnut, in the second class, act in the same manner, if indeed they have any effect.

Opium has been celebrated as a certain antisyphilitic, and, in many instances, it has had apparently a powerful effect. This, however, is temporary only, and the symptoms have returned with increased violence. It acts like the former medicine by lessening irritability, and in some measure perhaps as a diaphoretic. In this way it is peculiarly useful in mercurial ulcers. The china root, the guaiacum, sassafras, astragalus, escafus, lobelia syphilitica, lupulus, and dulcamara, are not found to answer the high expectations formerly entertained of them. The three first are occasionally ingredients in diet drinks, and the three last are, in this country, scarcely ever prescribed.

The sarsaparilla has retained a considerable credit, and is even now generally employed. What its effects may be in a recent state we know not, but we have found its powers inconsiderable in this country, though we have given large doses in substance. It appears to be chiefly mucilaginous, with few sensible properties, which would lead us to suppose it active.

The mezereon, on the contrary, is a powerfully stimulating diaphoretic, from a plant strongly narcotic, and seems to combine the united virtues of the rest. It has alone often effected all that has been expected from the others, which in many instances seem to overwhelm instead of adding to its powers.

If we examine these antisyphilitics we shall find them in general narcotic; in a few instances merely mucilaginous, and in general diaphoretic. If the sarsa is not merely mucilaginous, it is diaphoretic. From each property we perceive that some advantages may be derived in lues; and when all are combined, the effects may be more salutary. In the mezereon we combine the diaphoretic and the narcotic; in the sarsa, the former with the demulcent; in juniper, the bardana, the sassafras, and the guaiacum, we have probably only the diaphoretic, or with a less degree of the mucilaginous; in the dulcamara, lupulus, astragalus, the green rind of walnut, bark, and opium, the narcotic only. The same views assist us in forming a judgment of their comparative merit; but their order was long since fixed by experience, before we had occasion to examine the source of their efficacy. Above all we must reflect, that those which have any claim to a diaphoretic power are given in decoction, by which the active particles are attenuated and conveyed to the skin; and these only are useful where the disease has penetrated to the minutest vessels.

Mr. Bell observes, in his Treatise on Ulcers, that those which are the result of a venereal taint of a long continuance, are singular in the appearance of their discharge. It is at first thin, but soon becomes tough and viscid; having a very loathsome, though not the ordinary, putrid smell, and a singular greenish yellow colour. In such ulcers as have a lues of long continuance

for their cause, we should depend on the effect of mercury given internally, contenting ourselves with such external applications as will keep the sore clean. In this manner the different ulcers are, as we have said, indices that the disease is eradicated from the habit. Venereal ulcers are apt to inflame, and are then painful; but a saturnine poultice will relieve the inconvenience, and the unguentum cereum Pharmac. Edinb. will be only required. If the ulcer is seated near a bone, the appearance of fungous flesh will lead to a suspicion of caries; and besides the proper treatment for carious bones, mercury must be administered. These ulcers are often obstinate, though every venereal symptom is removed; and this is frequently owing to some other disease, which will require attention. The sores, however, will sometimes not heal from the effects of mercury, and then the bark, opium, or both, with a nourishing diet, a pure air, and moderate exercise, will usually succeed. If the sloughs on these ulcers are tough, dressings that gently stimulate will be required; and two drachms of the nitrated quicksilver may be added to an ounce of the unguentum resinæ flavæ for this purpose. When a gland is the seat of an ulcer, a salutary suppuration is with difficulty produced, and the gland, at least the hardened part of it, must be destroyed by repeated applications of the argentum nitratum. See Bell on Ulcers, vol. vi. p. 381, &c.

An eruption of the skin is sometimes also the consequence of a free use of mercury, attended with a fever, usually idiopathic. The skin is affected with a prickling sensation, and a rash follows, which terminates in branny scales. The skin, however, is left in a state peculiarly tender and irritable, which is relieved by bark or opium, but, above all, by the mineral acids.

When venereal ulcers appear cancerous, fresh air, a fuller diet, abstinence from mercury, and hemlock applied outwardly, or given inwardly, will sometimes succeed. A more speedy effect has been observed from eating several lemons in a day. See some observations of this kind in the London Medical Transactions, vol. ii. p. 338, &c. Venereal ulcers in the throat may be conveniently relieved with the following: R. Hydrargyri muriati, gr. x. acidi muriatici, gut. v. tinct. lav. c. ʒi. m. cap. gut. v.—xx. bis. die, in aq. pura vel jusculi avenacei.

Astruc on the Venereal Disease, or Chapman's Abridgment of Astruc; Heister's Surgery; Fordyce's Elements, part the second; Falck's Treatise on the Venereal Disease; Fordyce's Review of the Venereal Disease; White's Surgery, vol. iv. p. 399, 423; Swediaur, Plenck, Howard, Bell, and Hunter, on Venereal Complaints; Pearson's Observations on the Effects of various Articles of the Materia Medica in Venereal Complaints.

LU'JULA, (corrupted from the diminutive ALLELUJULA, q. v.). ACETOSA.

LUMBA'GO, (from *lumbus*, a loin). Pain in the loins. See RHEUMATISMUS and ARTHRITIS.

LUMBA'GO PSOA'DICA, and APOSTEMATOSA. See ARTHROPOISIS.

LUMBA'LIS MU'SCULUS, (from the same). See PSOAS.

LUMBA'RES NE'RVII, (from the same). The LUMBAR NERVES pass out from the spinal marrow through the vertebræ of the loins, and become larger

from the first to the last. The first lumbar nerve throws a large branch backward, and two filaments to the intercostal: the trunk of the nerve goes through the psoas muscle, then to the spine of the os ilium, at whose anterior superior process it throws off several branches to the muscles, and one to the spermatic cord in the male, and to the round ligament of the female. The first going to join the second, sends off two filaments; one of which goes to the spermatic cord, the other passes under the Poupart's ligament to the groin; from this the pain felt in the thigh during a fit of the stone is explained.

The second lumbar nerve lies on the inside of the psoas muscle, goes through its head, and runs along it; then passes through the annular aperture of the obliquus externus to the scrotum in males, and the labia in women. The second lumbar nerve joins with the third; and that again communicating with the fourth, forms the crural nerve. See CRURALIS.

The fourth and fifth lumbar nerves, and the three first sacral, form the sciatic nerve, which, passing out at the great sciatic notch, runs down between the tuberculum ischii and trochanter major, along the internal and posterior part of the thigh, between the biceps and seminovosus, as far as the ham, rather nearer the inner condyle of the os femoris than the outer. See CAUDA EQUINA.

LUMBA'RES ARTE'RIÆ go out posteriorly from the inferior descending aorta, in five or six pair, in the same manner as the intercostals. The upper ones send branches to the neighbouring parts of the diaphragm and intercostal muscles, and supply the place of semi-intercostal arteries; they are also distributed to the psoas, and other adjacent muscles; and, by perforating the oblique muscle, they become external hypogastric arteries. They also go to the vertebral muscles, and enter the spinal canal.

LUMBA'RES VE'NÆ proceed from the vena cava, near the bifurcation, and principally on the right side; sometimes from the left iliac vein; this branch communicates with the azygos and intercostal veins.

LUMBA'RIS EXTE'RNUS. See QUADRATUS LUMBORUM.

LUMBA'RIS INTE'RNUS. See PSOAS.

LUMBA'RIS REGIO. THE REGION OF THE LOINS is the posterior external region of the belly, extending from the lowest ribs on each side, and the last vertebra of the back, to the os sacrum, and the neighbouring parts of the os ilium. The sides of this region are strictly called the loins, and include also the musculus quadratus lumborum on each side of the lower portions of the sacro-lumbares, of the longissimi, and latissimi dorsi, the musculus sacer, &c.

LUMBRICALS MU'SCULI, (from their resemblance to a worm,) *vermiculares, fidicinales, flexores primi internodii digitorum*, the productions of the flexors of the fingers and the toes: originating from their respective tendons, after encircling the basis of each finger and toe they join with the extensors. Their office is, when the extensors have done their utmost, to finish the extension, and, when the flexors have done their utmost, to finish the flexion.

LU'MBRICI, (*à lubricitate*, from their slipperiness). The lumbricus, which abounds in the intestines of young persons, resembles so nearly, in its general

appearance, the earth worm, that it has been considered as the same animal. It is, however, distinct, and is the *Ελμινς στογγυλα* of the ancient physicians, distinguished from the earth worm by wanting the elevated ring in the middle of its body. The body of the *ascaris lumbricoides*, for this is its generic name, is round; its head furnished with three vesicles, placed in a triangular form; generally from twelve to fifteen inches in length, and about the diameter of a goose quill. The head may be distinguished by the three vesicles mentioned, and the triangular space between is the mouth of the animal. The tail terminates suddenly in a very sharp point, and near it the orifice of the anus may be distinctly seen. Near the middle of the body is a circular depression about three lines in extent, in which is an aperture like a small point. This band is most conspicuous when the body of the worm is distended, and it seems wanting when the body is collapsed. Just below the mouth are two small transverse clefts, which Bruguiere calls *stigmata*, and thinks them the organs of respiration.

Two longitudinal lines extend through the whole body of the worm; which are the tendons to which the semicircular muscles are attached. The animal, however, does not move, like the earth worm, by a vermiform motion, but curls its body in circles, from which it extends the head. A number of vesicles surround the intestinal tube, which proceeds, without any change of direction, from the head to the anus, but they do not extend beyond the depressed band. Below it the connecting medium appears to be a common cellular substance. These vesicles are filled with a mucous, probably a nutritious, fluid. The intestinal canal contains a dark green fluid, resembling the meconium of infants. But even from the lower part of the canal filaments appear to arise, which probably convey a portion of nourishment, though the great reservoirs are in the upper portion. The most singular part of the worm is what may be considered as its uterus. Just below the depressed band a white vessel is seen, which soon divides into two, and after running some way in a cylindrical form, they quickly become smaller, and at last are minutely convoluted, embracing on all sides the intestinal tube. These vessels, forced by the agonies of the worm through the particles of the abdomen, appeared to Mr. Church the young of the animal, which he, of course, considered as viviparous. It is, however, generally agreed that the *lumbricus intestinalis* is oviparous.

The *lumbricus terrestris* has but one vesicle, is flat towards the tail, and has bristles on its under side, which it can erect at pleasure. Its annular muscles are large, and of a dusky red; and on its under surface is a large semilunar fold of the skin, into which the animal can draw its head. It has also three lines on its upper surface.

The intestinal *lumbricus* is seldom solitary, but in very few instances appears to be injurious. Its source is unknown; for it has not been found in any other situation. When first discharged they are semitransparent, and of a dilute red colour, but they soon become yellowish. They are usually found in the jejunum and ileum, rarely in the large intestines, and still more so in the stomach. In each they appear to be escaping from the body, when fever renders their situa-

tion uncomfortable, or active anthelmintics force them with the mucus from their seats.

Lamarek *Système des Animaux sans Vertèbres; Histoire Naturelle des Vers*, par Deterville, (suite de Buffon); Pallas *de intra Viventibus*; Hooper's *Memoirs of the Medical Society*, vol. v. See VERMES.

LU'MBRICI LA'TI. See TÆNIE.

LUMBRICORUM SEMEN. See SANTONICUM.

LUMBRICUS TERRESTRIS. (See LUMBRICUS INTESTINALIS.) The EARTH WORM is supposed to have an antispasmodic and diuretic virtue. If worms are moistened with vinous spirits to prevent their putrefaction, and placed in a cellar, they deliquesce; and the liquor, when mixed with alkaline salts, is said to yield crystals of nitre. They have been employed for the same purposes as snails.

LU'MBRICUS E'DULIS. A species of *lumbricus* found on the southern sandy shore of Batavia, is considered as a delicacy; it is described by Pallas, who thinks it the same as the *teredo*, described in the twenty-sixth volume of the *Philosophical Transactions*. See *Spicilegia Zoologica Fasciculus*, x. 10.

LU'MBUS, (à *lubidine*). The LOIN.

LU'MBUS VE'NERIS. See MILLEFOLIUM.

LU'MEN, (quasi *lucimen*, à *luceo*, to shine). The effects of light on the human system have not yet been explained. We have of late only begun to perceive with clearness the causes of its influence on vegetables and some chemical preparations. We find, in general, that light separates oxygen; that it changes the nitric into the nitrous acid, and the oxymuriatic to common muriatic acid. We find, also, that it deprives many preparations of their peculiar colour, particularly phosphorus; and it seems greatly to influence the process of crystallization. Some preparations must be exposed to a strong solar light, as carmine; for a cloud, it is said, will spoil the colour, and the *argentum fulminans* requires to be exposed to the light of the sun for many days.

If we ascend to the vegetable kingdom, we shall find that the absence of light deprives the leaves of their colour; and Humboldt, who discovered some vegetables in the deepest shafts of mines, found that the shapes of the leaves were not the same. If plants, then, will grow without light, we must not consider their growth as wholly depending on the decomposition of water, in consequence of light; but we have reason to consider the colour as depending not only on the decomposition of the water, but of the carbonic acid gas also.

Animals confined without light are often of a white colour; but this must be confined to those who usually live in the open air; for the mole, the pangolin, and some others who scarcely ever see the day, are not white. The particular cause of this change has not been examined. It is not apparently from a deficiency of oxygen. Some animals emit light in their motions, and this light is connected with their life and activity, as in the *lampyris*, the glow worm, the insects in oyster shells, and those which illumine the sea in a storm. In these it seems that light enters into the composition of those fluids to which their activity is owing, and, indeed, every fact now noticed shows that light is a body, and may form a component part of other bodies. We are not acquainted with the effects of light on the human body. We know that the oxygen is a powerful

stimulus, and that colour, health, and vigour, are often in excess when this air is breathed; but it seems probable that this is the case when the oxygen is in a loose uncombined state, and that light is salutary in promoting its separation. These speculations are, however, uncertain, and it is still more so, whether light is really a component part of our bodies. When we reflect, however, that the general health is apparently connected with light, that the peculiar acid of the animal system, the phosphoric, has a powerful attraction for this element, and appears to contain it, not only in a chemical combination, but, when in the form of an oxide, unites with, and allows it to separate without decomposition, we may suspect it to be a more powerful agent in the animal economy than has yet been supposed.

For the physical properties of light, see Haüy *Traité de la Physique*, vol. ii.; Cavallo's *Natural Philosophy*, vol. iii.; and the article *Oculus*. For the chemical, see *Exeter Essays*.

LU'NA, (from the Hebrew term *lun*, the night). See ARGENTUM.

LU'NA PHILOSOPHO'RUM. See ANTIMONIUM.

LUNA'RE OS, (from *luna*, the moon). The second bone of the first row in the wrist, because one of its sides resembles a crescent. See CARPUS.

LUNA'RIA, (from *luna*, the moon; from the shape of its leaves, like a crescent). An appellation of many plants whose leaves are reniform, but more peculiarly applied to the *osmunda* of Linnæus.

LUNA'RIS PILU'LA, (from *luna*, silver). See CAUSTICUM LUNARE, under ARGENTUM.

LUNA'TICA, ISCHU'RIA, (from *luna*, the moon). A periodical suppression of urine, noticed by Sauvages. See ISCHURIA.

LUNE'TRIA is, in the chemical jargon, a species of hectic, curable in one period of the moon.

LUPA'RIA, (from *lupus*, a wolf; supposed to destroy wolves). *Aconitum Ponticum folio Platani*, *Lycocotonum luteum*, *aconitum lycocotonum* Lin. Sp. Pl. 750. YELLOW WOLF'S BANE. Like the other species, it is poisonous.

LU'PIA (from *λυπιω*, to molest). A kind of tumour like a ganglion, hard, and not peculiar to any part of the body: when it is in the inside of the eyelid it is called *chalaza*; when about the joints *lupia*. Dr. Cullen uses it as a generic term for wen. See NÆVUS.

LU'PULUS, (*λυπη*, dislike; from its bitterness,) *humulus convolvulus perennis*, *humulus lupulus* Lin. Sp. Pl. 1457. The HOP. This plant hath hollow stalks, and broad serrated leaves, cut into three or five sharp pointed sections. On the tops grow loose scaly heads, among which are small flat seeds. It is perennial, grows wild in hedges, and the bottom of hills, in various parts of Europe; but those used are cultivated in plantations. In August and September the scaly heads are dried in kilns with a gentle fire.

The scaly heads have a bitter, warm, aromatic taste, yielding their virtue to proof and rectified spirit, by maceration without heat; and to water, by warm infusion. The extract obtained from the spirituous tincture is an elegant bitter; but hops are only at present used for preserving malt liquor. Like many other bitters, the cold infusion is more grateful than that made with boiling water; but the quantity must be larger. Hops have

been suspected of a narcotic power, and there is said to be an act of parliament prohibiting their use in beer. On the other hand, a pillow of hops has been said to procure sleep. Hops have been lately, like other narcotic bitters, recommended in gout. The Spaniards boil a pound of hop roots in a gallon of water to six pints, and drink half a pint of the decoction, whilst in bed, every morning, as a remedy for the lues venerea. See Lewis's *Materia Medica*.

LUPUS. THE WOLF CANCER; because it devours rapidly the flesh, like a wolf. It is the *noli me tangere* in the seventh order *tubercula* of Willan. See CANCER.

LU'PUS PHILOSOPHO'RUM. See ANTIMONIUM.

LUSCIO'SUS, and LUCI'TIOSUS, (from *luscus*). One who only discerns objects that are very near the eye. See NYCTALOPS.

LUSITA'NICUM DECO'CTUM. See Sarsaparilla.

LUTE'A, LUTE'OLA, (from *lutum*, mud; because it grows in muddy places, or is of the colour of mud,) *struthium*, DYER'S WEED. *Reseda luteola* Lin. Sp. Pl. 643. The root, boiled with salt, dyes wool of a fine yellow colour. Dioscorides recommends it as useful in the jaundice, and, indeed, every thing yellow was employed in the same disease; but the present practice does not notice it.

LUTUM, (from *λυος*, soluble). LUTE. CEMENTUM. Many chemical vessels require to be covered with coating, to preserve them from being broken or melted in the fire, or to close exactly their junctures. These coatings are, in general, called *lutes*. Glass vessels may be covered with a mixture of equal parts of coarse sand and stiff clay, mixed with water and a little hair, so as to form a liquid paste, which must be spread with a brush upon the glass; and when dry, covered with another coat, until the covering is sufficiently thick. When a glass is to be exposed to the action of the fire, a coating of fat earth and fresh horse dung is recommended: the earth is suffered to macerate for some hours in water; and, when properly softened, it must be kneaded with the horse dung into soft paste, to be spread with the hand upon every part of the retort. The horse dung is useful, as containing a serous fluid, which hardens by heat, strongly connects all the parts together, and with filaments of hay, contributes to cement them very firmly. The dung must be fresh: for, when altered by fermentation, it does not possess the same virtues. Retorts, luted in this manner, resist the action of the fire very powerfully, and the adhesion of the lute is such, that, even should the glass break during the operation, the distillation may be still carried on.

The lutes with which the joining of vessels are closed are of different kinds, according to the nature of the substances to be distilled. When vapours of watery liquors, and such as are not corrosive, are to be prevented from escaping, it is sufficient to surround the joining of the receiver to the nose of the alembic, or of the retort, with slips of paper, or of linen covered with a mixture of wheat flour and water, of the consistency of soft paste; slips of bladder, wetted, will be often sufficient if carefully applied. When more active vapours are to be secured, the lute may consist of a soft paste made of quick lime extinguished in air, and mixed with the white of egg. When corrosive acid vapours

are to be confined, what is called the fat lute is necessary. Fine clay, well dried and powdered, must be sifted through a silken searce, then moistened with water, and beat into a stiff paste with boiled lintseed oil, applied to the junctures, and secured by means of slips of linen: these slips must be covered with the lute made of quenched lime and white of egg. Chaptel's Elements of Chemistry.

LUXATIO, LUXATURA, (from *luxo*, to dislocate). *Dislocatio; aberratio; eluxatio; emotio; elongatio; ectotoma; ecclysis; lygismos; delocatio; exarthrema; olis-thema*; a LUXATION, or DISLOCATION. A slight dislocation is termed *diactnema; pararthrema*; an incomplete one, *contortio* or *declinatio*. Dr. Cullen places it in the class *locales*, and order *ectopice*, which he defines a bone removed from its seat in the joints. To which may be added, "causing an impediment to voluntary motion:" a compound luxation is when a wound, fracture, or a violent contusion, attends.

Luxations from internal causes are thus distinguished: 1. The limb is so relaxed, that it may be easily moved in any direction. 2. A cavity about the joint, and a hollowness between the bones, may be felt with the fingers. 3. The dislocated bone, if replaced, soon escapes spontaneously, from the weakness of the ligament and muscles. 4. The dislocated limb is frequently longer than the sound one, and attended with neither pain, inflammation, nor convulsion. 5. It generally happens to the upper part of the femur, or humerus, and sometimes to the articulation of the foot with the tibia. When owing to an external injury, the diagnostics are uncertain, when the joint is swollen from a violent contusion or distortion. In such cases we must suspend our judgment; and could we decide until the inflammation and tumour were abated, attempts towards a reduction would be improper. The more readily to discover a luxation, it may be observed, that when the head of a bone is removed out of its place, the other end will be distorted in an opposite direction. A tumour is also generally observable where the dislocated part of the bone is seated, and an hollowness from whence it receded; though, in a muscular part, the tumour and cavity are not easily perceived.

In consequence of a luxation, the symptoms differ as the parts affected are different: in general, there is an immobility, or a defective motion of the dislocated limb; a distraction of some muscles, and a relaxation of others; violent pain and inflammatory tension of the joint; a torpor of the subjacent parts; a compression of the neighbouring vessels, from whence an atrophy, gangrene, pain, œdematous swellings, or convulsions, may ensue.

Compound luxations are more dangerous than compound fractures. Boerhaave observes, that the worst luxation is produced by a solution or a separation of the epiphysis from the body of the bone. In general, the prognostic should be cautious, but the difficulties and uncertainties are greater in proportion to the distance of the dislocated bone from its proper place; the figure of the luxated limb; the part in which the luxation is seated; the parts pressed, or intercepted; the pain, inflammation, or other violent symptoms.

It will be obvious that a partial dislocation may be more easily reduced than a more complete one; and a fracture attending will render the cure more doubtful:

indeed, if a fracture near the joint is accompanied with a luxation, a stiff joint must be expected, if the limb can be saved. After a limb has been some time luxated, it forms a socket for itself, and its old cavity is usually filled with a fatty substance, but not with inspissated synovia, as has been asserted. The attempt is, in this case, hopeless, and generally unnecessary; for the limb, in its new position, retains some degree of motion, and is perhaps more serviceable than it would be after the inflammation which would arise from unsuccessful attempts. In delicate constitutions, and advanced periods of life, luxations are more easily reduced than in the young and strong, whose muscles resist very powerfully.

The object of the surgeon is to reduce the luxation, an operation called *embole*; and to retain the limb in its proper situation. If inflammation or tumour is considerable, they must be removed before a reduction is attempted. Mr. Pott justly observes, that the resistance of the muscles is the only cause of the difficulty of reducing luxations; that much force is never required, provided the muscles are relaxed by a proper position of the limb; and that in recent cases, at least, the capsular ligament will rarely, if ever, impede. The extension should be gradual and continued, until the dislocated bone is on a level with the cavity from whence it receded. If the head does not then spontaneously return, it must be assisted by pressure, employing the dislocated bone as a lever. Dr. Hunter seems to think that a rupture of the capsular ligament is a greater impediment to reduction than the contraction of the muscles. It cannot be denied, that, in violent luxations, this ligament is often broken; but this is by no means an universal consequence. Both recommend gentle extension, and to avoid violence.

When the external parts are violently bruised, general and topical bleeding, saturnine applications, &c. are necessary. The limb must be laid in an easy posture, and the tumour allowed to subside before the real nature of the case can be understood, or any attempt made to reduce the displaced bone. The great impediment, we have said, is the strong power of the muscles, which not only resists the extension, but often throws the bone into a different cavity from that to which we wished to direct it. When a fracture accompanies dislocated bones, a firm callus must be allowed to form before the reduction is attempted; but, if the fracture be at a distance from the dislocation, or in very small bones, where the power of the muscles is inconsiderable, this precaution may be neglected.

After the luxation is reduced, leeches and saturnine applications should be employed, the pains moderated by opium, and fever diminished by cooling medicines, laxatives, and a low regimen in every respect. The most perfect tranquillity is absolutely necessary.

1. CA'LCIS LUXATIO O'SSIS. *Luxation of the heel bone.* Whether luxated inward or outward, a cavity on one side, and a tumour on the other, discovers it; and the pain is severe. The treatment is the same as is directed when the bones of the hand are luxated.

2. CA'PITIS LUXATIO VCL CRA'NIJ. *Luxation of the head.* A separation of the bones of the cranium from the hydrocephalus is by some called a luxation of the head; but in general, is meant a luxation of the upper vertebra of the neck. In this case, the patient

being seated upon the ground, and supported by an assistant, the surgeon standing behind should raise the head from the breast. The assistant should press down the shoulders, and the head be gradually drawn up, till the dislocation is reduced. If this does not happen with moderate extension, it may, at the same time, be gently moved from side to side. A sudden crack or noise is heard on the reduction being completed. See Bell's Surgery, vol. vi. p. 183, 195.

3. CA'RPI LUXA'TIO. *Luxation of the wrist.* One or two of the bones in the wrist are sometimes removed from their place, which is discovered, as usual, by a tumour and a cavity, with violent pain. If the luxation is recent, it must be treated as a luxation of the hand. Bell's Surgery, vol. vi. p. 89, 246. White's Surgery, p. 163.

4. CLAVI'CULE LUXA'TIO. *Luxation of the clavicle.* When this accident happens, the sooner the reduction is performed the better; for long continued luxations of the clavicle are rarely cured.

The clavicle may slip from the sternum either outward or inward; in the first case a preternatural tumour is observed about the joining of the bones: in the latter case a sinus is observed in the part affected, the aspera arteria, the carotids, the contiguous nerve, and the œsophagus, are compressed. The general directions recommended, in case of a fractured clavicle, when the accident hath happened near the breast bone, are sufficient in this as well as with respect to a luxation happening next the acromion. The last is sometimes not easily distinguished from a luxated humerus. Paré observes, that in this case the upper part of the clavicle starts upwards, and a hollow cavity is observed where the clavicle is separated from the acromion: the pain is violent, and the patient cannot move the arm upwards. If the reduction is not speedily effected, the arm will soon become paralytic.

The greatest care is required in the use of bandages, lest a stiff or a luxated arm should remain. If the bone is luxated near the sternum, and is started outward, besides bolsters to depress the end of the bone, the capeline bandage should be applied; but if inward, the stellate bandage is preferable, on account of its keeping the shoulder back. If the luxation is next the scapula, the spica with two heads may be used. If both clavicles are displaced, the double spica must be employed, as directed in luxations of the humerus and scapula. See Bell's Surgery, vol. vi. p. 204; White's Surgery, p. 157.

5. CO'CCYGIS O'SSIS LUXA'TIO. *Luxation of the os coccygis.* This bone may be forced inward by a blow, or outward by a difficult birth. In this case, the pain is felt in the lower part of the spine, and inflammation, sometimes with suppuration, in the rectum, is produced. Independent of these symptoms, the sight and touch will discover the disease. In the latter case the bone may be replaced by pressure with the thumb: in the former the fore finger dipped in oil must be introduced up the anus, to press the bone outward, while the other fingers, applied externally, guide it to a proper place.

The T bandage is necessary, and the patient must be kept in bed; and, when he rises, sit in a perforated chair. See Bell's Surgery, vol. vi. p. 201; White's Surgery, p. 157.

6. CO'LLI LUXA'TIO. *Luxation of the neck.* A luxation between the head and the upper vertebra of the neck is immediate death, from the pressure on the medulla oblongata, or medulla spinalis. When a man is said to have broken his neck, there is a partial luxation of the first or second vertebra only; and in this case the chin is fixed to the breast, which prevents his speaking, swallowing, or moving the parts below. If an assistant is at hand, he must follow the directions given for the luxation of the head; or, to gain more power, he should immediately turn the patient on his back, and setting his feet against his shoulders (being, himself seated on the ground), place his hands below the patient's ears, and draw the head towards him, gradually increasing the force with which he pulls, and, in pulling, move the head from side to side.

After reduction, the part should be bathed with spirit of wine. White's Surgery, p. 186.

7. COSTA'RUM LUXA'TIO. *Luxation of the ribs.* If a rib is forced inwards, the pleura is injured, and excruciating pains, inflammation, difficulty of breathing, cough, ulcers, and immobility of the body, follow. These complaints, with the external appearance of the side, evidently discover the misfortune. This luxation happens between the rib and the spine.

Luxations internally are with difficulty reduced, because neither the hands nor any instrument can be applied to elevate them. The patient may be laid on his belly over some cylindrical body, and the anterior part of the rib being moved gently towards the back, or shook a little, the head may probably recover its situation. If this fails, the method proposed for fractures of the ribs, when they are forced inwards, and a splinter offends the pleura, may be employed. But, if the symptoms are not urgent, nor the heads of the ribs much removed, every violence should be avoided, as luxated ribs have often remained so without danger.

The bandage should be a napkin and scapulary, and compresses squeezed out of camphorated spirit of wine applied. See Bell's Surgery, vol. vi. p. 208.

8. DIGITO'RUM MA'NUS LUXA'TIO. *Luxation of the fingers.* The joints of the fingers may be luxated in every direction; but an easy extension, and gentle pressure with the finger and thumb will readily reduce them. See LUXATIO METACARPI 16; Bell's Surgery, vol. vi. p. 249; White's Surgery, p. 163.

9. DIGITO'RUM PE'DIS, et O'SSIUM PE'DIS LUXA'TIO. *Luxation of the toes and bones of the feet.* A dislocation of these bones produces great pain, inflammations, and sometimes convulsions, if speedy assistance is not obtained. They are reduced as directed in the case of bones in the hand being the subjects of this accident. The toes are treated as directed for the fingers. See White's Surgery, p. 167.

10. FE'MORIS O'SSIS LUXA'TIO. *Luxation of the thigh bone.* A fracture of the neck of this bone is sometimes mistaken for a luxation. The head of the thigh bone may be luxated downwards, forwards, inwards, outwards, and backwards. This luxation, like that of the humerus, is always perfect, and most frequently happens inward and downward, the head of the bone tending towards the large foramen of the os pubis.

When the luxation is outwards, the bone generally slips upwards at the same time; if inwards and down-

wards, the leg is longer and more bent than the other, and the knee and foot turn outwards: the head of the bone is thrust near the lower part of the inguen and the foramen of the os pubis; sometimes the pressure of a nerve, which communicates with the bladder, or of the crural, causes a suppression of urine, or a numbness in the leg. A hollow cavity is perceived in the buttock, usually filled by the great trochanter; and if the reduction is long neglected, the limb withers. The patient will be always lame; the knee of the luxated limb cannot be brought to the other; and the chief pain will be felt in the groin, without the grating observed when the bone is fractured, on moving the limb. If the luxation is backwards, the limb is drawn upwards, and a cavity is perceived in the groin, with a tumour in that part of the buttock where the head of the bone and the trochanter are lodged. The limb is shortened, the foot bends inward, the heel does not touch the ground, but the patient seems to stand on his toes, and the luxated limb is more easily inflected than extended: in this case, many stand and walk firmly without the bone being reduced, provided their shoe has a higher heel.

A fractured neck of the thigh bone is distinguished from a luxation of its head, when the thigh bone is luxated by an abscess, without any external violence, but only by walking or rising up; when unattended with pain, tumour, or inflammation; or when the whole limb may be bent, and turned about the acetabulum without the noise usually heard in fractures: the contrary signs indicate a fracture.

In reducing the luxated head of the thigh bone, a longitudinal extension will not suffice, but it must be according to the direction of the cervix. "When a thigh is dislocated inward, or outward, follow," says Mr. Kirkland, "Celsus's advice in laying the patient on one side, so that the part into which the bone hath slipped be always uppermost, and that from which it hath receded, lowermost; by which means the extension may be made in any direction you have a mind, and your own invention will point out to you twenty ways of securing the patient upon a bed (for a table is usually too high), so that a proper resistance be made to the extension. This done, the knee bent, and a towel fixed properly above it, you must place yourself on that side of the thigh to which the bone is dislocated, with your knee near the head of the bone, and both hands on the opposite side of the knee of the patient, an assistant being fixed at the ankle. The extension may then gradually be begun by three or four men, with the thigh rather in a state of flexion; and when there is reason to think that the head of the bone is brought to a level with the socket, the extension being steadily continued, the knee may be bent near to the abdomen, and, at the same time, whilst the knee pushes the bone towards its place, the ankle must be moved in the same, but the knee of the patient in a contrary, direction. Thus the head will always go into the socket, provided a due extension is made before you attempt to return it."

Sometimes the head of the thigh bone is pushed between the ischium and sacrum; in this case, except the patient is exhausted, before attempting the reduction, it will be most eligible to reduce him by brisk cathartics, given at short intervals; for the case, in this way, is better ascertained, and the reduction more easily ef-

fect. London Medical Journal, vol. v. p. 412; Bell's Surgery, vol. vi. p. 252; White's Surgery, p. 163; Edinburgh Medical Commentaries, vol. ii. p. 40.

11. FI'BULÆ LUXA'TIO. *Luxation of the fibula.* This bone may be separated from the tibia, either at the lower or superior part. In the former case it generally proceeds from a luxation of the foot externally; this bone must, therefore, be reduced, bound up, and the case treated according to the directions given for luxations of the knee and patella. See Bell's Surgery, vol. xi. p. 273.

MALLE'OLI LUXA'TIO. *Luxation of the ankle.* See N^o 21.

12. GE'NU LUXA'TIO. *Luxation of the knee,* is usually partial. If complete, it is easily reduced, but cannot be retained, because the cross ligaments are broken. A luxated knee pan is a necessary attendant of a luxated knee, and often taken for it; but in a proper luxation of the knee the tibia recedes from the femur, either backwards or to either side, but never forward, because the patella hinders it. In this part dislocations are easily discovered.

If the luxation is partial, the patient must be placed on a table, one assistant taking hold of his thigh, and another extending his leg; in the mean time, the operator may reduce the bone with his hands. In children and young persons, if the extension is made with violence, it endangers a separation of the epiphyses, a worse disease than the luxation. See Bell's Surgery, vol. vi. p. 269; White's Surgery, p. 165.

13. HU'MERI LUXA'TIO. *Luxation of the humerus.* The head of this bone may slip out before, behind, (even under the scapula,) or downwards; but never upwards, except the acromion and coracoid processes are fractured. When the humerus is luxated downward, there is a cavity in the upper part of it perceptible to the eye in some instances, but to the finger in all, and a tumour in the arm pit, because the head of the bone is lodged there. The luxated arm is longer than the other, and when it can be moved or extended, it gives exquisite pain in lifting it to the mouth.

Fresh luxations are most easily reduced; those of long continuance are restored with difficulty; but if the head of the humerus adheres to the adjacent parts, which after a long time usually happens, a reduction cannot be effected by any means. See Medical Observations and Inquiries, vol. ii. p. 340.

To reduce the humerus, bend the fore arm, and let an assistant support it; then elevate the arm so that the elbow may be advanced somewhat above the shoulder, bringing it a little inward. An assistant must then make the extension, whilst another counteracting him, draws the inferior angle of the scapula backward toward the spine, and presses the acromion a very little downwards: the operator, with his fingers in the axilla, presses the head of the bone upward as soon as he perceives the extension to be sufficiently made, and at the same time, with his other hand, brings the elbow of the luxated arm to the patient's side. An extension made downwards, or even horizontally, more frequently fails, than when it is made in some degree upward.

When the luxation is forward, that is, when the head of the humerus is under the pectoral muscle, there is a cavity under the acromion, but the head of the luxated bone projects towards the breast more than when in the

axilla; and if the arm be moved, a more acute pain is felt than in the preceding case; for the great artery and the nerves of the bones are much pressed. If this luxation is not easily reduced by the method directed, when the head of the humerus is in the arm pit, let a pulley from the top of a room be fastened to the luxated arm, just above the elbow, and the patient gradually raised from the ground by it: this at least brings the head of the humerus into the axilla, and it may be restored into its proper place by the means just described. In this process the fore arm must be brought toward the breast, that the muscles may be relaxed.

If the luxation is backward, the elbow approaches the chest, and the head of the bone is prominent on the outside of the shoulder; the arm cannot be moved from the breast, nor extended without great agony, and the lower angle of the scapula will be somewhat pushed out. In this case the general process may be the same as when the head of the humerus is under the pectoral muscle.

If there is no pulley, a tall strong man may take the patient's arm over his shoulder, and gently raise him from the ground, and the operator may push the head of the dislocated bone into its place as the body becomes suspended. This method of suspending the patient is not so severe as it may seem; for as no force is used about the shoulder to make a counter extension, the patient does not suffer from those troublesome excoriations and contusions which too commonly attend the other methods.

It is generally agreed that machines for reducing a luxated humerus are never needful. Freke's command-eris preferred to all the other instruments used for this purpose; as in the use of it the limb may be moved in all directions during the extension, and the situation of the head of the bone can be examined; but great care is required to keep it perpendicular to the side of the patient.

As in other luxations, bleedings, &c. to prevent or check inflammation and swelling, must be used after the reduction, and the arm suspended by a sling. See *Medical Observations and Inquiries*, vol. ii. p. 373; *Bell's Surgery*, vol. vi. p. 211; *White's Surgery*, p. 158.

14. *MANUS LUXATIO*. *Luxation of the hand*. The hand may be luxated backward, forward, and on each side; but a luxation backward or forward is most frequent. Each accident is readily distinguished.

From the distortion of the strong ligament, and the pressure on the tendons, there is exquisite pain and a rigidity of the fingers; and inflammation, tumour, abscess, gangrene, and a caries of the spongy bones of the carpus often follow, seldom curable but by amputation. A recent inconsiderable luxation is more easily managed, and it should be speedily reduced, by extending the hand and arm in opposite directions; and by placing the cavity of the extended hand on a table or some other flat body, that the tumour may be depressed. This method is necessary, whatever part of the hand is luxated. See *LUXATIO METACARPI*, 16.

15. *MAXILLÆ INFERIORIS LUXATIO*. *Luxation of the lower jaw*. This bone is usually luxated forwards on one or both its sides. If one side only is luxated, the chin inclines to the opposite side, and on the dislocated side the mouth is wider open. When both sides are dislocated, the mouth gapes wide, the jaw starts

forwards, and the chin falls towards the breast, so that the patient cannot shut his mouth, speak distinctly, nor swallow with ease. This accident may happen from a blow, or from yawning.

When one side only is dislocated, it is easily reduced; but when both sides suffer, the patient must be placed in a low seat, with his head secure against the breast of an assistant; then securing the thumbs from being bit, place them on the patient's teeth, as far back as you conveniently can, at the same time fixing your fingers on the outside of the jaw: when you have secure hold of the jaw, press it downward, backward, and upward. If all this is done almost in the same instant, the reduction will be complete; or, as Mr. Bell says, when the fingers are applied as directed, the surgeon must pull the under jaw forward, till he finds it move somewhat from its situation; and he should then press the jaw forcibly down with his thumbs, and moderately backward with the palms of his hands, when the ends of the bone will immediately slip into their situation.

If only one side is luxated, the same mode will succeed, if the affected side be pressed most forcibly downwards and backwards. Bandages are useless in this case. See *Bell's Surgery*, vol. vi. p. 189, 190; *White's Surgery*, p. 155.

16. *METACARPI LUXATIO*. *Luxation of the Metacarpus*. See *MANUS LUXATIO*.

Mr. Bell observes, that in the reduction of these dislocations (viz. of the metacarpus and fingers), the bone should not be pulled down till it be somewhat raised or elevated from the contiguous bone; for, as all the bones of the fingers and thumbs, as well as those of the metacarpus, are considerably thicker at their extremities than in any other part, these projections are apt to be forced against each other when the extension is made in a straight direction. See *Bell's Surgery*, vol. vi. p. 249, 251; *White's Surgery*, p. 163.

17. *NA'SI O'SSIS LUXATIO*. *Luxation of the bone of the nose*. This accident is easily discovered by the eye and the touch. The reduction is effected by a quill put up the nostrils, and then, with the fingers replacing the bones. After the reduction a sticking plaster may be applied. *Bell's Surgery*, vol. vi. p. 184.

18. *OLECRANI LUXATIO*. *Luxation of the elbow*. A perfect luxation of this joint rarely happens, except the olecranon is fractured, or the ligament greatly weakened. This luxation may be backward (which is most frequent), forward, outward, or inward. If backward, the arm appears crooked and shorter, and cannot be extended: in the internal part of the flexure the humerus will be prominent; in the external, the olecranon, with a large cavity between both bones. When from the fracture of the olecranon, the elbow is pushed forward, the os humeri will stick out behind, the ulna is prominent on the fore part, and a cavity appears in proportion to the luxation. If external, the tumour is so too, and vice versa.

In a violent luxation, or one of long standing, the bone cannot be replaced without great difficulty, as the ligaments are strong and the processes numerous. Recent and slighter luxations are more easily restored.

If the ligaments and tendons are rigid, emollient applications should be used some time before attempting the reduction; the egg liquor is useful in this case. See *ANCHYLOSIS*.

In reducing this luxation an extention must be made, until the fore arm can be bent; and then the reduction is easily accomplished by bearing upon the lower end of the humerus with one hand, and by taking hold of the wrist and bending the elbow with the other. If it is on either side, the hand of the patient must be turned inward or outward, at the same instant, as the case requires. After reduction, the arm should be hung in a sling for some time, that the parts may recover their tone. See Bell's Surgery, vol. vi. p. 239. White's Surgery, p. 162.

19. PATE'LLÆ LUXA'TIO. *Luxation of the knee pan,* may happen externally and internally. In order to its reduction, the patient's leg must be pulled straight, or if he can, he may stand on it erect; then the operator, taking firm hold of the patella with his fingers, may force it into its place. Nothing but rest is afterwards required. Bell's Surgery, vol. vi. p. 267. White's Surgery, p. 165.

20. PE'DIS O'SSIUM LUXA'TIO. See 9.

21. TA'LI LUXA'TIO, seu MALLE'OLI. *Luxation of the ankle.* Dr. Hunter observes, that when there is a luxation of the malleolus internus, there is generally a fracture of the fibula; but that if the person is of a weak constitution, ligaments may be relaxed without a fracture.

If the ankle is luxated inwardly, the bottom of the foot turns outward; if outwardly, the contrary. If forward, the heel becomes shorter, and the foot longer than usual; if backwards, the heel is lengthened, and the foot shortened. This kind of luxation is usually attended with great pain, and other very violent symptoms; and the difficulty of reducing the ankle is proportioned to the violence of the cause. The patient should be placed on a table or bed, and the leg, with the knee bent, firmly secured by an assistant or two. The foot is now to be put into that situation which tends most effectually to relax all the muscles which belong to it; and an assistant must be desired to extend it in that direction till the most prominent point of the astragalus has clearly passed the end of the tibia, when the bone will slip, or may be easily forced into its place. The patient should keep in bed until the fever and the symptoms of irritation leave him, and he is in some measure able to rest upon his ankle. See Bell's Surgery, vol. vi. p. 274. White's Surgery, p. 166.

22. VERTEBRARUM LUXA'TIO. *Luxation of the vertebræ.* The vertebræ are rarely perfectly luxated. Those of the neck and loins are more subject to this accident than those of the back, because they are more moveable and smooth, are destitute of those cavities with which the vertebræ of the back are furnished, and have a thicker cartilage interposed betwixt each. Luxations of the vertebræ must be imperfect, unless attended with a fracture, and a laceration of the spinal marrow, an accident quickly fatal. The imperfect luxations are scarcely less fatal; and they most frequently happen in the upper vertebræ of the neck. Dislocation or crookedness of the dorsal vertebræ sideways, is called *contortio*.

The vertebræ of the back cannot move in any great degree without a fracture: their upper or lower apophyses, and sometimes only one, is misplaced; for great violence is generally required in order to a partial luxation. When a vertebræ is luxated without a fracture,

the body leans to one side, or forward: if the left side is affected, the patient leans to the right, and vice versa.

The common signs of a luxation of the vertebræ in the back are, that the back is crooked and unequal; the patient can neither stand nor walk, and his whole body seems paralytic; all the parts below the luxation are insensible and immovable; the excrements and the urine are retained, or discharged involuntarily; the lower parts mortify, and the patient soon dies.

All the luxations in the spine are very dangerous, from the injury done to the spinal marrow, and the difficulty of reducing them. The danger is also greater, the nearer the luxation is to the head; as from the vertebræ of the neck and back, the nerves which supply the heart and intestines are chiefly derived. When several vertebræ are luxated, the bad symptoms are not so violent.

For reducing the vertebræ of the neck, see COLLI LUXATIO. When both the apophyses of the vertebræ are dislocated, the patient must be laid on his belly over some round body, and two assistants may depress both ends of the luxated spine on each side, which elevates, and gradually extends the vertebræ, the spina dorsi being thus bent in form of an arch. The surgeon next presses down the inferior dislocated and prominent vertebræ, and, at the same instant, expeditiously pushes the superior part of the body upwards. If the first attempt fails, it must be repeated two or three times. When the left apophysis only is displaced, after the patient is laid in the same posture, one assistant may depress the left coxa, and the other the right humerus; and the reverse, if the injury is on the other side. After the reduction, it may be necessary to take some blood, and compresses wrung out of spirit of wine should be applied, and then the napkin and scapulary. See London Medical Journal, vol. i. p. 326, 327. Bell's Surgery, vol. vi. p. 196; and White's, p. 156. Boerhaave's Aphorisms. Petit's Diseases of the Bones. London Medical Observations and Inquiries, vol. ii. p. 99, &c. Gooch's Cases and Remarks. Pott's General Remarks on Fractures and Dislocations. Kirkland's Observations on Pott's Remarks. Medical Museum, vol. ii. p. 406. Heister's, Wiseman's, Bell's and White's Surgery.

LUXURIANS, (from *luxurio*, to exceed). A flower is called luxuriant, when the teguments of its fructifications are augmented so as to exclude some other essential part. Double flowers, which are luxuriant ones, seldom produce fertile seeds.

LYCAN'NCHE, (from *λευκος*, a wolf). A QUINCY; because the noise in breathing is supposed to resemble the howling of a wolf. See ANGINA.

LYCANTHRO'PIA, (from *λευκος*, a wolf, and *ανθρωπος*, a man). LYCANTHROPY; by the Arabians *cutubuth*, from an animal which perpetually moves up and down on the surface of stagnant waters; by Ætius, *cynanthropy*, as well as *lycanthropy*. It is supposed to be the disorder with which the demoniac, mentioned in scripture, who dwelt among the tombs, was affected. Oribasius informs us, that persons affected with this disease "leave their houses in the night time, in every thing imitate wolves, and wander about the tombs until break of day." Actuarius adds, that "they then return to their homes and their senses." Their looks are said

to be pale, their eyes dull, hollow, fixed, dry, and without the moisture of a tear; their tongues dry, their legs, from the bruises they receive in the night, (and, according to *Ætius*, from the bites of dogs,) full of incurable ulcers. It is the *melancholia errabunda, erratic melancholy* of Sauvages. Bleeding, blisters, purgative medicines, interposing anodynes, with gentle treatment, are the principal means of relief.

LY'CHNIS, (from *λυχνος, a torch*, because its leaves were usually rolled up as torches).

LY'CHNIS SE'GETUM MA'JOR. See NIGELLASTRUM.

LY'CHNIS SYLVE'STRIS. See ANTIRRHINUM, OCIMASTRUM, BEHEN ALBUM VULGARE, and SAPONARIA.

LY'CHNIS VISCO'SA RU'BRA. See MUSCIPULA.

LY'CHNIS CORONA'RIA DIOSCORIDIS, ROSE CAMPION, is cultivated in gardens, flowers in June, and its seeds are cathartic.

LYCHNOIDES SE'GETUM, (from *lychnis*, and *ειδος, likeness*). See NIGELLASTRUM.

LY'CIA. See CERUS CYPRI FOLIO.

LY'CIUM, (from *Lycia*). The *nandia agriahalid, arbor spinosa*, the INDIAN THORN, probably a species of *prunus*, grows in the East Indies, is very large, resembling the wild pear; fruit bitterish and styptic; the leaves sour and astringent. This last property its inspissated juice preserves, and is called *cate*, as it is mistaken for the terra Japonica.

LY'CIUM BU'XI FO'LLIIS, *pyracantha*, BOX THORN. *Celestrus buxiformis*, or *pyracanthus* Lín. Sp. Pl. 285, grows in hot countries. The rob of the fruit is astringent, but it is often adulterated, or the rob from the berries of *periclymenum* substituted for it.

LYCOCTONUM, (from *λυκος, a wolf*, and *κλεινω, to slay*, because it was used for the purpose of destroying wolves). See ACONITUM.

LYCOPE'RDON, (from *λυκος, a wolf*, and *περδον, crepitus*). PUFF BALL, supposed to spring from the dung of wolves.

LYCOPE'RDON VULGA'RE, *crepitus lupi, bovista, orbicularis fungus rotundus maximus fulverulentus*; DUSTY MUSHROOM, PUFF BALL, *lycoperdon bovista* Lín. Sp. Pl. 1653, is round, or egg shaped, whitish, with a short and scarcely any pedicle, growing in pasture grounds. When young they are covered with tubercles on the outside, and pulpy within. By age they become smooth externally, and are filled with a fine light brownish dust. It is a very powerful vegetable styptic when externally applied. Gooch prefers it to the agaric of the oak, and every other fungous substance. It is softer and more absorbent than lint, and, if cut into slices, might answer the purpose of the sponge, recommended by Dr. Kirke-land, after amputation.

LYCOPE'RSICON, (from *λυκος, a wolf*, and *περσικον, a peach*, from its exciting a violent degree of lust). WOLF'S PEACH, *solanum peruvianum* Lín. Sp. Pl. 267. It partakes of the poisonous properties of the other solana.

LYCOPO'DIUM, (from *λυκος, a wolf*, and *πους, a claw*), *muscus clavatus, terrestris, squamosus, plicaria, cingularia*, WOLF'S CLAW, CLUB MOSS; *lycopodium clavatum* Lín. Sp. Pl. 1564, is a fertile moss, destitute of pedicles and capitella, differing from the selago, because its capsules, instead of being scattered in the sinuses of the leaves, are collected into a club; for each scale

covers a kidney shaped and bivalve capsule, which loses no part when ripe. It grows on heaths and hilly places, flowers in July and August, and is reckoned cooling and astringent. Its pollen is sprinkled with advantage on tender skins, to prevent excoriation. M. Bucholz, of the academy of Erfurth, has lately examined this singular substance, and found that the seeds contained one-sixteenth of a fat oil, of a brownish yellow colour, soluble in alcohol; a portion of true sugar; an insipid, viscid, brownish yellow extract, leaving a residuum of peculiar properties, not explained, but which is said to be a peculiar product of the vegetable kingdom. The yellowish appearance of the seeds is supposed to arise from their containing a pigment, and their oil occasions their inflammability and their separation from water. See PLICA POLONICA.

LYCO'PUS, (from the same). See MARRUBIUM AQUATICUM.

LY'DIUS LA'PIS, (from *Lydia*). See MAGNES.

LYGI'SMOS, (from *λυγιζω, to distort*). See LUXATIO.

LY'GMOS, (from *λυζω, to hiccough*). See SINGULTUS.

LY'MPHA, quasi *nymphæa*, (from *νυμφη, water*). LYMPH is a pellucid, insipid, pure liquor in the human machine, and the purer parts of the serosity generally obtain this appellation. The gelatinous parts of this fluid were supposed to nourish all the solids, its finer aqueous parts to be circulated through the lymphatic vessels, and, by means of the valves and conglobate glands, again conveyed to the heart. These ideas are, however, now exploded; but, in the Boerhaavian school, we still hear of lymphatic arteries, which are properly those which will not admit the red globules. They have corresponding veins distinguished by the same appellation. The source of the lymph, which we find in the cavities, as the pericardium, the ventricles of the brain, &c. either in the healthy state, or when accumulated in dropsical swellings, is uncertain. Dr. Hunter has attributed it to exudation through the inorganic pores, as he found his injections, the bile, and other fluids, exude after death. This opinion is, however, untenable, from many views, but particularly the numerous and dense coats of the vessels; for it is not probable that the pores should be sufficiently large for this purpose, without danger of all the serosity escaping; or that, in each coat, the inorganized pores should so minutely correspond. It is, therefore, with much reason, supposed that the exudation which he found was in consequence of the relaxation occasioned by death, and that all the watery fluids are either exhaled from the open orifices of arteries, or separated by a simpler species of secretion. There is, we think, little doubt of the vessels in a state of health confining the fluids by their tonic power. Indeed, they seem to pass off in a state of halitus.

LY'MPHÆ DU'CTUS, (from *lymphæa*, and *duco, to carry*). *Vasa lymphatica*. LYMPHATIC VESSELS. The lymphatics arise from the cells of the membrana cellularis, the cavities of the intestines, of the urine and gall bladders, and of every other viscus, carrying a pellucid liquor towards the receptaculum chyli and thoracic duct, in which they almost exclusively terminate. The coats of these vessels are thin and transparent, much

crowded with valves, so as, like the lacteals, to resemble, when injected with quicksilver, strings of beads. The lymphatics frequently anastomose, and in their way pass through the lymphatic glands, ramifying before they enter a gland, and uniting in their passage from it. *SEC LACTEA VASA, DUCTUS THORACICUS.*

The course of the lymph and of the chyle is from the extreme parts of the body towards the centre; and the lymphatics commonly lie close to the large blood vessels of the extremities. All the lacteals, and most of the lymphatics, open into the thoracic duct, which lies upon the spine, and runs up towards the neck, where it commonly opens into the angle between the jugular and subclavian veins of the left side; and thus both the chyle and the lymph are gradually mixed with the blood.

The coats of these vessels are thinner and more pellucid than those of the blood vessels, but stronger; for they can support the weight of quicksilver, which will rupture the coats of even the arteries. The internal coat is smooth, dense, and highly polished, projecting by little duplicatures into the cavity of the vessel forming the valves. The second coat consists chiefly of muscular fibres, running in every possible direction; but usually in a circular one, surrounding the internal membrane. The outward coat is similar to the pleura, or peritonæum.

The coats of the lacteal and lymphatic vessels have, in common with all other parts of the body, arteries and veins for their nourishment, and nerves for their animation: from the blood vessels running through them they are subject to inflammation, and, from their numerous nerves, they are more irritable than any other vessels in the human body. Their valves are two in number, of a semilunar shape; and are so frequently interposed, that three or four pair may be sometimes found in the space of one inch. They are occasionally fewer, and in some parts wholly wanting.

The lymphatics, like the lacteals, open into the cavities, and draw in the various fluids which these contain by a capillary attraction. It is probable, as we have said, that they convey fluids only, or solid substances very minutely divided. That they carry the bony matter we know, from the fact recorded by Mr. Cheston, where, in a case of mollities ossium, the thoracic duct was filled with an osseous matter. Bones are not, however, absorbed so rapidly as the frequently quoted experiment, with madder, would lead us to believe; for it is now found, that, though the colouring part of madder has a considerable affinity to the phosphat of lime, of which the bones consist, it has greater affinity to the serum of the blood. In such experiments the colouring matter is, therefore, only deposited, and again washed away, without any other corresponding change on the earthy salt. The fluids, when once absorbed, are carried, by the action of the vessel, or by the pressure of the adjoining muscles, beyond the first pair of valves; and, by the frequent recurrence of these valves, every action assists the progress of the fluid, since regurgitation is prevented. It is by no means certain that all the lymphatics pass into the thoracic duct. Some trunks have been discovered which escape it, and there is rather a probability that lymphatics occasionally terminate in veins farther distant from the heart.

Lymphatics, as well as lacteals, are not always excited to action: in other words, their extremities are not

erected so as to become capillary tubes, a circumstance depending on a variety of causes, of which we can perceive with distinctness only general debility, or a sufficient supply already in the system. We have had occasion also to suggest, that an elective affinity seems to influence the admission of some fluids, and the rejection of others. Perhaps sedatives may, for a time, paralyze the sensible orifices of the lacteals; stimulants excite them too violently, or astringents contract them too much. This may be deemed conjectural; but some facts might be adduced in favour of each supposition.

The lymphatic vessels of the lower extremities are the superficial, or those more deeply seated. The former lie between the skin and the muscles, and are connected with the surface, and the cellular membrane, which lies immediately under it, absorbing fluids from each; one branch of the superficial lymphatics runs upon the top of the foot, another generally under the inner ankle. The branch on the foot runs up on the outside of the tendon of the tibialis anticus, until it rises above the ankle; and running over the shin bone, it divides and forms a plexus, still ascending in the cellular membrane to the inside of the knee, from whence it advances up the inside of the thigh under the skin, and, arriving at the groin enters the lymphatic glands. These glands are seven or eight in number, some of which lie in the angle between the thigh and the abdomen, and others a little below on the fore part of the thigh. Into these upper glands only lymphatic vessels of the genitals enter, so that the venereal bubo, which arises in consequence of an absorption of matter from these organs, is always seated in these; and the lower glands are never affected, except from their vicinity to the glands first diseased. As the upper glands are affected from the genitals, so the lower are usually inflamed from the absorption of acrid matter in the parts below them. The lymphatic vessels of the genitals having joined those of the thigh, a net work is formed, which enters the abdomen under the edge of the tendon of the external oblique muscle, called Poupart's ligament: some branches of this plexus embrace the iliac artery. As no considerable branches can be distinguished on the outside of the leg or thigh, it is probable that all the lymphatic vessels of those parts bend towards the inside. Upon these superficial vessels, from the foot to the groin, there is scarcely in any instance one gland. Besides the superficial lymphatic vessels which lie above all the muscles, or in the cellular membrane under the skin, there is some seated amongst the muscles, accompanying the crural artery. Of these the principal trunk can be discovered by cutting down to the posterior tibial artery, near the inner ankle. From this part the vessel passes up with the posterior tibial artery, and is hid amongst the muscles on the back part of the tibia. About the middle of the leg it enters a small gland met with in most subjects, and from hence runs up to the back part of the ham, still lying close to the artery, and in the ham it usually passes through three glands. After it has passed these glands, this single vessel commonly divides into two or three branches, which still accompany the crural artery, and pass with it through the perforation in the triceps. Having passed the muscle, they go up with the artery and enter a gland deeper seated than those which appear on the groin, from which they pass into the superficial gland.

The lymphatics of the lower extremities having now reached the trunk of the body, and passed under Poupert's ligament, appear upon the sides of the ossa pubis, near the pelvis. Some pass up with the iliac artery upon the brim of the pelvis; and others dip into the cavity of the pelvis, and join the internal iliac artery near the sciatic notch. At this place they are joined by the lymphatics from the contents of the pelvis. Besides those which sink into the pelvis, on the inside of the external iliac, others keep on the outside of that artery upon the psoas muscle: of these a part goes up to the loins, and passing under the aorta in different branches, from the left side to the right, joins the thoracic duct. Another part passes under the iliac arteries, and appears upon the os sacrum, making a beautiful net work, joining the lymphatics of the right side, and passing under the iliac artery, to form the net work upon the upper part of the right psoas muscle. The lymphatic vessels of the right side, joined by some from the left, having reached the right lumbar region, appear there in the form of a plexus of large vessels, and pass through several glands. At this part, they receive likewise large branches under the aorta, from the plexus on the left side of the loins; and having at last got up as high as the second lumbar vertebra, they all join, and form a single trunk called the thoracic duct: at this part they are joined by the lacteals. See *LACTEA VASA*.

Into the thoracic duct the lymph from the other abdominal viscera enters. This is brought by a number of vessels, a plexus of which may be traced from each kidney, lying principally behind the emulgent artery, and opening into large lymphatic vessels near the aorta: these the lymphatics of the glandulæ renales generally accompany.

The lymphatic vessels of the spleen pass from the concave side of that viscus, along with the splenic artery in the sinuosity of the pancreas, by the lymphatic vessels of which they probably are joined.

To the stomach belong two sets of lymphatics, the one running upon its lesser, and the other upon its greater, curvature. The former accompanies the coronary artery, and passes through some lymphatic glands which lie by its side. The other set passes from the great curvature of the stomach, through some lymphatic glands that lie close to the arteria gastrica dextra. Descending by the pylorus, it meets the plexus that accompanied the coronary artery, and near the lesser curvature of the duodenum forms a considerable net work. Into this not only the lymphatics from the spleen enter, but likewise those from the gall bladder, together with those of the liver, which are very numerous both in its convex and on its concave side. Several branches proceed from this net work, some running under the duodenum, and others over it; which all open into the thoracic duct.

The lymphatics of the liver, the spleen, and the kidneys, are generally in two sets; one of which lies upon the surface of the organ, and the other accompanies the large blood vessels in its centre. In the liver, these two sets have been found to communicate with each other; so that, by injecting mercury into the lymphatic vessels which lie upon its convex surface, Mr. Hewson hath filled those which accompany the pori bilarii and vena portæ in its centre. Most of the lymphatic vessels

which lie upon the convex surface of the liver, run towards its falciform ligament, and pass down by the side of the vena cava; but some run towards the right ligament of the liver, where they pass down upon the diaphragm to reach the thoracic duct. The lymphatics on the concave surface run towards the porta, where they join those which come from the centre of the liver, along with its large blood vessels. The lymphatic vessels of the stomach enter with others into the thoracic duct. All the lymphatics of the viscera, with their different plexuses, are beautifully figured by Mascagni.

The lymphatics of the lungs are in two sets. One set passes on the posterior part of each lobe by its root into the thoracic duct, near the middle of the thorax; the other from the fore part of each lobe rises towards the jugular and subclavian veins. Some of the lymphatics, on the posterior part of the left lobe, creep under the aorta to the thoracic duct. Those from the anterior part of the left lobe proceed to the angle between the jugular and subclavian vein of the same side, joining the thoracic duct at its termination; while those from the fore part of the right lobe do not communicate with the thoracic duct, but pass into the angle between the right jugular and the right subclavian vein.

By the side of each internal jugular vein is a large lymphatic vessel, the trunk of those of one side of the head and neck. Smaller lymphatics are seen near the branches of the external carotid. From various circumstances, it is highly probable that there are lymphatic vessels on the external parts of the head; and though none have been discovered, on the brain also. The small lymphatics which accompany the branches of the external carotid artery unite upon the neck, and form a large trunk, which accompanies the internal jugular vein, passing through some lymphatic glands, near the termination of this trunk, in the angles between the jugular and subclavian veins. The glandula thyroidæa has many lymphatic vessels, which can sometimes be inflated by blowing air into the cells of the gland: these vessels pass on each side of the trachea, one part going into the angle of the right subclavian and jugular, and the other joining the thoracic duct upon the left side.

Like the leg, each arm hath two sets of lymphatic vessels; one immediately under the integuments, belonging to the skin and the cellular membrane, connecting it to the muscles; the other accompanying the large arteries, from the parts deeper seated.

The lymphatic vessels, discovered and delineated, are in general only to be considered as the trunks, since every part of the body has probably vessels of this kind; for wheresoever variolous matter is inserted, the lymphatic vessels carry it into the body, as is shown by its inflaming the conglobate glands through which these vessels pass.

It is by the action of the absorbent system that many noxious materials are introduced into the habit; as the matter of the small pox, the lues venerea, the miasmata of fevers: and it is also by their means that mercury rubbed externally is received into the constitution, and produces similar effects on the interior parts. See For-
dyce's Elements, part 1st. Dr. Hunter's Commentaries. Monro's Description of the Human Lacteal Sac and Duct. Hewson's experimental Inquiries into the Lymphatic System. Sheldon's History of the Absorbent System. Mascagni Historia.

The diseases of the lymphatics are not numerous. They are undoubtedly irritable, and in an inflamed state, at least, acutely sensible; but they never seem to be affected with inflammation from any cause but the acrimony of their contents. In hydrophobia, in lues venerea, and similar complaints, a hard, tender cord may be often traced from the wound previous to the inflammation of the gland. On the other hand, they seem sometimes deficient in irritability; a circumstance on which SCROFULA, vide in verbo, apparently depends.

Amongst these disorders, however, Mr. White properly places the *depôt lacteux sur la cuisse* of Puzos; *ischias a spargonosio* of Sauvages. Most writers have attributed this complaint to a redundancy of milk, and it hence has been often called *œdema lacteum*; by others *phlegmatia dolens*; but it might be more appropriately denominated *ecchymoma lymphatica*. Mr. White describes this disorder more accurately than any other writer, and is the first author who escaped from the trammels of the former doctrine. In about twelve or fifteen days after delivery, he observes, the patient is seized with a great pain in the groin of one side, accompanied with a considerable degree of fever, seldom preceded by a shivering fit and cold rigor. This part soon becomes affected with swelling and tension, which extend to the labia pudendi of the same side only, and down the inside of the thigh, to the ham, the leg, the foot, and the whole limb: the progress of the swelling is so quick, that in a day or two the limb becomes twice the size of the other, and is moved with great difficulty; is hot and exquisitely tender, but without external inflammation. The pain in the groin is generally preceded by a pain in the small of the back, sometimes by a pain at the bottom of the belly, on the same side; and the parts which suffer the most pain are the groin, the ham, and the back part of the leg, about its middle. The pain indeed extends over the whole limb, owing to the sudden distention; but in a day or two it becomes less considerable. It is very hard, smooth, shining, pale, and equable, except where the conglobate glands are situated, which in some cases are knotty and hard, as in the groin, the ham, and about the middle of the leg, at its back part; neither pitting on pressure, nor discharging water when punctured. This disorder generally comes on about the second or third week after delivery; but in one instance it occurred to Mr. White so early as twenty-four hours after delivery, and in another so late as five weeks; but each is uncommon. The first parts that begin to mend, both as to pain and swelling, are the groin, and the affected labium; the thigh next subsides, and lastly the leg. The fever, which is apparently hectic, in some patients declines in two or three weeks, in others it continues six or eight. It sometimes, though rarely, attacks both the extremities. After the disorder has subsided, it is not uncommon for the sound leg to swell towards evening, and become œdematous; but the groin and thigh of that side are not affected; the leg is much softer than the other, and pits when pressed.

It attacks women of all ranks, and of different habits, and is not influenced by the discharge of the lochia, suckling, the nature and duration of the labour, or the mode of delivery, but rather attacks the side on which they lay during labour. The healthy and the diseased; the strong and the weak; the lean and the corpulent; the

sedentary and the active; the young and the middle aged, equally suffer; but it seldom happens after a miscarriage, nor to a woman more than once, though she has afterwards more children. It occurs at all seasons and situations; but neither attacks the arms, nor other parts of the body; never suppurates, nor proves fatal.

The period of the attack, and the elasticity of the swelling, distinguish it from every other disease; and Mr. White supposes it to arise from the child's head pressing the lymphatic vessels, which arise from one of the lower extremities, against the brim of the pelvis, during a labour pain, so as to stop the progress of the lymph, and produce a rupture with a consequent effusion. The extravasation in some habits is re-absorbed readily, in others with difficulty; and by lying out of the course of its circulation, it will press against the uterus and bladder, and occasion forcing pains, and even suppressions of urine. When the orifice made in the ruptured vessel is healed, and the diameter of the tube is contracted or closed, the lymph is retained in the lymphatics, distending the glands of the limb and parts around, and the swelling always begins in that part next to which the obstruction is formed. When the obstruction is in part or wholly removed, or the lymph has found a fresh passage, the part next to it is consequently first relieved. This opinion has been opposed by different authors. Mr. Trye, in his work, published in 1792, considered the disease as owing to an inflammation of the lymphatic gland; Dr. Ferriar, in the third volume of his Medical Histories (1798), thinks its cause an inflammation of the lymphatics of the side affected. Dr. Hall, in an essay on this disease, which he styles *phlegmatia dolens*, published in 1800, supposes it to arise from inflammation and an effusion of coagulable lymph.

We strongly suspect that the nature of the disease is not understood. The fever is apparently idiopathic, and the swelling seems to be a critical deposition, not of pus or of water, but of coagulable lymph. Were Mr. White's opinion correct, it should always appear within a few days, and the fever should be the consequence of obstruction. Were Mr. Trye in the right, the gland should first inflame; and was Dr. Ferriar's system true, pain should be previously felt in the course of the lymphatics. Dr. Hall seems to approach nearer the fact; but the nature of the fever, and the circumstances which influence the deposition, are obscure. Milky depositions, as they have been called, are not uncommon after delivery, particularly in the peritonæum in the peritonitis puerperarum, and other parts; but these are, perhaps, rather depositions of gluten than of milk, or are observable when the milk is checked. In this case the disease is not connected with the suppression of milk; and the only use we can make of the fact is, to show that in such cases the effusion of gluten is not uncommon. If, from fever, such effusion should take place in the legs, we know that, from its density, it cannot be readily absorbed; and it is probable, also, that the lymphatics, by the pressure which usually occasions œdematous swellings in the latter months, may be weakened, so as to be still less equal to the conveyance of the glutinous lymph to the thoracic duct. The circumstances of the delivery, or of the position of the child in utero, may have an effect of determining to one side rather than another.

According to Mr. White, in the first or inflammatory stage, antiphlogistics are necessary, in the degree which the patient's strength will permit. The bowels should be kept lax, the pains alleviated by opiates internally, by anodyne fomentations, and by the warm and vapour bath; blisters on the upper part of the thigh, and emollient injections into the vagina, have been found useful; antimonials, the saline draughts given in the act of effervescence, cool acidulated liquors, and cool air, are supposed useful in relieving fever. In the second stage, when the pain abates, the swelling and tension of the parts lessen, though the quickness of the pulse and some degree of fever remain, the patient may be allowed a little wine and a fuller diet. A dose or two of calomel, of two grains each, given at proper intervals, have seemed useful in this stage. Fifteen grains of myrrh two or three times a-day, in a neutral draught in the act of effervescence, may be taken; or to a saline draught, with myrrh, two grains of the ferrum ammoniacale may be added. The limb may be chafed with warm oil, and bathed at first in water of 82 degrees of Fahrenheit, and afterwards of 76. In the third stage, when no complaint remains, except the swelling of the limb, and perhaps a general relaxation, the bark, with or without steel, will be necessary, dipping the limb in cold water, or embrocating it with spirit of wine and camphor. A circular calico bandage applied to the limb will also assist in the recovery; and if the swelling is confined to the small of the leg, the bandage may be changed for a straight or laced stocking, or for a half boot. Exercise on horseback, and gentle friction, will be of advantage; but walking, or whatever promotes a greater secretion of lymph, will be injurious in every stage of the disease.

Mr. Trye endeavours at first to relieve the fever by evacuating, and then, according to his doctrine, attempts to relax the inflamed vessels by fomentations, leeches, and blisters; to promote absorption by emetics, and in the latter stage by friction with mercurial ointment. Dr. Ferriar applies leeches, with cooling remedies; and Dr. Hull, like Mr. White, treats the complaint at first as inflammatory, and at last as asthenic. In our hands it has appeared an intractable disease, though relieved at last by the efforts of nature. If the patient is truly such, and the practitioner so unprincipled as to continue medicines which he must know will have little effect, he will at last gain the credit of the cure which nature effects. In our hands the fever has yielded to emetics, evacuating, and opiates. The deposition, which soon assumes a chronic form, scarcely yields to any remedies. The Dover's powder, at night, with occasional laxatives, and at last the bark and the squills, have appeared as serviceable as any of the boasted remedies.

See Mauriceau's *Traité des Maladies des Femmes Grosses*, &c. edit. 5, 4to.; Puzos' *Memoire sur les Dépôts Laiteux*, appellés communement Lait Répandu; Levret's *Art d'Accouchement*, ch. iii. sect. 7; Van Swieten's *Commentary on Boerhaave's Aphorism*, 1329; M. Raulin's *Traité des Maladies des Femmes*, en Couché; White's *Inquiry into the Nature and Cause of that Swelling*, in one or both of the lower Extremities, which sometimes happens to lying-in Women: Trye's *Essay on the Swelling of the Extremities of Puerperal Women*; Ferriar's *Medical Histories*, vol. iii.; Hull on the *Phlegmatia Dolens*; and White's *Inquiry*, part 2.

LYMPHATIC GLANDS are those bodies through which the lymphatics pass. Their structure has never been demonstrated; for while some anatomists suppose them to be cellular, others contend that they are merely masses of convoluted vessels. As we know nothing of the change which the lymph undergoes in these glands, we cannot assist demonstration by theoretical induction. We perceive only that nature anxiously delays the passage of the lymph into the blood; as, previous to their entering the gland, the lymphatic vessels are divided into minute branches. This purpose might perhaps be equally answered by convoluted vessels, as by stagnation in cells, since we find the semen elaborated in the lengthened tubes of which the testis consists. Yet the force of the argument, that some secretion takes place in the cells to animalize this new fluid, is not inconsiderable. Since the end is undisputed, we need not contend for the means. Let us, however, only add, that in either case, if the contents are viscid, or the irritability of the vessels preternaturally lessened, stagnation must be the unavoidable consequence.

LYRA, (from *λυρα*, a lyre). The inferior surface of that part of the brain called *fornix*, because its medullary lines resemble the strings of the lyre. See CEREBRUM.

LYRUS, (from *lyra*, a lyre; because its leaves are divided like the strings of a lyre). See ARNICA MONTANA.

LYSIMA'CHIA. YELLOW LOOSE STRIFE, or WILLOW HERB, *anothera*, *lythrum salicaria* Lin. Sp. Pl. 640, (from *Lysimachus*, the supposed discoverer,) is a small plant found about the sides of rivers, said, without much reason, to be astringent. A name of a species of the *mumularia cassida*, and other plants.

LY'SSA, (from *λυω*, to dissolve, à *solutione integritatis sensuum*). The madness of dogs and wolves, or of men who are bit by them. When from dogs, it is called *cynolyssa*.

LY'THRON, (from *λυθρον*, blood). Dust mixed with sweat; sometimes menstrual blood. Hippocrates.

M.

M A C

M. or m. In prescriptions it signifies *misce*, mix; or *manipulus*, a handful. In the late British pharmacopœias it means *mensurâ*, by measure.

MACA'NDON, (Indian,) *cada palava*, a coniferous tree mentioned by Bontius, unnoticed in modern systems, growing in Malabar. Its fruit resembles the pine nut, is rather insipid to the taste, the flowers resembling those of the honeysuckle. The fruit is roasted, and eaten as a remedy for dysenteries, the cholera morbus, and other complaints. Raii Historia.

MACAPA'TLI. See SARSAPARILLA.

MACAXOCOTLI'FERA. The name of a tree in the West Indies, about the size of a plum tree: its fruit is called *macaxocotl*; is red, oblong, of the size of a walnut, yellow within, sweet, and laxative. Two other species are the *atoyaxocotl*, and *cozticaxocotl*, though said to be a species of mirobalans. The other species are *atoyaxocotl chichiltic*; and *chichixocotl*, which signifies *running down with sweat*. A decoction of the bark of these trees cures the itch, and its powder heals ulcers; but the plant does not occur in any botanical system. Raii Historia.

MACEDONI'SIUM SE'MEN. See HIPPOSELINUM.

MA'CER, (from the Hebrew term *masa*). GRECIAN MACER. It is brought from Barbary; its thick yellow bark and dried root are astringent. Its fruit, called *macre*, is said to destroy worms. The plant is not known; but the bark so nearly resembles, in appearance and sensible qualities, the *simarouba*, that they are probably the same. See SIMAROUBA.

MACERA'TIO, (from *macero*, to make soft by water).

MACEBATION, is an infusion or the continued action of water, or any other fluid, on bodies, to lessen their cohesion, or extract their virtue. See DURATUS.

MACERO'NA. See HIPPOSELINUM.

MA'CHA-MO'NA. A sort of calabash in Africa and America; the pulp of which is agreeable, and serves instead of rennet for curdling milk. It does not occur in any systematic author.

MACHÆ'RIA. See PERSICARIA.

MA'CHLIS, (quasi *achlis*, ab a priv. and *κλωα*, *cubo*, quod non cubet). See CERVUS RANGIFER.

MA'CIA. See ANAGALLIS.

MA'CIES, (from *maceo*, to become lean). Diseases in which the body, or particular parts, are wasted. See MARCORES.

M A C

MA'CIS, (το μακισ, *cortex aromaticus*, aromatic bark). MACE, the middle bark, of nutmegs, enveloping their shell, of an oily nature, and of a lively red colour when fresh, growing paler from age. It is dried in the sun upon hurdles, fixed one over another, which gives the appearance of fractured edges, and sprinkled with sea water to prevent its crumbling in carriage. It hath a pleasant aromatic smell, and a warm, pungent, bitterish taste. Its qualities are similar to those of nutmeg; but mace is warmer, more bitter, less unctuous, and sits easier on weak stomachs; yielding, by expression, a more fluid oil, and, in distillation with water, a more subtle volatile one.

The essential oil of mace is moderately pungent, very volatile, of a strong aromatic smell, like the mace itself, thin, limpid, and of a pale yellow colour, with a portion of thicker and darker coloured oil at the bottom. There are three kinds in the shops, though expressed from the nutmeg. The oil of mace is often prescribed as a carminative and antispasmodic. As such it relieves often in colics, and sometimes in nephritic cases. Externally applied, it sometimes relieves vomiting and hiccough. Its internal dose seldom exceeds five or six drops. See NUX MOSEHATA. See Lewis's Materia Medica.

MACROCE'PHALOS, (from μακρος, long, and κεφαλη, the head,) long headed. Some Indians, and many of the Asiatics, have, by pressure, given this form to the heads; and what was at first artificial seems to have been continued by inheritance.

MACROPI'PER (from μακρος, long, and πιπερις, *pepper*). See PIPER LONGUM.

MACRO'PNUS, (from μακρος, long, and πνεω, to breathe). A person who inspires at long intervals.

MA'CUA, (from the Hebrew term *machala infirmiti*). A SPOT, a BLEMISH; a cutaneous efflorescence which changes the colour, sometimes the texture, of the cuticle, but seldom connected with any disorder of the constitution.

MA'CUA LA'TA. The SHINGLES. See ERYSIPELAS.

MA'CULE, or MA'CUA MATRICIS; *navus maternus*; the spots, or marks, supposed to be impressed by the mother's imagination on the fœtus. See NÆVUS.

MA'CULE A'LBÆ. See ALBUGO OCULI.

MA'CULE HEPATICEÆ. HEPATIC SPOTS, or efflorescences proceeding from a dissolution of the blood.

MA'CULE OCULO'RUM. See CATARACTA, or SUFFUSIO.

MA'CULE PESTILENTES; SPOTS, or efflorescences, frequent in malignant disorders.

MA'CULE VOLATICÆ; FUGITIVE SPOTS, such as are often seen in children.

MADARO'SIS, (from μάδος, bald). A loss of the hairs of the eye lids, from an acrimony of the fluids, from eruptions, exanthemata, or inflammation. See DEPLUMATIO.

MADE'LION. See BDELLIUM.

MA'DISIS, (from μάδος, bald). See ACOSMIA.

MA'DOR, (from the Hebrew term *matar*, water). *Ephidrosis*. The sweat which arises during faintness.

MADRE'PORA VULGA'RIS, (from μάδος, smooth, and πωρος, a pore). See CORALLIUM ALBUM RAMOSUM.

MADRO'TES, (from μάδος, bald). See ACOSMIA.

MÆMA'CYLON, (from μαίμαω, to desire; from its beauty). See ARBUTUS.

MAGDALE'NES, MAGDA'LIE, MAGDA'LIDES, (from ματτω, to knead). *Cylindri*; masses of plaster, or of other compositions reduced to a cylindrical form.

MAGELLA'NICA AROMA'TICA A'RBOR. See WINTERANUS CORTEX.

MAGISTE'RIMUM, (from *magister*, a master). The ancient chemists meant by this term a peculiar and secret method of preparing any medicine; but at present it is applied to powders made by solution and precipitation (see BENZOINUM, BISMUTHUM, and CALAMINARIUM LAPIS), to resins, or resinous extracts, or any white powder peculiarly subtle and light. The term generally implies that some of the menstruum remains. At present we have no general idea, or established characteristic, to distinguish magistry from precipitate. Every magistry is some kind of precipitate; but every precipitate is not a magistry.

MAGISTRA'LIS (from the same). See MEDICAMENTA EXTEMPORANEA.

MAGISTRA'NTIA, (from ματ εξοχήν, *magistro*, to rule; so called by way of eminence. See IMPERATORIA.

MA'GMA, (from ματτω, to blend together.) ECPIE'SMA. In a more general sense it is any thick ointment that will not melt with the heat of the body, or a poultice that will not easily spread: more strictly the fæces of any ointment after the thinner parts are strained off: Galen limits the term to the fæces of myrobalans.

MA'GNA ARTE'RIA. The LARGE ARTERY. See AORTA.

MA'GNES. The LOADSTONE. *Calamita, lapis Lydius, antiphyson, lapis Heractius*, from Heraclea, a town in Lydia. The term, however, is singular in many respects. Its origin is uncertain, but its application and influence have been peculiarly extensive: various cities have been styled Magnesia, and the Magnetes constituted no inconsiderable nation in Asia. Many of these cities have been mentioned as the origin of the name; but it is not our object to determine the question. The stone itself was long known before it was employed to direct the course of the navigator; and is usually of a dirty black colour, though in this respect it varies, and is sometimes whitish, from the mixture of silicious particles in such a proportion as to render it fusible. Whe-

ther from its colour, its weaker powers, or any other cause, this was styled the *female* magnet, and magnesia. When the white earth, precipitated from salts similar to the Epsom, was observed, this was supposed to resemble the female magnet, and, of course, called magnesia, with the distinction from its greater whiteness, of *alba*. When another dark metal, similar to the magnet, was discovered, it had the same appellation; but as it did not attract iron, some distinction was necessary, and it was called *magnet*, *manganet*, and *manganesc*. The magnet, our present object, is the *emorphous*, oxidulated iron of Haüy, iv. 13, often found in Europe, in a matrix of magnesian earth, though sometimes in a ferruginous sand, or a sulphurated lime. Its obvious quality of attracting or repelling iron is well known, and in this experiment the north and south poles are attractive, and each repulsive to its own points in other iron or other magnets. Every, the smallest, portion of a magnet has its two poles, not verging to the real poles of the world, but to those of the magnetic meridian, which varies sometimes a little to the east, sometimes to the west. The smaller magnets are more active in proportion than the larger. Magnets, like all iron ores, are astringent, but not used in medicine. They have been recommended by ignorant quacks in ruptures, to attract the intestine upwards, and to destroy the lentor of the blood, by separating the particles of iron in it. Such are the absurdities that deceit will feign and credulity believe. See MAGNETISM.

MA'GNES ARSENICA'LIS, a preparation of arsenic, which we omitted under that article, but which we noticed under CANCER, vol. i. p. 332, col. 2, q. v. Its name was derived from its supposed power of attracting the morbid poison. Geoffroy adds, that it opens, cleanses, and heals scrofulous ulcers, without the assistance of an ointment of any kind. See CANCER.

MA'GNES EPILE'PSIÆ. See CINNABARIS.

MAGNE'SIA, (from *magnesia*, the female loadstone, *magnes*). (See ÆTHEL.) Among the alchymists it means the matter of the philosopher's stone, or sulphur; it sometimes signifies melted tin, with which mercury is incorporated, forming into a brittle white mass; sometimes a mixture of silver and mercury, and a very fusile metal, called *magnesia philosophorum*. But enough of such nonsense.

MAGNE'SIA A'LBA, was a general term which chemists formerly gave to all substances which had the power of attracting any principle from the air. Thus an earth which, exposed to the air, yielded vitriol, was called *magnesia vitriolata*. More modern chemists, supposing that it had attracted the nitrous acid, in its preparation, called it *magnesia nitri*: but, from its colour, it soon obtained its present name, the WHITE MAGNESIA, *albus Romanus pulvis, Comitissæ Palmæ pulvis*. It was introduced as a medicine in the beginning of the eighteenth century, by count di Palma, at Rome, and continued a very lucrative secret. It is a very white, subtle powder, and now known to be a peculiar earth, and the basis of the Epsom salt.

Magnesia was, as we have said, for a long time a lucrative secret, and it scarcely emerged from the language and appearance of a quack medicine, at the time it was first prepared by Mr. Glass of Oxford. Mr. Glass took the form of preparing the medicine from Hoffman.

and was not aware of its nature, or the effect of the addition of the alkali. To Dr. Black we are indebted for the discovery of its being a distinct earth. The Oxford preparation was light and elegant, though unequal; but the imputation of its being adulterated with calcareous earth brought on a dispute between Dr. Glass, the brother of the proprietor, and Mr. Henry. It is now of little consequence where the truth lay; for it is every where prepared with sufficient fidelity. Mr. Henry's process we shall add.

“Dissolve any quantity of sal catharticum amarum in its own weight of water; filter, and add to it, by degrees, a filtered solution of pearl ashes, in an equal quantity of water, stirring them gently, until the mixed liquors have acquired the appearance of a complete coagulum; then cease adding any more of the alkaline lixivium, and immediately throw the mixture into a large vessel of boiling water; keep it boiling for a quarter of an hour, take it out, and put it into a glazed earthen vessel: as soon as the powder hath subsided, and before the water is quite cold, pour it off, and add a fresh quantity of boiling water, till the liquor hath entirely lost its saline taste; next let it be so agitated as to suspend the finer parts of the powder, in which state decant it into other vessels; and having separated the water from the magnesia, by inclination, put it on large chalk stones, until a considerable part of the humidity is absorbed; then wrap it up in sheets of white paper, and dry it before the fire. Pour hot water upon the remaining powder, stir and decant it in its turbid state, and separate the magnesia from the water as before; thus the whole, or the most of it, will be reduced to an equal degree of fineness.

“The larger the quantity of water into which the precipitated powder is cast, the more speedily and perfectly will the vitriolated tartar, which is formed by the alkali uniting with the acid of the sal catharticum, be washed off. The neutral salt should be washed off as quick as possible, otherwise, by allowing the mixture to stand for some time, the powder concretes into minute grains, which, when viewed with a microscope, appear to be assemblages of needles diverging from a point. These concretions cannot be re-dissolved by any washing, however long continued. Dr. Black orders four times the quantity of water to that of the solution to throw the coagulum into, but that is far too little. The water should be pure; distilled is the best; but it should be kept until its empyreuma is gone off. Hard or impure water makes magnesia coarse and disagreeable. The chalk stones on which the magnesia is dried should be exposed to a moderate heat, that the moisture may evaporate quickly. Cleanliness should be particularly attended to through the whole.”

Magnesia, when pure, is white, loose, and light, of the specific gravity of 2.330 nearly. It is perfectly infusible in the focus of the most powerful mirror, except when it contains particles of flint, which, if the alkali is impure, sometimes happens. When the volatile alkali is employed in the process, no flinty particles are found in it. Magnesia melts, however, with borax, and with some of the earths, though more certainly when the earths and alkalis are united. A new manufactory of china, resembling the *seve*, is established at Berlin, in which, instead of the kaolin, a magnesian earth, containing flint and an alkali, is the chief ingre-

dient. Magnesia is nearly insoluble in water, but retains a small portion of this fluid within the interstices of its particles with some obstinacy. When, however, the carbonic acid gas is previously united with the water, the magnesia dissolves readily.

Magnesia contributes to the diffusion and suspension of many resinous substances, and, triturated with camphor, renders this medicine more miscible with water. It is supposed also to increase the solubility of bark in water, if triturated with it previous to infusion or decoction: but it seems to produce some chemical change in the constituent principles of the medicine, as the colour is not only deeper but more red. Whether it is more active as a medicine than the common decoction has not, we believe, been ascertained.

As magnesia contains about seven-twelfth parts of fixed air, it should be calcined before it is administered, at least when flatulence abounds. The air, however, which is expelled by heat, is greedily recovered by exposure to the atmosphere, so that it should be kept in a phial carefully closed. The magnesia contracts no acrimony by calcination.

Like all absorbents, it corrects acidities in the stomach, relieves the heart burn and pain in the stomach, colics and convulsions in children, with every other complaint arising from acidity. It is preferred to other absorbents, on account of its laxative quality, when united with an acid. If mixed with rhubarb, it is said to prevent the rhubarb from leaving a costive habit. If the magnesia does not meet an acid, it is inert, and is sometimes supposed to load the stomach as a heavy cold mass. It has been doubted whether it is proper in bilious or putrid fevers, and much idle disquisition has been employed on this subject; for a prudent practitioner will be led, in such cases, to employ medicines of very different qualities. Magnesia can do no good in either disease. See Hoffman's *Observationes Physicæ Chemicæ*, lib. iv. Obs. ii.; Black's *Observations on the Magnesia Alba*, in the *Essays Philosophical and Literary of Edinburgh*, vol. ii; *London Medical Transactions*, vol. ii.

MAGNE'SIA OPA'LINA; *magnesia rubicunda antimonii*. OPALINE OF RUBY COLOURED MAGNESIA OF ANTIMONY. In making the *hepar antimonii*, decrepitated sal ammoniac is sometimes added to the antimony and nitre, and the result is, the opaline magnesia. It is a weaker emetic than the liver of antimony, and may be given in considerable doses to horses, to produce sweating. Lemery directs it to be made of equal parts of antimony, nitre, and decrepitated sea salt.

MAGNE'SIA VITRIOLA'TA. See CATHARTICUS SAL.

MAGNETISMUS. MAGNETISM, from its effects on the human body, can be scarcely an object of our attention; yet, as folly and fraud have brought it forward in a conspicuous view, it will be necessary to ascertain its real nature, and the advantages which may have certainly been derived from it in medicine. Add to this, that quackery is too fascinating to the human mind to be long without an object, and the exploded artifice of to day may, at a future time, revive in a new form—alter et idem.

Magnetism is strictly the power by which an iron ore attracts or repels a piece of iron, according to the point presented, or attracts only a rude mass. The iron ore,

or magnet, can communicate this property to a piece of soft malleable iron, so as to make it much more powerful than any natural magnet. Iron, also, which has long stood in one position, acquires at either end its power of attraction or repulsion. This property is confined to iron, though cobalt and nickel are suspected of having a small degree of magnetism; and to possess the power of attraction, iron must be in a soft, malleable state. When oxidized in a slight degree, the magnetic power is weakened; when hardened, or in the state of steel, it receives this power in a small proportion. It is equally necessary that its structure (may we be permitted to call it organization?) should be entire; for a magnetic wire, twisted round a stick, does not lose its virtue, while it has not been so much bent as to destroy its elasticity; but, when it can no longer restore its former shape, the magnetism is lost. A smart blow will sometimes destroy, or, in turn, give this power.

Two important errors on this point must be corrected: the one, already noticed, that the magnetic needle, freely suspended, does not lie in the direction of north and south, but a little on the east or west, according to its "variation." This fact is repeated to add, that a needle only becomes spontaneously magnetic by lying in the magnetic meridian. Another error is, that the magnetic influence resides in the earth. In fact, it seems to pass over its surface; for it is much less obvious in caverns than on the earth. The opinion of its cause being one great magnet at the centre of the earth is, of course, without foundation.

It has been usual to suppose the attraction and repulsion of magnetic bodies to be owing to two different antagonizing fluids. This opinion, supported by the authority of *Æpinus*, *Coulomb*, and *Haüy*, should not be rashly rejected. It is, however, seemingly borrowed from the two electricities; and, as we have found that the electrical phenomena with which we are in this work engaged, might be explained on the supposition of a single fluid, so we think the phenomena of magnetism equally compatible with one fluid. Some analogy has been observed between magnetism and electricity; but, if there is any resemblance, magnets are like the electrics per se. Instead of iron being peculiarly attractive of the magnetic fluid, it appears to be the only body which resists it. From this resistance the phenomena apparently arise. Electrics per se equally resist the electrical fluid; but these, if powdered, are changed into conductors. Powdered magnets are still magnetic.

Magnetism differs from electricity in being influenced by very different laws. Magnetism attracts large bodies, electricity small ones; magnetic attraction is constant; electrical variable: the former limited to about two feet, the powers of the latter are unlimited. The magnetic power is also permanent for ages, if not destroyed by an opposite current of a similar nature, as laying two magnets together, with the north poles contiguous, and is not, or very slightly, affected by moisture, water, and oils, nor at all influenced by an electrical atmosphere. A magnet in action may be electrified without disturbing that action, which is also equally active in a vacuum. Heat also diminishes the magnetic power, and entirely destroys it when the iron becomes red; but it is again recovered on cooling.

These observations are sufficient to show that, if

magnetism has no power of its own, little medical effect is to be expected from any fancied analogy to electricity; and, indeed, magnetism has no analogy to any part of our system, except the small quantity of iron in the blood, which is too much diffused to be influenced by it. In fact, magnetism has no effects but in the promises of the artful, and the delusions of the credulous.

Not many years have elapsed since what is called *animal magnetism* was supposed to cure every disease, and to free the mind from the trammels of the body, the load of earth which confines its active excursions, enabling it to pervade, at will, through distant regions, unlimited by time or space. This imposition has had a variety of professors in different countries; and, at one time, seems to have fascinated minds even of a superior order. It affected chiefly the imagination; and the delusion was, in general, confined to the female world, and the weaker classes of mankind. An hysterical paroxysm was produced, and the wanderings of a disturbed imagination were received as the dictates of inspiration. In these wanderings, medical questions were proposed and answered; but all the answers, like those of the ancient oracles, were vague and indecisive. The gesticulations of the professors were directed to particular parts, and supposed to remove the complaints of those organs. While the fancy was inflamed, the effects were thought supernatural. When that cooled, the power lost its influence. The professors have published their secret, which is a strange mixture of absurdity and fanaticism. They are to powerfully excite the attention, to will an end, with views strictly benevolent, moral, and religious. They were not conscious of any means, and this all-powerful influence was to be excited by the volition of the weakest, meanest, sometimes the most infamous, of mankind. The bubble is now burst, and the experience of this age will, for a time, prevent its revival.

MA'GNUM OS; the third and largest bone of the second row in the wrist. See *CARPUS*.

MA'GNUS MO'RBUS. The *EPILEPSY*. *Hippocrates*.

MAGU'DARIS, (from *μαγυδαρις*). See *SILPHIUM*.

MAHMU'DY. See *SCAMONIUM*.

MAHO'GANI. This beautiful wood is procured from the *swietenia mahogani* Lin. Sp. Pl. 548, and the bark resembles, in appearance and qualities, very nearly the Peruvian bark. The trees which produce them are also closely connected by botanical affinities.

MAIA'NTHMUM. See *LILIUM CONVALLIUM*.

MAIDEN-HAIR TREE, brought originally from Japan, by *Thunberg*, was styled the tree of forty crowns, from its usual price; but it is easily propagated by cuttings, and now common. The appellation was derived from its leaves resembling those of the *adiantum*, and *Linnæus* formed a genus, which he styled *ginko*; found only in one of his later mantissa. This plant was the *ginko biloba*. It flowered for the first time in England in 1796, and the president of the Linnæan society referred it to a new genus, calling it *salisburya*, with the trivial name of *adiantifolia* (Linnæan Transactions, iii. 330). It is chiefly cultivated for its beauty and its nuts, which are not produced till the tree is old. They are said by *Kempfer* to be nutrient and corroborant.

MAIL-A'NSCHI. A species of *rhamnus*, growing in Malabar; *Lawsonia spinosa* Lin. Sp. Pl. 498. A

decoction of its root is commended in gout, and of its leaves in jaundice.

MAIL-E'LOU, and MAIL-E'LOU-KA'TOU, are tall evergreen trees growing in Malabar, which are not found in modern systems. A decoction of the bruised leaves and bark is said to be useful in the after pains, and to promote the lochia.

MAJORA'NA, (*quod mense Maio floreat*, because it flowers in May). MARJORAM.

MAJORA'NA CRE'TICA, vel SYRIA'CA. See MARUM SYRIACUM.

MAJORA'NA MAJO'RI FO'LIO, *amaracus, samfuchus*. SWEET MARJORAM. By amaracus the ancients meant sweet marjoram; but by lesser marjoram, the marum. The Egyptians and Syrians call the sweet marjoram by the name of *samfuchus*. It is the *origanum majorana* Lin. Sp. Pl. 825, a low plant, with slender, square branched, woody stalks; and little, oval, somewhat downy, leaves, set in pairs. On the tops grow scaly heads of small whitish labiated flowers, whose upper lip is erect and cloven, the lower divided into three segments. It is sown annually in gardens for culinary and medicinal uses; but the seeds rarely come to perfection in this climate, and are brought from the south of France, where the plant is indigenous.

The leaves and tops have a pleasant smell, a warm aromatic bitterish taste. Infusions in water have a strong smell, but a weak and unpleasant taste: a tincture made with rectified spirit of wine hath more taste than smell. In distillation this plant yields its virtues to water, and affords an essential oil, in the proportion of $\frac{3}{4}$ i. from $\frac{3}{4}$ lxxiv. of the leaves slightly dried, though Beaumè obtained a much smaller proportion. This oil is hot, not so agreeable as the marjoram, and when carefully drawn is of a pale yellow colour; though by long keeping it turns reddish, and if distilled with too great heat is red at the first. The dose is two drops.

The aromatic matter rises almost wholly in distillation, so that an extract possesses very little of the virtues of the plant, which is, like the lavender, a warm, stimulating, nervous medicine. The powdered leaves, the essential oil properly diluted, and the distilled water, are agreeable errhines. In its recent state we are told that it has been successfully applied to scirrhus tumours of the breasts.

MAJORA'NA OLERA'CEA, SYLVE'STRIS. See ORIGANUM ANGLICUM.

MA'LA, (from a resemblance to *malum*, apple). The prominent part of the cheek. (Martinius.) See BUCCÆ.

MA'LA ASSY'RIA. See CITREUM.

MA'LA AURA'NTIA. See AURANTIA HISPALENSIS.

MA'LA AU'REA. See AMORIS POMA, and AURANTIA HISPALIENSIA.

MA'LA COTO'NEA MA'JORA, et MINO'RA. See CYDONIA.

MA'LA I'NSANIA NI'GRA. See MELONGENA.

MA'LA PU'NICA. See GRANATA MALA.

MALABA'RICA HE'RBA. See CORU CANARIEA.

MALABA'RICA PRU'NA. The fruit of the *eugenia jambos* Lin. Sp. Pl. 672. The fruit is subacid and salutary, and a mildly astringent conserve is prepared from the flowers.

MALABA'THRI O'LEUM See CINNAMOMUM.

MALABA'THRI'NUM, (from *malabathrum*). Ointment of malabathrum, compounded of myrrh, spike-nard, malabathrum, and many other aromatic ingredients. See DIONYSOS.

MALABA'THRUM, (from *Malabar*, and *betre*, a leaf). Into this word the Greeks corrupted the Indian appellation *tamalapatrum*. See FOLIUM.

MA'LACA RA'DIX. See SAGITTARIA ALEXIPHARMICA.

MALA'CIA, (from *μαλαχιον*, a ravenous fish). See PICA.

MALACOIDES, (from *μαλαχη*, a mallow, and *ειδος* a form or likeness,) *malva betonicæ folio, malope malacoides* Lin. Sp. Pl. 974, a plant similar in appearance and qualities to the mallow.

MALACO'STEON, (from *μαλακος*, soft, and *οστειον*, a bone). See MORBI SOLIDI SIMPLICIS, and RACHITIS.

MALA'CTICOS, (from *μαλασσω*, to soften). See EMOLLIENTIA.

MALAGMA, (from *μαλασσω* to soften,) *baos*; synonymous with *cataplasma*, from its effects; but formerly malagmas were made of many other ingredients.

MALAGMA A'RABUM. A cataplasm for strumous swellings and tubercles.

MALAGFUE'TTA, or MALAGU'ETA. See PARADISI GRANA.

MALARUM O'SSA. The CHEEK BONES, *zygomatica* and *jugalia ossa*, are the irregular square bones, placed on the outside of the orbits. Their corners are reckoned processes; the longest, viz. the posterior and superior, are called the *superior orbital processes*; the anterior and superior, which end in acute angles, are the *inferior orbital processes*: the anterior and inferior, which are the shortest, are denominated the *maxillary*; the posterior and inferior, *zygomatic*.

MALATS. Neutral salts, composed of alkalis, or earths, and the malic acid. They are little known, and have not been hitherto used in medicine. See MALIC ACID.

MALAVI'SCUS, (from *malva*, the mallow, and *viscus*, glue, from its viscosity). See ALTHÆA.

MALAXA'TIO, (from *μαλασσω*, to soften). The softening of any thing.

MALAZISSA'TUS. *Emasculatus* and *mulieratus*; an appellation of those whose testes have not descended into the scrotum.

MA'LE. See AXILLA.

MALIC ACID. A vegetable acid found chiefly in unripe apples, as well as in plums, gooseberries, elderberries, barberries, and even in the houseleek. It becomes oxalic by the addition of nitric acid, and carbonic acid by distillation. See CHEMISTRY.

MALICO'RIMUM, (from *malum*, an apple, and *corium*, the rind; because it outwardly resembles an apple). See GRANATA MALA.

MALI'GNITAS, (from *malignus*, evil). MALIG-NITY, when applied to fevers, means a high degree of putridity; and its signs are, a slight coldness and shivering, quickly followed by a great loss of strength, a small, quick, and contracted pulse, fainting, if in an erect posture, drowsiness without sleep, or the sleep not refreshing, but followed by a greater decay of strength and delirium. There is little pain, thirst, or

other troublesome symptom, and yet the patient is uneasy, the features contract and sink, the extremities become cold, the pulse intermits, and death soon terminates the scene.

MA' LIS. *Cocytia*. A pungent pain from an animalcule lodged in an ulcerous tumour; or pain from an insect lodged in any part without ulcer or tumour. The insects which produce this pain are various. In Persia it proceeds from the gordius medinensis, or dracunculus persicus; in America by the pulex, and sometimes even by the pediculus.

MALLAM-TO'DDALI. *Celtis orientalis* Lin. Sp. Pl. 1478. The name of a tree in Malabar, whose root, bark, leaves, and fruit, are esteemed specifics in the epilepsy. Raii Historia.

MALLE'AMOTHE, *Pavette, erysipelas curans arbor, pavetta indica* Lin. Sp. Pl. 160; a shrub which grows in Malabar. The leaves boiled in palm oil cure the impetigo; the root powdered and mixed with ginger is said to be diuretic. Raii Historia.

MA' LLEI MU' SCULUS EXTE' RNUS vel **SUPE' RIOR.** See **TENSOR MEMBRANA TYMPANI.**

MA' LLEI MU' SCULUS INTE' RNUS. See **LAXATOR MEMBRANÆ TYMPANI.**

MALLE'OLUS, (from its resemblance to a mallet). The ANKLE. (See **ASTRAGALUS.**) In **BOTANY,** the cuttings of vines, with joints of the old wood at their bottom, resembling a little mallet.

MALLEO' LUS EXTE' RNUS; the talus or ankle bone, or the inferior extremities of the tibia and fibula. See **FIBULA.**

MA' LLEUS. A **MALLET,** and one of the bones in the ears. (See **AURIS.**) This bone hath a large round head, which contracts the whole way from the neck, whence the processus Ravianus arises, and on the outside a short process projects outward, pointing against the membrana tympani. From this part the manubrium or handle is continued down, and its extremity, fixed to the tympani membrana, pulls it inward. When the malleus is in its proper situation, the neck and head are turned upwards and inwards, the handle downwards, its short process upwards and outwards near the upper part of the edge or the tympanum, and the processus Ravianus forwards, reaching to the articular fissure in the os temporis, whence we may distinguish the malleus of one ear from that of the other. The handle of the malleus is tied to the membrana tympani by a fine membranous duplicature. This bone hath three muscles, viz. the *laxator* and *tensor membranae tympani*, and the *musculus externus, auris* Du Vernii.

MALPI'GHIA, (in honour of *Malpighi*). **BARBADOS CHERRY TREE.** *Cerasus Americana, Malpighia punicifolia* Lin. Sp. Pl. 609. The fruit is eaten by the native Americans, but has no medicinal virtue.

MA' LUM. A **DISEASE.** (See **MORBUS.**) In a strict sense it is applied to the unnatural protrusion of the *apple* of the eye, called *procidencia oculi*; consists in an enlargement or protusion of the eye ball, when the eyes exceed the bounds of the eye lids. Its more general meaning is the fruit, *apple*, which in inflammatory and other febrile complaints is allowed as food when roasted. Sliced and infused in boiling water, apples make a pleasant diluting drink. When thoroughly roasted, the soft pulp is applied to the eye in form of a

cataplasm, in cases of ophthalmia, if the eye itself should not be too irritable. Its advantages consist in its very slow communication of heat, in consequence of its texture, so that it continues cold for a long time. See **CALIDUM.**

MA' LUM CI' TREUM. See **CITREUM.**

MA' LUM GRANA' TUM. See **GRANATA MALA.**

MA' LUM MO' RTUUM. A malignant species of lepra or scab, which renders the body livid, with crusty ulcers, void of sanies and of pain.

MA' LUM TE' RRE. See **ARISTOLOCHIA ROTUNDA.**

MA' LUS, (from *μαλον, an apple*). The **APPLE TREE.** The many sorts of apples known in this country are varieties only of one species: at least the crab is our only indigenous apple. Our most valuable species are derived from France, as the names import, the pippin (pⁱⁿ), quarington (charenton), nonpareil, &c. Some valuable varieties are, however, derived from these, under our own hands, which it is unnecessary to enumerate. The apple, when raw, is a cold and flatulent food, not suitable to weak stomachs. The wilding of different countries is the origin of the more improved species, and from it a kind of vinegar is made. Its juice is, however, acerb, and not acid; for it hastens rapidly into fermentation, and if this is carefully checked, it becomes a vinous liquor, resembling old *hock*, which will not by any artifice become vinegar.

MA' LUS SYLVE' STRIS, *agriomela, agrestis, malus acido fructu sylvestris.* The **CRAB TREE,** the wilding, *pyrus malus* of Lin. Sp. Pl. 686, *α.*

MA' LUS AURA' NTIA. See **AURANTIA HISPALIENSIA.**

MA' LUS CYDO' NIA. See **CYDONIA.**

MA' LUS I' NDICA. See **BILIMBI.**

MA' LUS MALABA' RICA. See **CANJRAM.**

MA' LUS ME' DICA, and **PE' RSICA.** The **CITRON, LEMON,** and **PEACH.**

MA' LUS PU' NICA. The **POMEGRANATE.** See **BELAUSTIUM** and **GRANATA MALA.**

MA' LVA, *μαλαχη, (from μαλασσω, to soften).* The **MALLOW,** *malva rotundifolia sylvestris* Lin. Sp. Pl. 969; sufficiently known. Its leaves and flowers are slightly mucilaginous, have no remarkable smell, and are merely emollient. A conserve is made from the flowers; the leaves are used in decoctions for clysters, for emollient fomentations, and in cataplasms. The roots have been employed as a pectoral: they have a soft sweet taste, resembling that of liquorice, but without any remarkable smell. An extract from the tincture is very sweet. The leaves possess powers similar to the althea; and their use is superseded for internal purposes by those of the latter. See Raii Historia; Lewis's *Materia Medica.*

MA' LVA ARBO' REA MARITI' MA; *althea arborea maritima, lavatera arborea* Lin. Sp. Pl. 972. The **MALLOW TREE** agrees in virtues with the common mallows.

MA' LVA BETO' NICE FO' LIO. See **MALACOIDES.**

MA' LVA RO' SEA FO' LIO SUBRO' TUNDO; *malva arborescens, malva hortensis, dendromalache, alcea rosea* Lin. Sp. Pl. 966. **TREE OF GARDEN MALLOW,** and the **HOLLYHOCK.** This plant is chiefly cultivated as ornamental in gardens; and in medical virtues is similar, but inferior, to the common mallow.

MA' LVA VERBENA' CEA; *alcea, alcea vulgaris major, malva alcea* Lin. Sp. Pl. 971. **VERVAIN MALLOW,** is

distinguished from the common mallow by its leaves being deeply cut at the edges. It is similar to, but less mucilaginous than, the other mallows.

MA'LVIA VI'SCUS. See MALAVISCUS and ALTHÆA.

MALVA'SIA, MALMSEY; *marvisium*; a rich generous wine of Spain and the Madeiras, supposed to be the arvisium of the island of Scio.

MALVERN WATER rises in Worcestershire, and it contains lime with a small proportion of magnesia, suspended chiefly by carbonic acid gas. A very small quantity of sea salt is occasionally found in it. The proportion of fluid is very large, and this is one of the purest of our cold mineral waters. It is applied in inflammations of the eyes, and drunk in all complaints of the kidneys and bladder, scrofula and cutaneous diseases.

Dr. Wilson, in a late elaborate work on this water, seems to think that its solid contents, though in a small proportion, may be useful, especially as they are of the kind used in the diseases for which the water is celebrated. He found in a gallon of *Holywell* water above five grains of carbonate of soda, and nearly three of the sulphat of soda. It contained also about a grain and half of common salt, nearly a grain of carbonate of magnesia, and about the same quantity of carbonate of lime. The carbonate of iron scarcely exceeded half a grain. The ingredients of St. Ann's Well were the same, but in a much less proportion. He found the waters laxative; but, at first, they sometimes produced nausea, and occasionally feverish heat.

MAMÆ'RA FŒ'MINA. See PAPAYA FŒMINA.

MAMA'NGA FRU'TEX, an arborescent shrub in Brasil, called by the Portuguese *lavapratas*, but not included in the botanical systems. Its leaves are applied to wounds and ulcers, and the expressed oil of its pods is used in maturing poultices. Raii Historia.

MAME'I. The *mammæa Americana* Lin. Sp. Pl. 731, *mammoe*, *momin*, or TODDY TREE, is a fine tall tree, constantly of a beautiful green colour, somewhat resembling the walnut tree. Its trunk rises to the height of seventy feet, and is terminated by a number of branches which form a vast pyramidal crown. The fruit is twice as large as the fist, and is very agreeable. This tree is found in different parts of the West Indies, but the best are those on the island of Hispaniola. From incisions made in the branches a copious discharge of pellucid liquor, called *momin*, or toddy wine, is produced, which must be drunk sparingly, as it is a powerful diuretic; but it is esteemed a preservative from, and a solvent of, the stone. The fruit is sweet, and of an aromatic flavour; but the two first shells, as well as the pulp which surrounds the kernels, must be removed, since the latter leaves a very permanent bitter in the mouth. It is usually eaten at tables, cut in slices, and macerated in sweet wine. Excellent marmalade is prepared from it by the addition of sugar and spices, which is often brought to Europe as a dry preserve. Brandy distilled from the flowers is highly pleasant, and called the *Creole liqueur*. The gum of the bark kills the chiques which often infest the feet of the Creoles. The Asiatic species is referred, by modern botanists, to the new genus *butonica*, formed chiefly from the *eugenia* of Linnæus, with the *baringtonia*, the *commersonia* of Foster, and some others. A plant which appears to be of this

genus, the *mammæa humilis*, Vahl suspects to be the *rhedea laterifolia* Lin. Sp. Pl. 719. See Raii Historia.

MAMI'RA, is said by Paulus Ægineta to be the root of a plant of a detergent quality. It has been supposed the root of the *doronicum*; but it has not been correctly ascertained.

MAMIRA'AN, is a plant which grows in the water, resembling in its leaf the convolvulus; its taste is hot and bitter, and the seed resembles that of sesamum.

MA'MMÆ, (from *μαμμη*, *mamma*, plural *mammæ*). THE BREASTS. In the breasts we distinguish the mammillæ, or nipples, the areola, the brownish circle around the nipples, and the lactiferous vessels. The breasts are composed of a glandular substance and fat; the glandular part is hard, white, and irregularly mixed with fat, seemingly composed of tubes called *tubi lactiferi*. See LACTIFERI DUCTUS.

Though the breasts are usually spoken of as single glands, they are in reality a congeries of glandular bodies, of a small size, and a somewhat flattened shape. Mr. Cruickshanks has described them as acini; but other authors, with more reason, have supposed these small bodies to be merely convoluted vessels. From these small glands tubes emerge, which enlarge and anastomose freely; but, when approaching the nipple, near the areola, contract and open by distinct apertures. Fifteen of these are often counted on a small nipple, though other anatomists lessen the number. The areola is covered with a skin much more soft and fine than that of the general surface, resembling rather the epheion of the lips and mouth, and interspersed with sebaceous glands, obvious even to the sight, to defend this tender covering from the pressure and the saliva of the child's mouth. The nipple itself is formed of a congeries of these small tubes. The different vessels, either lactiferous or secretory, are minutely divided by fat, and thus give the roundness, the fulness, and firmness of a well proportioned mamma.

The colour of the areola greatly differs even in different women; and, in some, it is so brown, as even in the natural state to give a suspicion of impregnation. (See MEDICINA FORENSIS.) In chlorotic and unhealthy women it is pale; in the Samoeids and negresses black; and in brown persons of a deeper colour. The hue is evidently derived from a fulness of the arteries, though in what manner it is modified we cannot easily say; probably by the colour of the rete mucosum; for all the sexual organs have a brownish tint. In women of the most brilliant and delicate complexions, the colour of the areola resembles that of a rose.

The female mamma sympathizes very pointedly with every part of the genital system, generally with the clitoris, more sensibly and strictly with the ovaria and the uterus. At the approach of the menses the breasts enlarge; at their cessation they wither. After the lochia cease, the milk begins to flow, and this connection is so intimate, that it has been attributed to the anastomosis of the extreme branches of the epigastric and mammary arteries on the abdomen. This is, however, highly improbable; for their union is inconsiderable, and not peculiarly distinct at any particular periods. The sympathy, however, is so striking, that the Hottentots and the Scythians (Herodotus) irritate the vagina to increase the flow of milk from their cows and mares. It is highly probable that the milk is carried to the nipple, and often

discharged from it by the action of its own vessels, and that the child drains the breast, not so much from its own powers, as by exciting the action of the lactiferous tubes. Thus a sensation is felt, when the child approaches, of some internal commotion of the mamma, which females distinguish by the term *warping*, and they are excited so much by the irritation of the vagina, as to render it doubtful if it is always prudent to deprive the hireling nurse of the company of her husband. A sentimental feeling also influences the secretion: thus the milk does not flow so freely on the application of a strange child as of a woman's natural offspring; and exciting the attention, especially if this is accompanied with a little terror, will wholly suspend the discharge.

The connection of the secretion of milk with the general state of the nervous system is also strongly marked. The maternal office of suckling is always attended with a calm serenity of mind, scarcely felt in other situations, and the suppression of the milk, on its first appearance, with irritability, languor, or despondence. The last, indeed, sometimes attends the period of suckling, though the milk continues to flow, from causes that cannot be ascertained. It seems to affect the young and the strong, rather than those of the middle period of life, or of weaker constitutions; the first lyings-in rather than future ones. The apprehensions of death, in those rare and inexplicable cases, are, however, so strong, that nothing can conquer them: the dejection so firmly fixed as to bid defiance to medical aid. In some cases it has continued for some years, but another pregnancy is usually an infallible cure.

Though the final cause of the connection of the uterine with the lactiferous system is obvious, yet, as usual, nature acts by general laws. Thus a false conception is attended with a fulness of the mammæ, and the want of ovaria, as we have seen, has occasioned the breasts to remain in the state of the earliest periods. The irritation of a cancerous tumour in the uterus has, however, no effect of this kind, for it seems of a sedative nature; or perhaps the principium and fons of the irritation must be in the ovary.

It is a circumstance singular and inexplicable that men should have all the organs which produce and convey milk like women. Is it that the sex is determined after the rest of the body is formed, or that, in cases of necessity, men should be able to supply the office of the woman? The first is highly improbable; and though we have one instance of a man affording his motherless offspring this sustenance, the experiment has not been again tried, or not succeeded. Yet, on birth, when all the fluids begin to circulate freely, male children, as well as females, have often milk in the breasts. On the whole, were men subject to a partial plethora like that which takes place in menstruation, and were there an established sympathy between the breasts and genital organs, it is probable that they might become nurses. But neither the plethora nor the sympathy exist; and though we have found tumours in breasts of men, we have never heard of their becoming cancerous. Girls of the best character, by the irritation of a child sucking, have become able to support it. A woman of sixty-eight is recorded in the Philosophical Transactions to have suckled a grand child; and one of eighty, in a Swedish Journal, is said to have performed the same

office. Russel mentions a similar fact respecting a barren sheep, in his treatise *De Tabæ Glandulari*, p. 64.

The number of teats in different animals correspond to the usual number of their young; but it is singular that, however the numbers differ, they are always even. Animals that do not give suck are generally oviparous; but some of the vipers, and some reptiles styled viviparous, are not strictly such; for their young are inclosed in eggs, which are hatched some time previous to the birth. A step between these and animals who are really viviparous may be observed in the didelphis, of which the kangarou is a species. These animals produce their young in an unformed, imperfect state; but they are for a long time concealed, and protected in a second uterus, formed under the belly by a duplicature of the skin, in which the nipples are found. While thus speaking on comparative anatomy, we may add, that the horse was supposed to have no nipples; but Daubenton discovered them under the prepuce.

The arteries and veins are ramifications from the arteriæ and venæ subclaviæ, and from the axillares. The nerves are principally from the costales, which communicate with the nervi sympathetici. The lymphatics pass through the axillary glands, though Meckel suspects that he has traced them into the subclavian veins. See Kolpin de Structura Mammæ, Sabatier Traité d'Anatomie.

MAMMÆA'RA MAS et FŒ'MINA. See PAPA'NAS FŒMINA.

MAMMA'RIÆ ARTE'RIÆ, (from *mamma*, the breast.) THE ARTERIES OF THE BREAST. The *external* are branches from the axillary arteries, and called the superior thoracic. The internal proceed from the anterior and lower side of the subclaviæ, near the middle of the clavicles, and run down for about a finger's breadth, behind the cartilages of the true ribs, an inch distant from the sternum. In their passage they send branches to the breasts, and to several of the adjacent parts; they afterwards go out of the thorax on one side of the appendix ensiformis, and are lost in the recti muscles of the abdomen.

MAMMA'RIÆ VE'NÆ INTE'RNÆ. The right springs from the vena cava, a little below the bifurcation, and runs with its corresponding artery along the internal edge of the sternum. The left springs from the subclavian, or from the axillary vein.

MAMMÆA AMERICANA, Lin. Sp. Pl. 731, the plant which affords the grateful salutary fruit, the *mammè*.

MAMMIFO'RMES, or MAMILLA'RES PROCE'SSUS. See TEMPORUM OSSA.

MA'NACA. The name of a bacciferous shrub in Brasil. The root is powerfully emetic and cathartic, and used on some occasions by the natives (see Raii *Historia*); but the plant is not found in modern systems.

MANATE'A LA'PIS, (from *manati*, the sea cow). *Trichechus manatus* Lin. Syst. Natur. 60. The part of this animal which hath been used in medicine is the os petrosum of the head, which is of various forms, hard, and white, resembling a stone and ivory.

MANCANI'LLA, *hippomane mancinella* Lin. Sp. Pl. 1431. The MANCHINEAL TREE is as large as the oak; the juice of the bark, while fresh, is caustic; the fruit and leaves are equally so, though eaten by goats. The wood is sawed into planks, and brought into England

as ornamental wood. It is of a dusky colour, with brown veins and yellow clouds. It is supposed that the shade of the manchineal tree, as well as the dew beneath it, is injurious; but this is fabulous. Doutour has often rested under its shade without feeling any bad effects; though he suspects, for reasons which he does not assign, that the air is unwholesome, and advises travellers not to seek shelter under it during a whole night. The Indians poison their arrows with its juice; and Valmont de Bomare mentions an experiment with an arrow, which had been dipped in this juice a hundred and forty years before; but a wound inflicted by it on a dog was soon fatal. See Raii Historia.

MA'NCORON, probably sugar, since it is a sweet substance found in cane. Oribasius.

MANCURA'NA. See ORIGANUM.

MA'NDARU, *assitra*, *baubinia variegata* Lin. Sp. Pl. 535, the pod bearing Malabar tree with bifid leaves. The flowers purge; and the roots, if chewed, relieve pains in the teeth. All the species of *Baubinia* appear to possess similar qualities.

MANDI'BULA, (from *mando*, to chew). A JAW. See MAXILLA.

MANDI'BA, MANDI'BABURA, MANDI-BU'MANA, MANDI'PEBA, MANDIO'CA. See CASSADA.

MANDRA'GORA, (from the German *man dragen*, bearing or resembling men). *Canina malus*; *dudaim*; the MALE MANDRAKE, *atropa mandragora* Lin. Sp. Pl. 259, hath monopetalous, multifid, bell shaped flowers; its fruit is soft, globular, and contains seeds, which are generally kidney shaped. It is common in Spain, Italy, and other hot countries: is anodyne, narcotic, and cathartic; but only used internally as a discutient.

The roots of the marsh mallow, of the arundo, and of bryony, are made to resemble the male mandrake roots.

MANDRAGORI'TES, (from *μανδραγορα*, *mandrake*). The MANDRAKE WINE is made by putting half a pound of the bark of the mandrake to nine gallons of wine. After standing three months the process is complete.

MANDUCATIO, (from *manduco*, to chew). See MASTICATIO.

MANDUCATO'RES MUSCULI, (from the same). See MASSETER MUSCULUS.

MA'NGA. (Indian.) *Mangas*, *amba*, *ambalam*, *mao*, *conchifolia*, the MANGO TREE, *mangifera Indica* Lin. Sp. Pl. 290, is a native of the East Indies. The fruit is larger than a goose's egg, flattened, shaped like a kidney, and of a gold yellow colour. It is pickled unripe in the acid milk of the cocoa nut, the kernel filled with garlic, and, in that state, sent to Europe. See Raii Hist.

MA'NGA. See ABALAM.

MANGANESE. *Magnesium*, *magnesia nigra*, and *siderea*, *manganese oxyde* Haüy iv. 243, is of a black brown colour, with occasionally a little of the metallic splendour, of a specific gravity from 3.70 to 4.75. Some varieties which stain the fingers are much lighter. It is divisible in rhomboidal prisms of about 100° and 80°, and colours borax of a violet hue when exposed to the blow pipe. It was long supposed to be an ore of iron, and though shown in 1770 by Kaim to contain a peculiar metal, it was only completely reduced by Gahn about the year 1774. Manganese attracts oxygen more rapidly than any other body, except phosphorus and the black oxide; that most commonly employed con-

tains sixty parts of the metal and forty of oxygen. In this variety the oxygen seems in excess, and the excess only is yielded in decomposition; for the white manganese retains its oxygen with great obstinacy.

It is needless to enlarge on the preparation of manganese, as its chief use is in preparing the oxygenated acids and salts. M. Alyon has recommended an ointment composed of the black oxide of manganese with axunge, in the proportion of one drachm to an ounce, which he recommends in a variety of external diseases, where the oxygen is apparently deficient, but whose boasted merits experience in this country has not supported. In the preparation of oxygen for respiration, manganese is chiefly used, and it is the principal ingredient in Guyton's box to secure from contagion. Those, however, who prepare oxygen gas should recollect the observation of M. Seguin, that some manganese at first yields a portion of azotic gas.

MANGARA'TIA. See ZINGIBER.

MA'NGLE. See GUAPARAIBA.

MA'NGOSTAN. *Garcinia mangostana* Lin. Sp. Pl. 635. A tree which has been transplanted from the Molucca islands to Java, and at Batavia is admired as an ornament in gardens. It resembles the citron tree, has a straight trunk, an equal and regular head, and rises from eighteen to twenty feet in height. The mangostan, in the works of modern naturalists, is of the natural order *guttifera*, as some of the species afford a gummy resin, resembling, in appearance and power, the *gutta gamba*. The fruit is equally pleasing to the smell and taste. The odour resembles that of the strawberry: the flavour is said to unite the sweetness of the cherry, the orange, and the grape. The mangostans are wholesome, refreshing, and never produce any inconvenience. Dr. Solander, who was at the point of death from a putrid fever at Batavia, found them so refreshing, that he attributed his recovery to them. The fruit itself is laxative, the bark styptic and astringent. The decoction of the bark is given in dysenteries, and employed as a gargle in aphthæ. The Chinese employ the bark in their black dye. The only other species of the system of nature affords a much more acid and less grateful fruit; and, indeed, it seems a variety only. To this genus Gærtner has referred the gambogia gutta of Linnæus; but on this subject we have already spoken; and Lamarck has added two other species.

MA'NIA, (from *μανιαμαι*, to rage,) *dclirium maniacum*, *paraphrosyne*; *phrenitis apyreta*, *heraclæus*, MADNESS. (See also MELANCHOLIA.) This disease receives different appellations, according to its violence, its causes, and attending circumstances. Melancholy is the primary disorder, and madness is supposed, though inaccurately, to be the higher degree.

Madness, in all its species, is a chronic disorder, and has been defined, "The perception of objects not existing, or at least not corresponding to the senses," and is consequently a preternatural state of sensation. Dr. Cullen places it in the class *neuroses*, and order *vesaniæ*, defining it an universal insanity. This definition is, however, very defective, since the chief term is the object of the definition. That of Sauvages is still more exceptionable, as he confines madness to errors of judgment with fury. Those of Linnæus, Vogel, and Sagar, either define mania by insanity, or confine it to fury and boldness. Dr. Battie, who styles it false perception, is equally imperfect. It may, perhaps, be more

correctly defined an irregular exertion of the mental powers, particularly those of perception and judgment, without fever, often with great violence. Dr. Cullen distinguishes three species; the *mania mentalis*, when wholly from the affections of the mind; *mania corporæ*, or *inanitorum*, when evidently from a fault in the body; *mania obscura*; when not preceded by any evident mental affection or disorder of the body.

These species are, however, incorrect; but a mere nosological disquisition would not have detained us, had not this view of the subject led to erroneous ideas of the disease. Perhaps there is no disorder purely mental. When affections of the mind produce corporeal complaints, they first act by injuring the functions of the body; when the mind also is diseased, bodily changes first appear; and, in the case before us, the most purely mental mania are found to arise from topical affections of the brain. (See MENS and MENTALES.) There is not even a sufficient foundation for distinguishing those species which arise from atonic gout, repelled eruptions, syphilis, &c.; for, though originating from bodily causes, they continue like the apparently mental diseases. In short, there is no foundation for the subdivision of species in this complaint; since, like many other reputed genera, it is only itself a species.

The union of mania with melancholy is, we have said, equally inaccurate; for the melancholic mania is a variety only. We shall find melancholy distinguished as a peculiar temperament, marked by languor and inactivity in all the functions; and, while it occasionally rises to insanity, even in its last stage, it is clearly distinguishable from other varieties of mania. The phlegmatic, the sanguine, the bilious, as well as the melancholic temperament, are subject to insanity.

Some authors have unnecessarily varied the species from the circumstances or causes of the disease, almost realizing the axiom of the porch, that all fools are mad; but these are only varieties, and scarcely admit of any difference in the practice.

Dr. Battie, we have said, considers madness to consist in false perception; but this is a partial view; for the perceptions are often correct, but the reasoning or the judgment are defective; yet the perception is more frequently in fault than the reasoning. The mind is all alive, but its exertions are irregular; indeed the mental excitement is so great, that mad persons are often not subject to the effects of cold, nor generally susceptible of the infection of fever. On the contrary, other diseases are cured by madness coming on. We remember to have seen a most inveterate asthma immediately relieved by a maniacal paroxysm, and the asthma returned when the madness lessened. It has been said, on the contrary, that madness is itself removed by the access of an intermittent; but we hesitate in admitting observations made at a time when intermittents were thought highly salutary.

M. Pinel, in a late work on insanity, has hazarded a more singular opinion, viz. that the violence of maniacal paroxysms may be only efforts of nature to relieve some latent disease. Though this idea may be, in some measure, countenanced by the facts mentioned respecting asthma, yet its general absurdity is too striking to require our employing a moment in its refutation. The species of mania, according to this author, are less ex-

ceptionable. These are melancholia, or delirium, on one subject exclusively; mania without or with delirium; dementia, or the abolition of the thinking faculty; and idiotism, or the obliteration of the intellectual faculties or affections. The second species only requires a remark. It is defined "a perversion of the active faculties, marked by abstract and sanguinary fury, with a blind propensity to acts of violence, without any sensible change in the intellectual functions." There is, however, some doubt, whether this is properly a species. The instances are, in part, those of violent passions, in support of the axiom *ira furor brevis*; and, in part, of paroxysms truly delirious. Periodical mania, according to M. Pinel, is only a form of madness, and not a distinct species, classed as a variety of the third.

The false perception, or false reasoning, which distinguishes mania, sometimes pervades every subject, but very frequently one only. Of the latter Don Quixotte affords an admirable specimen, drawn in a style truly interesting and correct, and supported with the precision which the most minute medical observation could not improve. In Le Sage and Smollet we have pictures of the same kind delineated with equal skill, though not equally extended. In general, the subjects on which this kind of insanity is conspicuous, are those less familiar to the patient's general habits of life, and on which he is imperfectly informed. The tradesman is bewildered in his calculations for paying the national debt; and the debauchee in investigating the mysterious ways of Providence, or reconciling the sublime truths of revelation with the shallow views allotted to human reason. As religion is of all subjects the most interesting, and least within the powers of the human mind, it is the most common cause of insanity, and of the most obstinate cases of the disease.

Insanity seldom attacks at once: its approaches are gradual; and, as suspicion and cunning are the most striking mental symptoms, these are often conspicuous in the earliest stages. In delineating the symptoms, we must distinguish between the idiotic insanity, the melancholic, and the sanguine; for these are the most striking varieties. We mean not at present to dispute the propriety of distinguishing complete idiotism as a species, but merely to mark that languid state peculiar to leucophlegmatic habits, and approaching with slow, undistinguishable steps.

The *idiotic insanity* commences with silence and reserve; with muttering, inattention to the person who speaks; and a want of recollection of what has lately passed. The muttering becomes more distinct; and it then appears that some images are presented to the mind different from the objects before the patient. In fact, if "*false perception*" does not take place, objects do not make their usual impression, or the mind, less impressed with the objects around than with its own ideas, suffers the latter only to have any influence. In this state the sleep is usually disturbed, though sometimes sound and uninterrupted; but, when sound, the patient is not refreshed, nor is the mind more steady when awakened. In general, the head appears loaded, and the eyes red; though, in some cases, each symptom is wanting, but the bowels are always slow in their action, and stools are unfrequent; the patient is insensible to the calls of hunger and thirst, to the impressions of cold, but not indifferent to worldly objects. On the contrary, distrust

and suspicion predominate; and the greatest cunning is exercised to obviate the effects of what the patient supposes most detrimental to his interest. The pulse is often little affected, and the urine copious and pale.

Even in this situation opposition will excite to violence, and strength, apparently incompatible with the general weakness will be exerted, to counteract what the patient may dislike. In this case the eyes become quick and fiery, the countenance is animated, while the extremities are cold, the hands tremble, and every function, except what is roused to opposition, appears peculiarly weak.

The *melancholic* madness does not greatly differ; but the patient, when roused to answer, appears to have lost none of his mental faculties. Often, while his fancies prevail, he will reason with acuteness in their support, and his precautions to guard against injury, when he fancies himself a brittle vessel, are ingenious and well conducted. In these circumstances the pulse is languid, the bowels peculiarly torpid, the urine limpid, the sleep often heavy, but without relief, or, when it occurs, the patient is insensible of it, and denies, with violence, having slept. The mind, in this kind of madness, rests on one idea, with unusual pertinacity, and the violence, on contradiction, is peculiarly vehement. The distinction between these two varieties does not seem to consist so much in the temperament, as in the wandering in the former, and the permanent ruling idea in the latter. To which we may add, that the first is the disease of a weak, and the latter of a strong mind. Aretæus describes the melancholic mania with singular precision. "Those who are affected with melancholy are sad, dejected, and dull, without apparent cause. They tremble for fear, are destitute of courage, affected with watchings, and fond of solitude. They are prone to anger, changeable in their tempers, and ask a reason for the most trifling and inconsiderable occurrences. They are at some seasons so covetous that they will not part with any thing, but soon become silly and prodigal. They are generally costive, sometimes discharge no fæces at all, at other times their excrements are dry, round, and covered with a black and bilious humour: they discharge a small quantity of urine, which is acrid and bilious. A large quantity of flatulencies are discharged from their mouths; and sometimes they vomit a certain acrid humour with the bile. Their countenances become pale, their pulse is slow. They are lazy and weak, but discover a præternatural voracity in eating their aliments. When the disorder advances to madness, the patient, when provoked to anger, becomes raging mad. Some wander far from home; some cry out in a hideous manner; some shun the sight of men, betake themselves to solitude, and only converse with themselves; others tear and mangle their bodies. In the highest degree of this disorder they perceive red images before their eyes, so that they in a manner think themselves struck by lightning. They are immoderately inclined to vengery, so that they caress publicly, without either dread or shame. But when the disease is in its decline, they become stupid, calm, and mournful; and coming to the knowledge of their misfortune, they are dejected on account of their calamitous and miserable situation."

The *sanguine* mania greatly differs. It is at first

marked by irregularity of spirits, sometimes highly elevated, and proportionally depressed; in either case without sufficient reason. This kind of insanity is often the effect of sudden and excessive joy; and madness was more commonly the effect of success in the South Sea year, than of disappointment. An early symptom is a loud and rapid elocution when speaking on common subjects, a feeling of peculiar high health, and boasting declarations of health and spirits. The sleep is very disturbed, and the watchfulness often unremitting. The subjects are as various as the fancy; each is suddenly indulged, and as quickly superseded by another. The persons most loved, before, are now detested, and strangers, or the most indifferent people, are sought after with anxiety. The eye appears wild and red, quickly glancing at every object; the face flushed, a tingling in the ears is perceived, and suspicion is alive in apprehension of intended injury; for there is always an enemy in the rear, which is often one of the nearest relations. It is not an uncommon fancy to suppose those around them mad, and their greatest amusement to contrive stratagems in order to secure and confine them. When any object is in view, disappointment does not distress them. The object still remains, and it is to be accomplished on another occasion. The prospect is always cheerful, and success constantly at hand. The pulse, in this case, is often natural, but frequently quick: the tongue is always dry, the skin without the softness of health, the urine generally high coloured.

Though we may declaim, "what a wonderful piece of work is man!" yet, when we view him in this state, where his boasted reason, instead of assisting, misleads him; when we see him exposed to elemental war, insensible of cold, of the comforts of cleanliness, of the dictates of religion, of even common decency; when we hear him uttering blasphemous execrations, employing the grossest and most obscene language, language abhorred in the lucid moments, when recollection often adds to the horrors of his situation, we may truly exclaim, "Alas, poor humanity!"

We have sketched only the outline of the picture, the discriminating features of the object. To fill it would require a volume; for, so various, so singular, and so numerous are the eccentricities, when judgment no longer guides, that it is impossible to detail them. In the general conduct of the human mind, when the balance of judgment or of authority is wanting, the wildest absurdities are equally the consequence; and, within the pale of reason, we observe conduct which almost realizes the stoical maxim already alluded to.

Mania often remits, and at times recurs periodically. It has been found to return at the full and new moon, or, at least, to be exasperated at those seasons. Mania is, however, always considered as varied by lucid intervals, and in a certain degree is so; but this seems rather a salutary fiction of the law (see *MEDICINA FORENSIS*) than the result of medical observation. The violence of the maniacal patient, indeed, often remits, and is exasperated.

We know no peculiar constitution predisposed to mania except the melancholic. A tendency to the sanguine variety of this disease is shown by a flighty, irregular, and variable conduct, rising to exuberant spirits from the lowest depression, and again sinking,

from the former, into grief and despondency; to the melancholic, by a fixed attention to one object, from deep thought, never alternating with cheerfulness, and seldom varying its views. The idiotic frenzy appears from a generally variable, trifling temper, with little reflection, and less judgment. This kind is, however, unfrequent; nor would we condemn every trifling male or female because they are such. Our receptacles must, in that case, be particularly numerous and roomy.

A very frequent corporeal remote cause is gout; either not brought out, repelled, or not properly supported. Repelled eruptions, or a check of any usual discharge, are by no means uncommon causes. Mania sometimes attends each succeeding pregnancy, and, in turn, the melancholia lactantium, as we have said, is cured by pregnancy. An asthmatic fit has, on its recession, been succeeded by madness; and a maniacal paroxysm has, in turn, yielded to a spasmodic asthma. The mind is intimately connected, as we have seen, with the genital system; and the denial of those enjoyments which nature claims, is a frequent cause, though an unsuspected one, of mania; in men chiefly of the melancholic, in women of the sanguine, kind.

Among the mental, remote, causes, or rather the causes originating from mind, we may mention disappointment, grief, hope long delayed, or destroyed by unexpected reverses, wild extravagant joy from unexpected prosperity. These produce the corporeal changes, which often induce madness.

Mania is undoubtedly constitutional, and propagated from parents to children, sometimes leaving one whole generation unaffected, and appearing again in the next. It is apparently propagated with the form, the features, and complexion, like scrofula; nor is this the only argument in favour of its being a truly corporeal, organic affection.

The most striking and constant corporeal change in mania, is fulness of the vessels of the brain; and, though this is less apparent in the wandering, idiotic mania, it very frequently exists. In that wandering, which arises from weakness and inanition, no such fulness occurs; but this cannot be called mania, and in those temporary derangements of intellect, which arise from deleterious substances taken into the stomach, it is equally absent. These, also, our definition excludes. Yet, when even these are separated from our view, it would be rash to assert that a distention of the vessels of the brain is constantly found in mania.

Dissection certainly discovers such distentions in a great variety of instances; but we are informed also, that sometimes a preternatural dryness and hardness of the medullary part, sometimes an undue softness, is found in the contents of the cranium. More frequently tumours, sometimes abscesses at the base of the cerebrum, sometimes exostoses from the cranium, are discovered, though the last are more commonly the cause of convulsive paroxysms. The leading symptoms of mania are inconsistency and a disturbance of the usual associations, and these necessarily arise from a want of communication between its different parts, or an irregular distribution of the nervous power. The want of communication may arise from mechanical obstruction, from a destruction of the organization of some part of the brain, perhaps from a change in the qualities of what we have styled the nervous fluid. The irregular

distribution may be owing to increased excitement of one portion of the medullary substance, or to the diminished power of another. Dissections countenance all these opinions; but unfortunately we have few cases in which the symptoms are connected with the appearances on dissection, so as to explain the influence of the organic changes in different circumstances. In general, we know that the medullary substance, in cases of idiotic insanity, is usually soft and watery; in melancholic cases, hard and dry; while in the wild, furious mania, some active irritating power is generally discoverable. Abscesses at the basis of the brain are usually attended with a low muttering delirium.

The form of the cranium has been supposed a cause of mania, and it has engaged much of the attention of Pinel. He finds, however, no very striking connection between its form and maniacal affections, except in idiots, where the upper part of the head is shortened, the sides flattened, and the whole cranium elongated. In general, the most distinguishing marks of the skulls of maniacs are a flatness of the temporal bones, and a retracted occiput. A thickness of the skull is sometimes found on the dissection of maniacs; but this is by no means a peculiar or a constant attendant. Pinel seems not to have observed the softness or dryness of the medullary portion of the brain, mentioned by other authors. In his dissections, the fulness of the vessels appears to have chiefly attracted his notice.

The prognostic in this disease is usually unfavourable, except when it arises from repelled eruptions, imperfect gout, or the stoppage of the discharge of a fistula in ano. When it arises from a constitutional organization, or without any distinct cause, it is seldom cured. The idiotic mania is more frequently intractable than the violent, and the disease from religious impressions very rarely yields to any plan of relief. When from violent and continued grief, from disappointment, particularly disappointed love, the disease is particularly obstinate. If sleep does not relieve; if emetics and purgatives fail of their effect; if convulsions come on, or considerable debility is observed; the complaint will be obstinate, or death soon ensue.

The diagnosis is not difficult. The absence of fever clearly distinguishes mania from any disease with which it can be confounded.

The cure of mania is simple, or at least art, often disappointed, has ceased to interfere with activity. The wandering delirium from inanition, the singular fancies from swallowing deleterious substances, vanish with increasing strength, the evacuation of the cause, or its continued impression which soon becomes habitual. The varieties of mania which we have mentioned may appear each to require a different plan; but the conduct of receptacles for lunatics is often empirical, and, even when under the direction of a physician, seldom conducted with scientific views. We may not improve, but shall endeavour to connect, the scattered limbs found in different authors.

In each variety of mania we always find a considerable determination to the brain; and, even when the disease arises from some organic affection, which seems to interrupt the free communication between its different parts, this interruption appears to act as a local obstacle, which excites the action of the vessels around. On this view whatever is rational in the

conduct of the cure seems to depend; and the remedies we shall mention in the order of their importance.

Emetics have been generally and principally employed, and the source of their advantages are sufficiently explained in that article. Without any other assistance, they have often removed a maniacal paroxysm; and, when repeated at regular and not very distant intervals, they are often highly useful.

In general, common emetics from the torpor of the stomach will not produce the evacuation, and antimonials are required. To these the vitriolated zinc, with mustard whey, must be often added; and the tobacco, the juice of the asarabacca, or groundsel, are often required. The objection made to emetics by those who have never used them, that they determine too powerfully to the head, we have already considered. See **EMETICA**.

Cathartics are, however, chiefly depended on, for reasons which will be sufficiently obvious, and these are particularly useful in melancholic mania. In the sanguine variety the saline are preferable, but they are scarcely sufficiently active in the melancholic; and when the disease arises from the want of the necessary evacuations from the lower belly, those purgatives which chiefly excite the action of the colon and rectum are most useful. The ancients used hellebore, but they diminished its activity by their mode of preparing it; and we do not find that it possessed peculiar powers, though if the plant they used be, as we have reason to suspect, a species of adonis, it probably combined the qualities of an anodyne with those of a cathartic.

What has been remarked respecting the large proportion of the vital fluid contained in the extreme vessels will sufficiently explain the effects of **DIAPHORETICS**. Yet we find no striking instances of their utility; and the impatience of maniacs, which leads them to throw off their clothing, seems to counteract this discharge. In fact, however, the heat is above what has been styled the sweating point, and the diaphoresis is best secured by moderating its excess. The only remedy of this kind which seems to have been peculiarly useful is vinegar. It was given with camphor by Dr. Locher of Vienna, but was found equally or more effectual without the camphor. Mr. Pargeter has recommended a camphorated vinegar in this country, but we have not found it peculiarly beneficial. Warm bathing, which is a remedy of this kind, has been highly commended, and is certainly useful when the heat is moderate, not exceeding 96° or 98°. We have not mentioned **BLEEDING**, because it is not peculiarly advantageous; but when the mania rises to violent delirium it is necessary, and the blood must be drawn with a decisive boldness, so as to excite deliquium. Bleeding from the jugular veins, and topical bleeding with leeches, or the cupping glass, if the quantity drawn is considerable, will be highly useful; but this, too, is confined to the violent state, when the mania becomes phrenetic.

Blisters, with similar views, have been applied; but they are not favourite remedies. Is it that their discharge is more adapted to relieve active inflammation, and less suited to the chronic fulness; or that danger is supposed to arise from their irritation, which has led practitioners to doubt of their utility? We believe, indeed, that they are not particularly useful, and that the deeper, purulent discharge from a seton is

more advantageous. A blister, to be really beneficial, must be applied to the vertex.

Dr. Mead speaks of the utility of *diuretics*, but we know not that modern experience supports their credit, for we have not had sufficient confidence in this class of remedies to employ them. The diuretic preferred was the alkaline salts, and the opinion of obstruction, from lentor, was then so common, that we can easily guess the source of the recommendation, and of the good effects attributed to it.

Sedatives are most obviously indicated, and the whole tribe has been employed with varied success. Each medicine has had its sanguine advocates, and each has, at different times, succeeded. The refrigerants are chiefly trusted, and the neutral salts, combining this power with their purgative effects, are very commonly administered. Nitre is less often employed; but cold, in all its forms, is found peculiarly salutary. The clay cap has yielded to cold affusion of water, or fomentations of the coldest water and vinegar; and madmen have been kept under water by violence till nearly suffocated. The maniac, who has escaped from confinement, and remained exposed to the greatest cold, has returned in his senses; and those who have been with difficulty saved from drowning have escaped from the danger and the disease.

The sedative antispasmodics are the fœtids, musk, and camphor. The former are comparatively weak; musk is more powerful, but rarely genuine, and always expensive. Camphor is more active than either, and we have found it, in large doses, a valuable medicine. Less than a scruple at each dose would be, perhaps, useless; and few can bear more than half a drachm. The warm bath seems to have been sometimes successful in this view.

The narcotics have been employed in all their variety, particularly by the German and English physicians. Storck used the stramonium; Colin the cicuta and aconite. The ancient hellebore, we have said, was probably a species of adonis; Willis gave the extracts of cicuta and henbane; Fothergill, of Bath, the henbane only. Lately, the digitalis has been given, in this country, to a considerable extent. These narcotics have been often useful, and have as often failed, for the disease is generally incurable. Perhaps the digitalis promises most favourably, and the hyosciamus and stramonium appear to be the next in rank.

These medicines often act as hypnotics; but the chief of this class, opium, has been commended, and rejected rather from theoretical prejudices than observation. Where opium usually agrees, it is a medicine of considerable importance in mania; but it should not be given till the stomach and bowels have been freely emptied, till the vessels of the head have been, in some measure, depleted by active topical bleeding, by blisters, or a seton. In these circumstances, with a large dose of camphor, it is often highly useful, though like other medicines, in an intractable disease, it must occasionally fail. Borax, in a large dose, was used by Dr. Monro to procure sleep.

We have observed, that there are cases where the interruption of the balance between the different parts of the brain are owing to diminished activity of one portion of this organ. But these, we have said, are few and indistinct. Cases of this kind are chiefly the

transient wanderings after being awakened from sleep, or the want of recollection after long fevers, or other causes of weakness. Should mania occur, in such situations, a nutritive diet, tonics, with perfect tranquillity, are the best remedies.

The mental regimen, or, as Pinel calls it, the moral treatment, is confessedly of the greatest importance; and the medical exertions in the most celebrated receptacles are generally slight, but strictly supported. Tales have been told, that the patients in some of these houses are not suffered to sleep; that the severities have been unusually cruel; that, in the language of Julian, the *populous* hair has been recruited, designedly, with new colonies; and that derivation to the skin has been kept by the infection of a cuticular disease. Of the truth of these stories we cannot judge; but it is, we believe, a fact, that when the mind is restored it is often at the expense of the constitution; for patients have come to us, from some asyls, with their general health and strength completely broken. It is not for us to say that the regimen and severities were unnecessary, or even to hint that the mind is recovered at too great an expense, by the diminution of the vital power. Yet, when the maniacal fancies are harmless; when the disease seldom rises to violence, and the patient is usually manageable, if relief by common treatment is improbable, we cannot say that such severities are advisable. The violent and continued excitement is, however, alone sufficient to account for the subsequent debility.

As we have declared that we are not of the initiated, we might decline all farther remarks on the mental regimen; but we must add what the experience of others, aided by our own, has taught us, that the maniac is always a coward. With the strength of twenty men he will crouch to an infant, if that infant assumes a haughty and firm tone. A look of confidence will soon have the same effect; and the dread of severities which he has felt, or has reason to expect, will render that look irresistible. With this cowardice, the maniac is cunning, and it is necessary to guard with the utmost care against his artifices; but the great advantage is derived from the prompt and ready obedience which the look ensures. This checks every idle fancy, and stands in the place of the reason and judgment which were once his own. The mind, in this way regulated, assumes spontaneously its usual trains, and by steadily persevering in this tract, reason often returns. Thus, in the case alluded to in common life, when the conduct is no longer regulated by judgment or authority, the wildest eccentricities are the consequence. Should a *justus et propositi tenax* interfere, the whole order is restored with its wonted regularity. If severities should be required, they must be truly such, to prevent the necessity of their repetition; and the proper waistcoat, made with sleeves to fasten by running strings beyond the fingers, and by these to confine the arms across the body, is often necessary to prevent the maniac from injuring himself or others.

The moral treatment, according to Pinel, is of the greatest importance. It seems to consist in yielding to the more harmless fancies, and firmly correcting the more dangerous ones; at the same time endeavouring to bring back the usual and healthy train of ideas. What numerous cases of insanity has the French revolution produced!

This command ensures also the punctual obedience in taking the few remedies prescribed. These are, we apprehend, chiefly laxatives of the saline kind, nitre, camphor, and opium, with drains from the head by means of a perpetual blister or a seton, remedies chiefly, if not exclusively, useful in lessening the impetus of the fluids to the head, certainly the principal object in the treatment of the disease.

The diet should be regulated with the same view, and should be mild, light, and not highly nourishing. The drink chiefly water. Exercise, when the case will admit of the mind being amused, is highly proper; and cheerful company, who possess steadiness sufficient to repress the ruling fancies, and discretion to lead to proper subjects, without continuing the conversation so as to fatigue, is often highly salutary. Music, too, which steals the mind from its favourite train of thought, and leads on the attention by its peculiarly fascinating powers, to those who are fond of it, contributes greatly to the relief.

See Aretæus, Alex. Trallian, Celsus, Sennertus, Hoffman, Sydenham, Boerhaave, Beattie, and Arnold on Madness; Muzzel on Melancholy; Cullen's First Lines, vol. iv. p. 144; Pinel on Insanity.

MANIGUE'TTA. See PARADISI GRANA.

MA'NIHOT. See CASSADA.

MANI'BA. See CASSADA.

MANIO'DES, (from *mania*, madness). MANIACAL. See FERINA.

MA'NIPEY. See JACARANDA ALBA.

MANIPU'ERA. See CASSADA.

MANI'PULUS, (*quòd manum impleat*). A HANDFUL, *desme*, *dragma*, *fasciculus*; as much as can be contained at once in the hand.

MANJAPU'MERAM is a large tree common in the West Indies; *nyctanthes arbor tristis* Lin. Sp. Pl. 8; its flowers are distilled, and the water is used in inflammations of the eyes. See Raii Historia.

MANJE'LLA KU'A. See CURCUMA.

MA'NNA, (from the Syriac term *mana*, a gift; as it is supposed to be the food bestowed by God on the children of Israel). *Manna Calabrina*, *ros Calabrinus*, *aeromeli*, *alusar*, *drosomeli*; and when of a rosy colour, *nuba*.

The miraculous food bestowed on the children of Israel is said to have been more probably sugar than manna, as it exuded on the reeds and grass; but it fell also on the stones, and was mouldy and fetid if kept beyond the day, except *that day was the sabbath*. It could therefore be neither, but a miraculous substance, of which we can form no idea.

The officinal manna has been supposed to be an exudation from the *fraxinus ornus* Lin. Sp. Pl. 1510; but on this subject authors speak with indecision and doubt. In fact it is produced from the *fraxinus* with the rounded leaf: the leaf of the *f. ornus* is smaller and pointed. Later naturalists have called these species the *f. rotundifolia*; and a full description of the tree is given in the Memoirs of the Society of Agriculture at Paris (an. 1788, trimestre d'Hyver) by Gaspard Carramone, who has examined it on the spot. We shall only transcribe from this memoir the distinction between the true species and the common ash.

The common ash is found in flat marshy places, particularly near the sea: the *ornus*, by which he means

the round leaved ash, on the cliffs of mountains. The surface of the bark of the former has not the white spots so conspicuous on that of the latter. The leaves of both are decomposed, but the last foliole of the common ash is always larger than the lateral folioles, which is not the case with the true manna tree. In the latter the leaf is unbroken and oval; in the former dentelated, and a long ellipsis.

The Calabrians distinguish different sorts of manna; the manna di spontana, which exudes spontaneously; m. forzatella, that which is procured by incision; m. di fronde, which exudes from the leaf; m. di corpo, which proceeds from the body of the tree. Manna flows spontaneously from the 20th of June to the end of July, from twelve at noon to the evening, in the form of a clear fluid. It is collected on the following morning if the night is fair, for otherwise it is washed off by the rain. This, when hard, is the picked manna, or the sorted manna of the shops. About the end of July, when the spontaneous exudation has ceased, incisions are made in the body of the tree, when more copious exudations take place, which fall to the ground like masses of wax. This, when dry, becomes reddish or brown, and is full of impurities.

What is collected from the leaves is styled grain manna, in little masses, about the size of a millet seed, and is found in the months of July and August. The Calabrians sometimes introduce a straw into the incisions, and the manna flows through and around it like stalactites, sometimes in very large pieces. This is very white and pure, called manna in tears. Many other species of the ash afford manna, and it has lately been found in asparagus, by M. Robiquet, *Annales d'Chimie*, vol. 55.

Manna resembles sugar in taste, but greatly differs from it in many other respects. Its sweetness is in a very small degree owing to its truly saccharine particles; for it admits only of a partial fermentation, and the product, though slightly vinous, never resembles alcohol (Dupuytren et Thenard, *Annales de Chimie*, Juillet, 1806). Ardent spirit dissolves a large portion of manna, which is almost wholly deposited in cooling, so as to fill the vessel with the precipitate, and with nitric acid, a large proportion of mucous acid is produced. It is chiefly, therefore, a mucous substance; and these experiments explain why, even in large doses, it does not produce heartburn, or prove in any degree inconvenient during pregnancy.

The finer manna of commerce is in oblong, roundish, single pieces; or in stalks, moderately dry, friable, of a whitish or pale yellowish colour, light, and somewhat transparent; internally it is seemingly composed of fine capillary crystals. The inferior kinds are moist, unctuous, brown, mixed with small pieces of wood and other impurities, and in irregular lumps; the manna di corpo before described.

The whitest, driest, lightest, purest, the most crystalline, and that slightly pungent to the taste, is preferred. The manna in flakes is supposed to be the best, but the smaller pieces are as good, if white, or of a pale yellow colour, very light, of a sweet not displeasing taste, and free from impurities. The fat honey like manna hath either been exposed to moist air, or is damaged by sea water, or a mixture of oily substances.

Manna is often adulterated by compositions of coarse

sugar, starch, and some purgative medicine, as scammony; but the fraud is discovered by the taste, weight, compactness, want of transparency, and its chemical affinities.

This concreted juice liquefies in a moist air, dissolves readily in water, and, by the help of heat, in rectified spirit, leaving only the impurities. A great part of the saturated spirituous solution separates on cooling, concreting into a flaky mass, of a snowy whiteness, and a very grateful sweetness: the remaining fluid, when inspissated, is unctuous, dark coloured, and disagreeable.

Manna is one of the mildest purgatives, and may be given with great safety to children and pregnant women, to the delicacy of whose frames and situation it is particularly adapted; it is an useful auxiliary to the purgative neutral salts, sheathes acrimony, is beneficial in coughs and disorders of the breast, particularly such as are attended with fever and inflammation, and in bilious complaints; but is apt to create flatulencies and cholics, which are prevented by a warm carminative. It purges in doses of from ℥ i. to ℥ ij. and this quality is increased by a small addition of cassia. When administered in bilious disorders, Geoffroy recommends quickening it with a small proportion of antimonium tartarizatum, to evacuate the bilious serum without nausea or colic. Sydenham recommends the addition of lemon juice to manna, as a remedy for the gravel, and adds, that the acid renders the manna a quicker purgative, diminishing at the same time the nausea which it sometimes excites, renders it easy on the stomach. In bilious complaints tamarinds are usefully joined with manna. In the gravel, the hooping cough, and when all possible irritation should be avoided, the manna may be given in milk. Modern practice does not very often employ this medicine alone, for the dose is so large as to cloy the stomach, and produce nausea. See Raii *Historia*; Tournefort's and Lewis's *Mat. Med.*; Neumann's *Chemistry*.

MA'NNA THU'RIS. See OLIBANUM.

MA'NNA TERE'NIABIN, and TRANGEBIN. See ALHAGI.

MANNIFERA A'RBOR, (from *manna*, and *fero*, to bear). See MANNA.

MANSORIOUS MUSCULUS, (from *mando*, to chew). See MASSETER MUSCULUS.

MANT'LE, (from *manus*). The name of a bandage.

MA'NUS, (from *manah*, to prepare, Chald.). The HAND is divided into the carpus, metacarpus, and fingers. The posterior part is convex, for greater firmness, and the internal part concave, for the convenience of grasping. The concave side is called the palm of the hand.

MA'NUS DE'I. A resolvent plaster described by Lermery: an appellation also of opium.

MANY'L-RARA. A tall tree, growing in the East Indies. Its fruit resembles an olive, and is eaten to promote appetite and digestion. The plant is not included in any system.

MAY. See MANGA.

MARA'NDA. A plant resembling the myrtle, not yet reduced to any genus, growing in the island of Ceylon: a decoction of the leaves is recommended in the venereal disease.

MARA'NTA GALA'NGA. See GALANGA.

MARASMO'DES. A hectic fever in its last stage.

MARA'SMUS, (from *μαραινω*, to render lean,) an ATROPHY. (See ATROPHIA.) The species also of hectic fever common and fatal to old men.

MARATHRITES, (from *μαραθρος*, fennel). See FENICULUM.

MARATHROPHY'LLUM, (from *μαραθρος*, and *φυλλον*, a leaf). See PEUCEDANUM.

MARA'THRUM, (from *μαραινω*, to wither; because its stalk and flower wither in the autumn). See FENICULUM.

MARCASI'TA. (German.) See PYRITES and BISMUTHUM.

MA'RCHED. See LITHARGYRUM.

MARCHI'ONIS PU'LVIS. MARQUIS'S POWDER, of the Leyden dispensatory, designed as an anti-epileptic, consisting of peony roots, misleto, elk's hoof, coral, ivory, &c.

MA'RCOR. A preternatural drowsiness.

MARCO'RES, (from *marceo*, to become lean,) the first order of Dr. Cullen's class *cachexia*, which he defines, diseases attended with wasting of the whole body. It is similar to the Macies, and Emaciantes, of other authors.

MARGARI'TTÆ, (from *margarita* a pearl,) *pirle*, *uniones*, PEARLS, are small morbid excrescences, of a calculus kind, of a bright semi-transparent whiteness, formed on the inside of the shell of the *concha margaritifera*, or mother of pearl fish; of oysters, muscles, and other shell fish. The finest pearls are brought from the East, inferior ones from the West Indies, and our own shores. The oriental have a more shining silver hue than the occidental, which are somewhat milky. Those not fit for ornament are called rag and seed pearls, and are employed in medicine.

True pearls in the fire become quick lime, and readily dissolve in all acids, except the vitriolic. They resemble, therefore, oyster shells, and have no virtue but what is common to these substances. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

MARGARI'TA, (a rabbinical term, *margalith*). See STAPHYLOMA and ALBUGO OCLORUM.

MARGINA'TUS, (from *margo*, a margin,) BORDERED, applied to the seeds of plants which have a thin leafy border round them.

MARI'NUM, vel MARINUS SAL, (from *mare* the sea). SEA SALT; *esebon*; *communis*, *culinarius*, et *cibarius sal*; COMMON SALT.

The salt is not only extracted from the sea water by evaporation, but is also found in extensive strata. (See GEMMA SAL.) It is composed of the marine acid, and the mineral alkali; dissolves in about thrice its weight of cold water, though, when heated, it scarcely requires less.

The solution of this salt, if gently evaporated, affords cubical crystals, which are the common or alimentary salt. A small quantity of the sal catharticum amarum is next produced; but the chief part of this salt remains in what is called the mother water, which is oily, and on that account will not admit of its farther crystallization.

Common salt, when dried in the temperature of 80°, contains 38.88 of acid, 53 of soda, and 8.12 of water: by others the acid is said to be 33.3, and the alkali 50. Its specific gravity is 2.120; it decrepitates in the fire, renders water colder than before, though, from the addition, it is more difficult to freeze. Common salt is the

most generally useful condiment, and the best antiseptic to preserve meat from putrefaction, and butter from rancidity. It furnishes a firm and cheap glazing for earthen ware, and is of considerable use in the process of dyeing. The separation of soda from sea salt is a problem of considerable importance in the arts; and it has been completely solved, if the removal of the duty on salt would render it practicable with advantage. This is not the place for disquisitions not connected with medicine; but we may remark, that iron, litharge and lime, in proper circumstances, will effect the decomposition. The lime in the soil of Egypt and Tripoli seems the means by which the soda has been separated in such considerable quantities. Acetite of lead will equally effect the separation of the alkali; but it is too dear for commercial purposes.

In the animal economy common salt is of general utility. (See CONDIMENTS.) It seems to check putrefaction; but is of more service as a general stimulant. Animals pine when deprived of it, and few nations have been found who have not added this condiment to their food. In the animal process the fixed alkali is seemingly changed to the volatile, and we have suspected that the muriatic acid is changed to the phosphoric. Chemistry has not yet elucidated this subject, and we offer it chiefly as a conjecture which we could support by inductive reasoning, were this the place for such disquisitions. Beyond its general stimulus we do not perceive any salutary action of sea salt in the proportion usually taken. In large quantities it is used as an emetic, as a remedy for hæmorrhage from the lungs, and in the form of sea water as a laxative and a remedy for scrofula. (See HÆMOPTYSIS and AQUA MARINA.) Externally it is used in palsies, and in apparent death from drowning. In these cases, as in almost every other, it seems to act as a simple stimulus only.

The sea water, gradually evaporated by the sun's heat, on the rocks, or in circuitous canals made for this purpose, is called bay salt, and is formed into large crystals; it does not liquefy in a moist air, and is more powerfully antiseptic.

Spiritus salis marini Glauberi, or the muriatic acid, is made by gradually adding six pounds of vitriolic acid, mixed with five pounds of water to ten pounds of dry sea salt: the acid is then separated by distillation. In this state the acid comes over in a gaseous form, and requires condensation by means of water. As a gas it is elastic and invisible, incapable of supporting animal life or flame, has a pungent smell, and acid taste, and a specific gravity nearly of .002315, about double that of common air. Water absorbs it copiously and freely; but it is unchanged by the strongest light and heat. Ice absorbs it also, but boiling water admits of no union with it. In the process just described, the acid of vitriol unites with the mineral alkali, leaving its acid free, which rises in distillation; and, in the usual form, that of a colourless or a pale yellow fluid: its specific gravity is 1.196, though the acid of commerce is seldom more than 1.17. The strongest liquid acid is supposed by Mr. Kirwan to contain about an equal part of water. The dryest gas contains a small portion of water, which is only separated by electrical explosions.

The specific gravity directed by the college is to that of distilled water, 1.170, to 1000.

The muriatic is the weakest of the mineral acids, but

stronger than any of the vegetable kind: it requires a greater fire to distil it than that of nitre, yet it is more readily dissipated by the action of the air. It has no effect on oxygen gas or inflammables. The muriatic acid oxidates metals, but requires for all, except iron, a greater or less degree of heat. It combines with all alkalis, earths, and the greater number of metallic oxides.

Its composition (see CHEMISTRY) is not yet ascertained. The latest experiments are those of M. Brugnatelli, in the sixty-second volume of the *Journal de Physique*, p. 298. He certainly found the muriatic acid produced, when the galvanic fluid was passed through water, by means of gold, platina, iron, or the black oxide of manganese; but some other metals, particularly silver, produced, in the water, soda. We can connect this only with one fact, that water, evaporating from iron, produces a positive electricity, and from silver a negative. In these experiments of De Saussure it is, however, clear that the water is decomposed rather than evaporated. In Brugnatelli's experiments the positive pole seemed to produce in the decomposition of the water the acid, and the negative the soda.

It is chiefly used as a tonic and antiseptic, in the dose of from ten to sixty drops, in water, or any other convenient liquid. In putrid fevers, after having cleansed the primæ viæ, it supports the strength, and corrects any remaining putrefaction on the contents of the stomach and bowels; but seems not to carry its antiseptic quality into the general mass, which indeed is seldom in a putrid state. It was Recht's boasted remedy for fevers, which the Prussian government bought at a considerable price. In bilious fevers it has been recommended; but it is not peculiarly useful, and, in general, its good effects are confined to the parts in immediate contact with it.

In acidulated gargles for ulcerated throats it has been strongly recommended, but seems to be in no respect superior to the vitriolic acid; and, diluted with the tincture of benzoe, has been applied, it is said, with success to putrid ulcers.

Linnæus remarks, that, if properly diluted, and applied to chilblains, it radically cures them. If half an ounce of good bay salt is dissolved in four ounces of water, and two drachms of the muriatic acid be added, it will form a mixture, of which a tea spoonful, in a glass of water, is said to improve the appetite, and frequently stop vomiting.

The muriatic acid, combined with volatile alkalis, produces the officinal sal ammoniac; with fixed vegetable alkali the sal digestivus Sylvii; in modern language, muriated potash. See CHEMISTRY.

The acidum muriaticum, combined with calcareous earths, forms a calcareous muriat, which deliquesces in the air, and dissolves both in water and in rectified spirit of wine. It is contained in a considerable quantity in sea water, but remains in the mother water after the crystallization of the muriated soda, and is said to be antiseptic, diuretic, and lithontriptic. The medicine, commonly sold under the name of *liquid shell*, appears to consist only of calcined shells dissolved in marine acid. These combinations are made by mixing the calcareous earth with sal ammoniac, and urging the mixture with a gradual fire, until the volatile alkali of

the salt is either dissipated or collected by sublimation when the acid unites with the earth.

The *muriat of lime* has lately become a fashionable remedy in scrofula, in scirrhi, and other diseases supposed to arise from inspissated lymph. From half a drachm to half an ounce, diluted with water, is given, according to circumstances, every day.

For the *murias ferri*, v. FERRUM; and for the *murias barytis*, v. BARYTES.

See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

MARIPE'NDAM, is a plant in the island of St. Domingo. The distilled water from its tops is greatly esteemed in pains in the stomach. The plant has not been properly examined. See Raii *Historia*.

MARI'SCA, a FIG. An excrescence about the anus, like a fig. See CONDYLOMA and HÆMORRHOIDES.

MARI'SICUM. See MERCURIALIS FRUCTICOSA.

MARJORA'NA, (*marjorana*). See ORIGANUM.

MARMARY'GÆ, (from *μαρμαρίζω*, *resplendo*,) a variety of *pseudoblepharis imaginaria*. Sparks or corruscations which seem to flash before the eyes, from a fulness of the vessels of the brain.

MARMOLA'RIA, (spotted like *marble*). See ACANTHUS.

MA'RMOR, (from *μαρμαρίζω*, *to shine*). MARBLE. A calcareous stone, chiefly used for the carbonic acid gas it contains, employed in preparing the acidulous mineral waters. See CALX.

MARMORA'TA AU'RIMUM. See CERUMEN.

MARMO'REUS TA'RTARUS, (from its hardness). See CALCULUS.

MARMORA'CEA VENE'NA. Such poisonous substances as are fatal in doses not exceeding the bulk of a grain of wheat.

MAROCO'STINUM. The epithet of a cathartic extract originally made by Mindererus, in which marum and costus are ingredients, designed for discharging serous humours, but now neglected. See Pharmacopœia Augustana. *Pillule marocostine* Lemery and Bates.

MARO'TTI. A tall tree in Malabar, with leaves like those of the bay tree, and a fruit which contains an oily kernel. The oil expressed from the kernel is often medicinally used by the natives. (See Raii *Historia*.) It has been figured by Reed, in his plants of Malabar, vol. i. pl. 36, but has not been reduced to a place in any system.

MARRUBIA'STRUM. See BALLOTTE.

MARRU'BIUM, (from the Hebrew terms *mar rob*, a bitter juice). HOREHOUND; *mauromarson*; which rather means the black sort. It is also a name for the *cardiaca*, *leonurus cardiaca* Lin. Sp. Pl. 817, and some other plants.

MARRU'BIUM ALBUM; *prasium album*. COMMON WHITE HOREHOUND, *marrubium vulgare* Lin. Sp. Pl. 816, is a hoary plant, with square stalks, and roundish unwrinkled leaves, set in pairs on long pedicles, from the bosoms of which arise thick clusters of whitish labiated flowers, in striated cups, whose divisions terminate in sharp points or prickles. It is perennial, grows wild in cultivated grounds, and flowers in June.

The leaves have a slight aromatic, but not at first an agreeable smell; their taste is bitter, penetrating, diffusive, and durable in the mouth: in large doses they

prove laxative. This plant is said to be an useful aperient and corroborant, in humoral asthmas, pulmonary consumptions, cachexies, menstrual suppressions, scirrhus affections of the liver, jaundice, and several other chronic disorders. The ancients had an high opinion of its efficacy, particularly in pulmonic and visceral obstructions; and, amongst the common people, horehound tea in coughs and asthmas is a common remedy. Dr. Cullen disputes its virtues as a pectoral, as well as a deobstruent, and thinks the authorities of Forrestus, Zacutus, Lusitanus, and Chomel, very insufficient. A drachm of the dried leaves in powder, two or three ounces of the expressed juice, or an infusion of half a handful of fresh leaves, are commonly directed as a dose. See BOICENGA.

The dry herb gives out its virtues both to water and to spirit. The expressed juice, gently inspissated to an extract, is the best preparation: the dose is from gr. x. to ʒss.

MARRU'BIUM AQUATICUM, *lycopus Europeus* Lin. Sp. Pl. 30, WATER HOREHOUND, found on the sides of brooks, but inferior in virtue to the white.

MARRU'BIUM NI'GRUM FE'TIDUM. See BALLOTTE.

MARRU'BIUM VERTICILLATUM, *narrubium Hispanicum* Lin. Sp. Pl. 816; Galen's MAD WORT; the BASE HOREHOUND. These species are usually neglected. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

MARRULLIUM. See LACTUCA.

MARS DIAPHORE'TICUS. See FERRUM.

MARS SACCHARATUS, and SOLUBILIS. See FERRUM.

MA'RSAS. See BONDUCH INDORUM.

MARSUPIALIS, (from *marsupium*, because it is shaped like a purse). See OBTURATOR EXTERNUS and INTERNUS, and GEMINI.

MARTIANUM UNGUENTUM. Martian's SOLDIER'S OINTMENT. R. Ol. laur. f. ℥iij. foliorum rutæ, recent. ℥ij. ss. majoranæ ℥ij. menthæ ℥i. salviæ. absynth. communis. balsamitæ maris et basici, āā ℥ss. olei olivæ, ℥xx. ceræ flavæ ℥iv. vini Malagens, ℥ij. m. f. unguentum. This was employed to preserve the limbs of soldiers from the injuries of cold in the camp.

MARTIANUM POMUM. See AURANTIA HISPAN.

MARTIS ESSENTIA, OLEUM PER DELIQUUM, SAL, TINCTURA, and EXTRACTUM. See FERRUM.

MARUM, (from the Hebrew term *mar*, bitter,) *sampsuchus*, *clinopodium-mastichina Gallorum*, *thimbra Hispanica*; *Jaca Indica*, MASTICH THYME, or COMMON MARUM, *thymus mastichina* Lin. Sp. Pl. 827, is a low shrubby plant, with small oblong leaves, pointed at both ends, set in pairs without pedicles; at the tops of the branches stand woolly heads, containing small white labiated flowers, whose upper lip is erect and cloven, the lower divided into three segments: each flower is followed by four seeds, inclosed in the cup. It grows spontaneously on dry gravelly grounds in Spain, and in similar soils it bears the ordinary winters in England. Its virtues are similar to those of the Syrian marum, but less powerful.

MARUM SYRIACUM, vel CRETICUM, *majorana Syriaca vel Cretica*, *marum cortusi*, *chamædrys incana maritima*, MARUM GERMANDER, of SYRIAN HERB MASTICH, *teucrium marum* Lin. Sp. Pl. 788, is a low shrubby plant, with small oval leaves, pointed at each

end, and set in pairs without pedicles, of a dilute green colour above, and hoary beneath; in their bosoms appear solitary purple labiated flowers, each of which is followed by four roundish seeds inclosed in the cup. It is said to be a native of Syria, and does not bear our winter's cold without shelter.

The leaves are bitter, pungent, and aromatic to the taste; their smell excites sneezing; and they agree with the canella alba in their virtues.

This plant loses but little in drying, gives out its active matter partially to water, but completely to spirit; the watery infusions retain the smell, but little of the taste; the tinctures retain more of the taste than the smell. Distilled with water, it yields an highly pungent, volatile essential oil, stronger than that of scurvy grass, and of a less perishable pungency; the remaining decoction is bitterish. Rectified spirit carries off only a part of the smell and pungency of the marum. This plant is supposed to possess very active powers, and to be an important remedy in cachexy, hysteria, and nervous debility, acting as a warm tonic and a powerful emmenagogue. The dose is ʒss. of the powdered leaves given in wine. In the present practice it is chiefly used as a sternutatory, and is one of the ingredients of pulvis asari compositus of the London Pharmacopœia. See Raii *Historia*; Lewis's and Bergius' *Materia Medica*.

MA'RVISUM. See MALVASIA.

MASCHALE, (μασχαλη). See AXILLA.

MASCHALISTER, (μασχαλιστηρ). See SPINA.

MA'SLACH. A form of opium used by the Turks.

MA'SPETA, and MA'SPETUM. See SILPHIUM.

MA'SSALIS, and MA'SSARIAM. See ARGENTUM VIVUM.

MA'SSÆ AD FORNACEM. See CANDELA FUMALIS.

MASSE'TER MUSCULUS, (from *μασσομαι*, to eat). *Lateralis*, *manducator mansorius*. The MASSETER MUSCLE rises on each side from the check bone and the interior part of the zygomatic process of the os temporis; and is inserted into the whole length of the lower jaw, particularly the angle.

MA'SSOY, a species of bark mentioned by Ray, from a tree hitherto undescribed. It is gratefully fragrant and heating.

MASTICATIO, (from *mastico*, to chew,) *manducatio*; *commanducatio*. Mastication comminutes the parts of our food, and intimately combines it with the saliva and mucus of the mouth. Due mastication is essentially necessary to digestion; but it is doubtful whether any portion of our food is absorbed during this process; for every thing which has not passed through the operation of digestion seems to be injurious when mixed with the circulating fluids. V. DIGESTIO.

MASTICATO'RIMUM, (from *mastico*, to chew). A MASTICATORY. See APOPHLEGMATICA.

MA'STICHE, (from *μαστω*, to express). MASTICH. See LENTISCUS.

MA'STICHEN. ODORATUM FUNDENS. See NUX VIRGINIANA.

MASTICHINA GALLO'RUM, (a dim. of *mastiche*). See MARUM.

MASTOIDÆUM FORAMEN. See STYLLOMASTOIDÆUM FORAMEN.

MASTOIDÆUS MU'SCULUS, (from *μαστος*, a nipple, and *ειδος*, forma, the mastoid process, resembling a nipple,) *sterno mastoides*, *sterno mastoidæus* of Dr. Hunter, who observes that it rises by two distinct portions from the sternum, with that part of the clavicle articulated to the sternum, and is inserted into the mastoid process. This last portion Albinus considers as a distinct muscle, and calls it *clino mastoidæus*, but it is not divisible from the other without art. Winslow calls this muscle *mastoidæus anterior*, or *sterno mastoidæus*; and the splenius the *mastoidæus superior*.

MASTOIDÆ'US LATERA'LIS. See **COMPLEXUS MINOR**.

MASTOIDÆ'US PROCE'SSUS. See **TEMPORUM OSSA**.

MASTOIDY'NIA, (from *μαστος*, a nipple, and *οδυνη*, pain). **SORE OR PAINED NIPPLES**. But more commonly pain in the breast from inflammation. See **INFLAMMATIO MAMMARUM MULIERUM**.

MASTURBATIO; *manustraphatio*, *Onanismus*, the sin of Onan, from a perverted passage in the Pentateuch. The discharge of semen from a preternatural stimulus; the vice, it is said, of the solitary monk, and, perhaps, of other recluses, to whom more natural enjoyments are denied. It is a habit of the most destructive tendency, enervating, in the highest degree, both the body and mind. Nature seems to have fixed a strong mark on those disposed to every unnatural enjoyment, and however secret their practices may be, so indelible is this mark, that they cannot escape detection from that *tact* which has been peculiarly distinguished by the term of *sensus medicus*. In general, the countenance is sallow, with a peculiar dejection in the look. The voice is hurried and unsteady; the face often covered with dark coloured pustules, hard in the skin, and the whole frame displaying peculiar debility. The dejection, at times, almost amounts to insanity, and every complaint appears to threaten instant death. The tremor and apprehension prevent the natural enjoyments, by which they might be otherwise weaned from this destructive habit; and the whole life is alternated with doubts, apprehensions, and despair. Unfortunately, the practice is never forsaken, at least, notwithstanding every assurance, we have reason to think so.

The apprehensions of discovery and the despair render those unfortunate persons the dupes of quacks, and it may be remarked, that every quack bill holds out delusive hopes to those who experience the bad effects of such indulgences. Regular practice exhausts the whole tribe of tonics and stimulants with little effect. The warm balsams, of which the quack medicines consist, are either rejected from the hands of the physician, or not continued a sufficient time; and even cold bathing, the best remedy, does not fix the imagination so strongly as the solar tincture, or the balm of Gilcad. If not too long continued, a prudent marriage may recover the patient; but it would be unjust, cruel, and impolitic, to condemn a healthy young woman to the shadow of a man. This remedy, however, we have often found effectual in cases where the constitution was not wholly exhausted.

Tissot on Onanism, and the Appendix to his Dissertation on Bilious Diseases; Gruner and Husche Dissertationes de Masturbatione.

MATALI'STA, MATBALI'STIC. See **JALAPA**.

MA'TER, (from *μαω*, to desire). See **DURA MATER**.

MA'TER PERLA'RUM, *concha margaritifera*, *concha*

mater unionum, *concha valvis æqualibus*, *nacre*. **MOTHER OF PEARL**. This is the pure pearl like part of the shell in which pearls are found, possessing the antacid properties of the pearls themselves. See **MARGARITÆ**.

MATERIA, (from *mater*, a mother). **MATTER**; **SUBSTANCE**. In strictly logical disquisitions, *material* is in opposition to *modal*, the one signifying as a cause, a substance, the other a peculiar state; thus a sword inflicting a wound is a material cause of pain, spasm only modal. To come nearer, a calculus in the gall duct is a material cause, the same effect from violent passion modal only. This is nearly the meaning of Dr. Cullen, when he distinguishes sensation of impression from sensations of consciousness; but this distinction is seldom attended to in the indiscriminating, flowery, pages which by courtesy are now styled medical. If we were to refer to works where strict logical discrimination is pursued with rigour, they would be those published during the presidency of Stahl at the university of Halle. The minute precision of the author's reasoning (Stahl himself) is highly gratifying, while the obscurity of the language and manner would repel every modern reader.

MATERIA MEDICA. The last article suggests to us a logical inaccuracy in the title, which strictly implies *material* substances employed in the cure of diseases. We must, however, extend these views, and, with the spirit of the best authors, follow their example, by considering, under this title, every means of relieving the maladies to which human nature is subject. The field which this inquiry opens to our view is immense. It not only includes a consideration of the properties and use of each of these means, but the mode of investigating these properties, of arranging our copious list of remedies, so as to assist not only our explanations of their virtues, but the choice of our remedies in any given emergency, and to point out the distinctions which, from different circumstances, may guide us in our preference of one to another. Not the least important object in this disquisition is the conduct and merits of the different authors in this department of medicine.

The knowledge of medicines must have been coeval with the existence of the human race. Mankind was always subject to diseases and accidents, and would naturally seek for remedies. There is consequently no race, however uncultivated, but has its *materia medica*, and modes of cure, often rash, violent, and injudicious, but sometimes discriminated with precision, and adapted with skill. It were to be wished that botanical inquirers had more often, in their itineraries, preserved these rude modes of treatment as Linnæus has done in his *Flora Laponica*. The scattered limbs, however, exist, and will repay the trouble of collecting.

The Greeks, who made every thing their own, and often created a fabulous personage, to whom they gave the honour of a discovery, for which they were indebted to their neighbours on the continent of Asia, attributed the achillea to Achilles, the teucrium to Teucer, and the artemisia to Artemis. Their famous *Æsculapius* was probably only an Egyptian title (*haskelab*), the father of wisdom. The *materia medica* of Hippocrates (for it would be to fill our pages very uselessly to copy all the fables recorded on this subject) was very

simple; but even the few remedies which he employed were in part rejected by Erasistratus. The empiricism and credulity of Serapion and his followers introduced numerous disgusting and ridiculous remedies; many of which were continued in the foreign pharmacopœias in the last century, and Vogel even condescends to notice several of them. Themison, the supposed founder of the methodic sect, gibeted in the satires of Juvenal as a most unsuccessful practitioner, recommended medicines of activity, as the aloes, the scammony, &c. He first employed leeches, and preferred these and cupping glasses to general bleeding. He seems to have rejected with indignation the ridiculous remedies of the empirics; but if we may trust his copyist Cœlius Aurelianus, employed some which were scarcely less absurd. The rage for compound medicines seems to have begun with Themison, but it increased with his followers, particularly Andromachus and others, down to the era of Galen, to whom the materia medica is greatly indebted for his attentive inquiries into the nature and country of the different medicines, though the real knowledge of their effects was obscured by the numerous ingredients of each formula. The authority of Galen, and the use of compound medicines continued, we know, for many centuries; and we have not long escaped from the trammels of his authority.

While, however, the infallibility of Galen remained unquestioned, the Arabians greatly enriched the materia medica by those medicines which their climate, or their connection with India, had introduced to their notice. The purgatives of their predecessors were the mild herbaceous vegetables, or the more acrid drastics; but the Arabians introduced the manna, senna, and myrobalans. They varied also the formulæ, and rendered them more agreeable by the addition of syrups; and they were undoubtedly acquainted with distillation, though they seem to have only employed this process in the preparation of simple waters and distilled oils. They added also musk, mace, cloves, &c. which are still retained; the precious stones, leaf gold, and silver, which are now neglected. They injured this branch of medicine by their fondness for compounds, in which they exceeded the Greeks; and, by their hieroglyphics, their metaphorical language, their comparison of the stars with diseases, and the metals with remedies, are supposed to have occasioned those wild extravagances which for ages led philosophers in pursuit of the art of making gold, and physicians in that of compounding an universal medicine.

Whether this latter conjecture of Boerhaave is well founded or not, the chemical physicians soon succeeded, and the language of Bacon, the earliest of these in the thirteenth century, seems to prove that the torch was lighted from the Arabian flame. Bacon endeavoured only to ward off old age; with Raymond Lully, in the following century, the pursuit of the universal medicine commenced. This pursuit was continued, and the materia medica greatly augmented, by acquisitions from chemical preparations by the Isaacs, Basil Valentine, and many others, down to Paracelsus and Van Helmont, the last of whom lived in the beginning of the 17th century. The absurdities of this sect are inconceivable; but they were succeeded by philosophers and physicians, who pursued the same path with more rational

views and better success. Sylvius de le Boe, Tachenius, Quercetanus, Glaser, Schroeder, Lemery, Glauber, and others of the chemical school, the great benefactors of the materia medica, have in succession greatly enriched this science with the chemical remedies which we still employ. During this period the appearance of the lues venerea also added to the materia medica the sarsa, the guaiacum, the china, and some other medicines.

The discovery of Harvey, in the beginning of the seventeenth century, gradually turned the attention of practitioners from the active remedies of the chemists to those which were supposed to act mechanically; and mechanical reasoning soon overturned the whole system of medicine, and changed the language which had been hitherto held respecting the operation of remedies. The good sense of Boerhaave led him to retain the remedies of the chemists while he employed and extended the language of the mechanical physicians, while he studied and enforced the medical observations of Hippocrates and his successors.

With the downfall of the humoral pathology the materia medica experienced little improvement. Dr. Cullen, who, like Boerhaave, was a chemist before he had completed his medical system, still retained a predilection for chemical remedies, and for the more active forms. He introduced, it is said by Dr. Fordyce, the emetic tartar; and he supported, by his recommendation, the corrosive sublimate, not only in lues, but in diseases of the skin: a remedy employed externally for this latter complaint by the Arabians. We mention chiefly these circumstances to speak of a new sect, the introducers of medicines formerly accounted poisonous. Van Swieten, by his adopting the use of the corrosive sublimate from the Russians, seems to have first excited the attention of the physicians of Vienna to the vegetable poisons, the hemlock, the aconite, the belladonna, the napellus, the phytolacca, lactuca virosa, &c.; an impulse followed by the introduction or revival of the digitalis, the arsenic, &c. It is not our present object to appreciate the value of this new step; for it belongs to the separate articles. In general, however, we may add, that the real merits of the greater number have by no means answered the expectations excited. Our materia medica, as established by the decision of the colleges of London and Edinburgh, is, at present, confined in the number of its articles: but these are well chosen, active, and effectual. Each practitioner will probably add, from his own predilections, some others; but others, we suspect, will not be found necessary.

THE ACTION OF MEDICINES depends on a relation between their properties and the living solid, differing in different parts of the system. This relation is, in general, obscure. It is, however, sometimes, and perhaps more frequently than has been supposed, chemical; sometimes purely physical; scarcely in any instance mechanical. It is occasionally connected with the more obvious properties, as the smell and taste of the medicine, but confined in this respect to the vegetable, less strictly to the animal, kingdom. It is sometimes connected with the chemical analysis, or with the natural affinities of a plant. Each mode has been employed in investigating the powers of medicines, and to each we must direct our attention; not perhaps as of

peculiar importance, for few medicines have been discovered in this way, but to explain the language and the conduct of authors, and sometimes to correct them.

The olfactory organs are peculiarly acute in the brute creation, but of no great importance to us in our investigation of the properties of medicines. The utility of the SMELL is limited chiefly to vegetables: but few animal substances discover their powers by these organs, and the insects and the vermes are either without smell, or give faint indications of their qualities in this way. In general, pleasing smells are salutary, and nauseous or fœtid ones injurious. Pleasing and nauseous are, however, relative terms; and to our neighbours on the continent the fumet of tainted venison is highly gratifying. Authors who have investigated the powers of medicine by the smell are Linnæus and Lorry, each of whom we must notice, as they have considered the subject in very different views; while former authors, as Boyle, considered effluvia chiefly as philosophers, and contemplated only the surprising divisibility of matter; or, as Boerhaave, Venel, and Roux, treated of odour as chemists, and endeavoured to separate or combine it in a more durable form.

Linnæus divides the odours of medicines (*Amœnitates Academicæ*, iii. 183.) into AROMATIC, FRAGRANT, AMBROSIACAL, ALLIACEOUS, HIRCINE, STINKING, and SICKLY. The three first are pleasant, the three last disagreeable, smells. This enumeration is not perhaps correct, nor the classes distinct; but the Linnæan language is employed by many respectable physicians of his school, and consequently merits our attention.

The *aromatic* smell is distinguishable in various families of plants, as the laurels, the umbelliferæ, and the labiatae, and is found in every portion of a vegetable, often in every part of the same plant. The iris, the rosemary, and the sage; lavender, *flowers*, and pinks; canella and winter's *bark*; sassafras *wood*; laurel *berries*; cummin and carui *seeds*; gum benjamin and balsam of capivi, are striking instances of it. They are generally stimulating, not without a suspicion of a narcotic power; often induce the calm serenity which we feel from tea, and destroy irritability rather than give strength. The exhalations themselves, from the experiments of Ingenhouz, are chiefly azotic, and, in many constitutions, highly deleterious.

The *fragrant* smell is not very clearly defined. It contains some of the more pungent smells, and seems to be a connecting link between the aromatic and the ambrosiacal. The instances are the flowers of the lily, the jessamin, the tuberose, some species of pinks, and saffron. They are more actively anæsthetic than the fragrant odours, and more certainly antispasmodic.

The *ambrosiacal* smells are very penetrating and active, when concentrated, as in ambergris and musk, but generally disagreeable. When greatly diffused they are more agreeable. The species of geranium, mallows, rose, and garlic, styled *moschate*, are of this kind; the fruits of the pine apple, of some kinds of apples and pears, musk, civet, and burnt animal substances, are instances of this species of odour. They appear to be stimulant, but are strictly sedative, and powerfully antispasmodic.

The *alliaceous* smell is particularly distinguishable in

garlic, and its congenères, in the scordium, asafoetida, and what are styled the warm fœtid gums. These odours belong to very active stimulants, which powerfully excite the vessels of the skin, and increase the discharge not only from these but from every gland in the human body.

The *hircine* smell is that which resembles the odour of the goat; and, in the vegetable kingdom, we find it in the herb robert, the orchis, some mushrooms, particularly the phallus impudicus. In general, these fetids are sedative, and often deleterious.

Stinking smells are exemplified in opium, nightshade, and hemp, which are all narcotics; and the *sickly* in hellebore, tobacco, colocynth, putrid meat, senna, and rhubarb. All such substances are powerfully emetic, and, if they escape the stomach, are also cathartic; and all are narcotic.

M. Lorry has proceeded in a different way, and has considered the smells, which are essential to the medicine, and which continue, independent of very minute analysis. These are the CAMPHORATED, NARCOTIC, ETHERIAL, VOLATILE ACID, and ALKALINE.

The *camphorated* is found in the labiated, the composite, the terebinthinated, and the aromatic plants, as well as in the laurels and myrtles. Its characteristics are, extreme penetrability, a singular volatility, a strong attraction for oily and spirituous menstrua. Though easily dissipated in the air, yet, when united with resins, in the leaves of plants it is preserved from evaporation, and contributes to their preservation. This principle resists the activity of fire, and the most powerful agents. Even musk and opium will not disguise it: its medical power we have already detailed. See CAMPHOR.

The *narcotic* odour is that virose effluvia which destroys the principle of life. It exists in the poppies, the nightshades, the borrago, the cucurbitaceous and umbelliferous plants, with many others; often disguised by the distinguishing principles of the vegetable, and obvious when these are separated by putrefaction or fire. This is the most fixed and adhesive of all smells. It corrects the volatility of the others, and often disguises all, except the camphorated. Even in a small proportion it is discoverable among the most fragrant smells, as in the rose, the jessamin, the tuberose, and the violet. These flowers exhale the true narcotic odour, when their aromatic and camphorated smells are dissipated. This smell is simple, sometimes concealed under that of aniseseed or garlic, occasionally imitating the smell of radishes, or the offensive odour of bugs. The same odour is found in animal substances. Virgil speaks of the virosa castorea; and animal oils, though rectified by distillation, exhale this narcotic smell.

The *ethereal* odour is volatile, incoercible, and of extreme tenuity. It escapes so easily that we can only recognise it for a short time. Art produces its most striking example; but we find it in the pine apple, in melons, some kind of pears and apples, in strawberries, and the greater number of fruits which grow under the burning sun of the torrid zone. It is sometimes discovered on the first appearance of the sceptic process, to which sweet fruits are exposed. This odour combines with the alkaline, and the narcotic smell of opium giving it a striking volatility, and moderating its narcotic property. It unites also with camphor, and adds to its sedative and

soothing powers in a manner well known to practical physicians.

The *volatile acid* odour is usually combined with an aromatic volatile spirit. It is distinguished in lemons, oranges, gooseberries, cherries, &c. combined and disguised in many plants, as in the lemon thyme. This odour is in general pleasing and refreshing, and it destroys the effects of narcotics. It is often combined with the ethereal smell, as in the aromatic spirit of vinegar, and is destroyed by putrefaction.

The *volatile alkaline* smell is distinguished by a biting acrimony, which irritates the eyes. The horse radish, mustard, scurvy grass, with all the alliaceous vegetables, are examples of this odour, which is in part destroyed by acids. It is generally confined in plants by mucilages and oils, and is very durable, since even putrefaction will not wholly separate it. In *asafœtida* it is combined with the virose odour; and the most fetid smells seem to be combinations of this kind, which lead us to suspect some hepatic combination.

The TASTES of plants conduct us more certainly to their medical properties; but the similarity of terms may contribute, without care, to confound them with the smells. Our chief guide in this path is Linnæus himself; but Bergius, assisted by the comprehensive Linnæan language, has greatly extended our distinctions of taste; though employing terms and comparisons generally known, he scarcely requires an interpreter. Taste has been considered as a cause of the action of medicines, or at least as a means of discovering their properties in almost every era of medicine since that of Hippocrates; and, besides Linnæus, Wedelius, Walther, Hebenstreit, Koenig, and Tavvy, have paid particular attention to it. The two last have, however, confined themselves to mechanical explanations of taste; and, like Willis, have supposed acrid particles needles, oily ones spheres; bitter, salt, acid, and styptic tastes, owing to forked, irregular, polyedral, conical, or hooked particles respectively.

Tastes greatly differ; and though, as in smells, we say in general that substances of an agreeable taste are salutary, and those which are displeasing to the palate injurious, yet the question of pleasantness or its opposite is relative. Pungent tastes are universally painful; but, when diluted, they become agreeable. In fact, as we shall find in the operation of medicines, every thing in excess is stimulant: we only perceive either peculiar properties, or flavours, when the proportion is suitable to the circumstances. Fourcroy divides tastes into those which are highly pungent or painful, as the caustics; those which excite moderate sensation, as the sweets and bitters; such as only affect the stomach, and very slightly, if at all, the palate, as the antimonials; and such as act only through the medium of the nerves. We need not add that this is to extend the subject beyond its proper limits. It is singular, that the people on the coast of Malabar, among whom medicine is in a very rude state, divide their remedies according to taste. Grundler, the Danish missionary who visited that country in the beginning of the last century, has given an extract from the *Voya da-satyram*, which contains all their medical science, where the remedies are divided into acids, sweets, bitters, acrids, and astringents. We may just add, that Braun, the son-in-law of Haller, an officer

in our service in Indostan, has informed us, that, in the ancient seminary of Benares, no other part of medicine is cultivated except what relates to the virtues of vegetables; and in the Gottingen museum, a valuable hortus siccus of Malabar plants in twelve volumes folio, with their names and properties annexed, was some time since preserved.

Linnæus divides the taste of medicines (*Amœnitates Academicæ*, ii. 335) into the SWEET and ACRID; the FAT and STYPTIC; the ACID and BITTER; the VISCID and SALT; the WATERY and DRY. The *styptic* is a compound taste, sometimes consisting of the dry and acid, when it is styled *austere*; or of the dry and bitter, distinguished by the term *acerb*. The *nauseous* taste produces an inverted motion of the œsophagus and stomach. It is a compound, but its ingredients are not easily ascertained. We are informed by Quercetanus, that the medicines styled by Hippocrates bitter, acid, and sweet, are, by Galen, in conformity to his theory of the humours, called hot and cold, wet and dry.

The property of *sweetness* is conspicuous in the roots of the polypody and liquorice; all ripe fruits; in milk and in honey. The sweets, either saccharine or mucilaginous (vide MANNA) are, as we have seen, nutritious, chiefly adapted to dry, lean habits, and advanced life. They are also demulcent, and supposed to be expectorant; but the latter quality rests on a doubtful foundation.

Medicines distinguished by an *acid* taste are heating, irritating, and, in excess, corrosive. In large doses they are the most destructive poisons. Externally, they are rubefacient, sometimes discutient, or occasionally suppurative. By their general stimulus they promote every evacuation, and are sometimes the most active emetics. Their powers as cathartics are less conspicuous, and they are generally useful in cold, phlegmatic habits. Examples of this kind are the pure alkalis, and the metallic salts; the roots of bryony, pyrethrum, horse radish, and of the alliaceous tribe; the leaves of the soldanella, persicaria, tithymalus and cochlearia; the bark of the elder; the seeds of the mustard; euphorbium, gamboge, and cantharides.

The *fat* taste is conspicuous in the almond, cocoa nut, lintseed, and axunge. It is owing to an oil combined with a mucilage, and is lost when they become rancid. They are in general demulcent, and useful when the fibres are stretched, or the mucous membranes abraded. From this last circumstance, they sometimes relieve diarrhœas, though many of this class are naturally laxative.

The contraction of the mouth, which arises from tasting *styptics*, is sometimes communicated to other parts. Alum is a striking example; but it does not follow that styptic vegetables, as has been supposed, contain an argillaceous sulphat. We find this taste in vitriolated iron and zinc; the roots of tormentil, bistort, and quinquefolium; the barks of the tamarisk, the capparis, and the fraxinus; the gall nut; the leaves of the centinodium, the myrtle, and the oak; the flowers of pomegranate, and in red roses; the juice of acacia, catechu, &c. These remedies are, in general, astringent; and, as they all contain tannin in a considerable proportion, we find the foundation of their properties in the separation of the gelatin. See ASTRINGENTIA.

Of the *acid* taste we require no examples; but if we speak of this as a natural one, we must exclude the mineral acids, which rather belong to the styptics. With this exception, we shall find acid substances cooling and sedative, neutralizing in some degree the bile, and destroying putrid acrimony in the stomach. They allay thirst, promote a discharge from the kidneys, and often from the skin. They prevent accumulations of fat in the cellular membrane; but do not, as has been said, coagulate the fluids; for they do not reach the circulating system with their properties unchanged.

The *bitter* taste is confined to the oily and resinous juices of vegetables, and to the inflammable oxides. It is communicated to all vegetable substances by what is styled by the French chemists their combustion, in consequence of their union with nitric acid. Many of the vitriolated neutrals are also bitter; but in detailing their properties we must confine ourselves to the bitter vegetables; for there is no reason to suppose that our artificial bitters agree with the natural. We find the pure bitter chiefly in the roots of the gentian, the male fern, and the white dittany; in the bark of the simarouba, the orange and the lemon peel; in the leaves and flowers of the carduus benedictus and the camomile; in the wood of the quassia; in the tops of the centaury and hop; in the seeds of the carduus benedictus and maria; in the juice of the wild cucumber; in the aloes, the myrrh, and the bile of animals. It is seldom pure, and even in some we have mentioned it is joined with a little acrimony; in others with astringency, or acidity. The affinity of the acid with the bitter principle is very striking, since many plants which in some parts are bitter, in others are acid. We need not add any thing to what we have already said in the article *AMARA*, q. v. except to observe, that some of these mentioned are actively purgative, a quality which certainly does not belong to the pure bitter.

The *viscid* taste is exemplified in the mallows, lintseed, and almost all the pure gums, the cartilages and tendons of animals, particularly young animals. All these substances are demulcent and relaxant; consequently by sheathing abraded membranes, particularly of the urinary system and bowels, they relieve pain, and often appear to check immoderate discharges. They sometimes appear, when taken in excess, to destroy the appetite; and we have suspected them, when swallowed in large quantities, of lessening the urinary discharge.

The *salt* taste is most pure in the muriated soda and the common culinary salt, for all others appear to join different flavours with it. In the vegetable kingdom, we find it, though less pure, in the crithmum, the halimus and salicornia. In the shell fish and the fuci, the taste appears to be derived exclusively from the sea water. See *MARINUS SAL*.

The *watery* taste chiefly arises from the excess of the aqueous fluid, diluting every peculiar flavour. The most striking instances are the oleracæ, and some of the etiolated plants; and among the roots, the turnip. These substances are slightly nutritious, diluent, and demulcent. They were supposed to be of considerable and extensive use when diseases were attributed to lensor or viscosity of the fluids.

The sensation of *dryness* in the mouth arises very

generally from styplicity; but by a dry taste is generally meant that which is produced for instance, by chalk. All the earths in a carbonated state are dry. The insipid woods and barks, the leaves of the ivy, and the dust of the polypodium, are examples, in the vegetable kingdom. In the animal, the hart's horn, the crab's claws, the mother of pearl, and coral, are distinguished by a dry taste. These substances, however, unless capable of absorbing acids, are of little utility in medicine, but are by no means so injurious as have been supposed.

In general, we may remark that tastes have a much more pointed and clear connection with the medicinal properties of bodies than smells, and will, in many instances, explain, *a priori*, their virtues. Yet tastes are so infinitely varied by nature, that their composition cannot often be ascertained; and though the expressive language of Bergius conveys ideas peculiarly discriminated and exact, even this, in many instances, fails.

A very important distinction of tastes relates to their fugacity or permanence, their immediate impression, or their perception after some interval, their affecting the tip, the middle or back part of the tongue, or the throat. On these subjects our chief assistance is from Grew and Bergius; but we have not been able to connect these different sensations with the properties of the bodies. In general, the stimulants are immediately perceived to increase the heat chiefly on the fore part of the tongue; the narcotics only act after some time, and on the throat. The impressions of salt substances are generally diffused; of styptics confined to the cheeks and anterior fauces.

When the operations of chemistry attracted the attention of physicians, it was at once supposed that they would unravel every secret of nature, and among the rest, the constituent parts of medicines, so as to explain their operation. The members of the French academy laboured very earnestly in this department of the materia medica: Mr. Boyle and some others of the English and German chemists were equally assiduous; but they soon found, that aliments and medicines, the most salutary foods and the rankest poisons, were equally resolvable into acids, oils, and salts, scarcely differing in their properties. In fact, in resolving the compounds of nature, they formed new ones of art, and were not nearer the destined goal. Neumann and Cartheuser did not wholly forsake the former path, but they interrogated nature by milder methods, and extracting different component parts by the peculiar affinities of water and alcohol, or by their volatility in a gentle heat, taught us what portions of gum, resin, and oil each vegetable contained. But even at a much later period, so rash was the analysis, and so powerful the means employed, that we have only of late discovered what is now styled the extractive matter, or that portion of the gum and resin combined with the peculiar oil and mucilage of the plant, which renders it equivalent to the vegetable itself, deprived only of its air, some portion probably of its water, and the woody fibres. When, therefore, in the vegetable analysis, the proportion of gum and resin with that of the extractive matter is mentioned, the quantity of the two former, or rather of the resin, shows the degree of decomposition which in general has taken place; we say in general, for in many plants, particularly in

the roots, the resin exists in a separate state. Rhubarb is a striking instance of this kind.

Analysis, conducted with care, leads us, however, to form some conjecture of the nature of the vegetable. The expressed juices of the green and watery plants (the oleraceæ) are slightly laxative and cooling; in the language of the Boerhaavians, aperient; of the cruciform plants (the tetradyneæ of Linnæus,) antiscorbutic. Bitter extracts are tonic, often anthelmintic; oils and mucilages demulcent; essential oils generally stimulant and carminative; and resins either purgative or diuretic. Whatever opinion, however, be formed of the advantages of analysis in investigating the nature of plants, it has certainly assisted the pharmaceutical treatment of vegetable remedies, and, in the animal kingdom, has been of the greatest utility in showing the fallacy of many boasted remedies, from the identity of their nature, or their insolubility. Even musk and castor we find nearly approaching in their nature to resins, and the gluten of vegetables to animal substances. In the mineral kingdom, our obligations to chemistry are too numerous for repetition, and too obvious to detain us. We shall only remark, among these, the antidotes discovered to some of the most active poisons, and the advantages we derive from our power of preparing artificial mineral waters.

The utility of NATURAL HISTORY in investigating the properties of medicines is very considerable. To be able to ascertain with certainty the identity of any plant is an object of no little importance, as it prevents our disappointment in future trials. Were it not for the assistance of natural history, the greater part of the experience of the ancients would have been useless; and were it not for the aid of Caspar Bauhine, we should wander through their works, like the first travellers in the American forests. All around would be unknown: we could neither appreciate their views, nor follow their examples; yet we have known commentators on the ancient authors, who, supposing they meant some given medicine, were little anxious what it might be. A deep knowledge of botany, however, is unnecessary. We now know more than 50,000 species, and of these scarcely a hundred are employed in general practice; and of the latter, two-thirds, or even a greater proportion, are useless. Yet the principles of the science should be known, for the reasons just mentioned; and, above all, the foundation of the natural orders for the reasons and purposes already assigned. (See BOTANY.) One great advantage is, that if a given plant cannot be procured, a similar one may be selected from its natural order; and the author of the little tract on botanical analogy has shown, in a variety of entertaining examples, how the same remedy has been extolled and forgotten; repeatedly, at different periods, and under different names, revived.

OBSERVATION and EXPERIENCE are, on the whole, the safest guides; but here again we are lost in wildernesses or fogs. Numerous remedies, recommended as certain, are found to fail: what we have ourselves, at different times, considered to be firmly established as proofs of holy writ, at others we have found less substantial than the shadow of a shade. In every step we feel the truth of the Hippocratic axiom "experientia fallax." If those whose education and experience con-

tribute to point out the danger of deception, find that the *post hoc* is not always equivalent to the *propter hoc*, how many sources of deception must surround those not accustomed to such observations? Yet medicines are commended by men of the first character, rank, and abilities, as certain remedies; every newspaper teems with affidavits, and we are deemed incredulous indeed if we disbelieve a bishop or a judge. Medical evidence differs greatly from every other: we are obliged to act on the result of reasoning often extremely insufficient; our decisions on the effects of medicines, on the contrary, require the most rigorous examination. If a man asserts, for instance, that he has been cured of a consumption by Godbold's syrup, it implies several positions extremely doubtful. How can he ascertain that the disease was a consumption? for in this respect the most judicious practitioner is often deceived. But, admitting that it is so, we know that vomicæ are often completely discharged: we know that an ulcer spontaneously heals, and it is as probable that diet and regimen may have effected the cure, as a medicine equally inconsiderable in its powers. If then we cannot trust to experience, what must be our resource? Though nothing may be certain in the operation of medicines, and our evidence only establish different degrees of probability, yet a rigorous scrutiny in the investigation of every fact respecting this part of the science will greatly facilitate our progress in similar circumstances. Authors on the materia medica abound with assertions respecting the properties and use of every medicine, and the most inert is often represented in colours too glaring for even the most active. This partly arises from the want of discrimination just mentioned, but more often from an anxiety to display the extent of their own learning; and such are the accumulated recommendations which the student finds, that he thinks his only labour a selection. So frequent are his disappointments, that he at last mistrusts even the most respectable authorities. Who will cleanse this Augæan stable? It will require an Herculean hand; and the little that can be done in a general work like this can scarcely lessen the labour. We shall not, however, mispend our time, if we examine shortly the conduct of the best authors on this subject.

In this enumeration we should have omitted the systems of the astrologers and the signaturists, but that the fancies of the latter still remain. The former we may safely neglect, though not wholly forgotten by the empirical old women of the country, who still prefer collecting plants at the full or new moon. The signaturist prefers plants which resemble the part diseased; and euphrasia is still used for complaints of the eyes, though its original claim to notice arose from a black spot in its corolla resembling the pupil; and the pulmonaria is employed in diseases of the lungs, because its form, its texture, and its spotted areolæ, afford a distant resemblance to these organs. Crolius is the great authority of this sect: but to return to more rational authors.

The earliest therapeutical authors were the natural historians; for to their descriptions of plants were usually added their medical virtues. The herbals, as they may be called, from the time of Theophrastus and Dioscorides to Gerarde, &c. are full of extravagant commendations of the most inert vegetables. The latter authors were indeed compilers only; and, if they added

to the bulk of their volumes, were little anxious about their value. They are, in general, careful to tell us in what degree a medicine is hot or cold, to what temperament it is best adapted: but to distinguish the diseases, or the periods of any disease in which a given plant would be most salutary, was often beyond their powers.

When botany assumed a more scientific aspect, and distinction as well as description was its object, our knowledge of the materia medica was greatly assisted. The herbalists had accumulated their commendations with little discrimination; but in the materia medica of Linnæus we find more accuracy. He first published that of the vegetable kingdom, and afterwards in the *Amœnitates Academicæ* those of the animal and mineral. In each he followed his own system. These treatises were republished by Schreber at Vienna, in 1773, with additions from the *Amœnitates* and the later works of the northern naturalist. In this volume we are told whether a medicine is common, rare, or useless; and, in enumerating the qualities, which are those of the greatest importance, the author points out often, by distinguishing marks, how far the boasted powers may be depended on. Tessari, in his republications of Linnæus's system at Venice under the title of *Materia Medica Contracta*, has carried this plan farther; and in a MS. which was some years since intended for publication, it is still farther extended and more complete. Bergius, an author of the Linnæan school, has described plants according to his master's system, and, in the most precise and pointed language, conveys very accurate ideas of the sensible qualities of every vegetable remedy. Of the qualities he only mentions the most important; and the practical observations, almost exclusively his own, are few, though important. He apologizes for not copying former authors by observing, "that those who have examined them will soon discover that so many fictions are interspersed with what is true, that they cannot be easily separated. Many writers on the materia medica, he adds, "have injured this science by trifling fictions and conjectures; by inventing qualities dictated by their prejudices, which they have obtruded on nature. Some have compiled from former authors, inserting their own opinions and their own observations. Many, with too much credulity, have adopted and transcribed the assertions of their predecessors, though of doubtful authority and sometimes ridiculous; so that, in more recent authors, we find the old remnants repeatedly hashed; blunders again and again copied." We add the words of Bergius partly as an apology for ourselves, since from the pages of Motherby we have been obliged to expunge qualities of medicines far more numerous than those which the experience of others, or our own, has justified us in retaining. The pharmaceutical and miscellaneous remarks of Bergius are highly valuable; and we regret that the animal and mineral kingdom had not equally shared his attention.

HALLER, in his description of the plants of Switzerland, has followed, in the arrangement, his own botanical system. As usual, he has annexed to each plant its medical virtues; and this portion of the work has been republished by Vicat in two small volumes. Haller seldom indeed speaks from himself; for he was not a practical physician, and his compilation is not very discriminated. The best part of his work relates to the

domestic medicine of the Swiss mountaineers. Dr. WOODVILLE's *Medical Botany* is of this class; but in his three volumes he only considers the vegetables included in the lists of the London and Edinburgh colleges. In the fourth, some of the plants used in medicine, not included in these catalogues, are figured and described. The substance of this work is chiefly taken from the *materia medica* of Lewis and Cullen; but the plates, which are indeed elegant and accurate, are equally beautiful, and far more numerous in the large and expensive folio of Plenck. RAY, in his history of plants, adds their medical virtues; but Ray, like Haller, was no practitioner; and the greatest abilities, the soundest judgment, will not teach that nice medical discrimination, without which compilations are useless. Yet Ray's collections are so extensive, that he merits all the attention, which is not inconsiderable, that he has received. Some other authors have treated of the *materia medica* as general botanists. The *pharmacologia* of our own Dale is obsolete, yet it displays judgment and discrimination; for he has avoided the common error of his predecessors, that of collecting every idle observation from the works of his predecessors. Simon Paulli's *Quadripartitum, Botanicum*, connected, however, but slightly with the botanists, is deservedly neglected; and Zorn's *Botanologia Medica*, in the German language, scarcely merits more attention.

It is not from forgetfulness that we have omitted noticing MURRAY's *Apparatus Medicaminum*, in six volumes of unequal bulk. We have separated this work from the rest, because it affords the first example of arranging vegetable medicines from their natural orders. We have already spoken of his merit in this respect; and must now add, that he has collected with great care what the best practitioners who preceded him had taught, and has probably left little for his successors but the labour of discrimination. This part of the task he has greatly neglected; and his work is, on this account, by far less valuable than it might have been. His collection, however, is by no means like that of Vogel, indiscriminate. Gmelin has published the *materia medica* of the mineral kingdom as a Supplement to Murray's Apparatus, but with still less discrimination, and with very few marks of a correct judgment.

Many authors on this subject have followed a more arbitrary arrangement, though in part botanical. Thus, Simon Paulli has divided his plants as they flourish in either of the four seasons; Vogel, according as the leaves, bark, wood, or roots are employed, again subdivided as frequently or seldom employed, or as obsolete, arranging them afterwards alphabetically. The subject is thus broken into so many detached parts, that from the laboured order the greatest confusion arises. Vogel is also a most laborious collector, with little discrimination; and though a judicious practitioner, seems in this work to have forgotten himself, and to have become a compiler only. It is, however, a manual little inferior in extent of compilation, though of comparatively little bulk, to that of Murray. Another collector who follows, in part, a botanical arrangement, but who does not display a superior discrimination, is Dr. Alston. His chief value arises from his copious compilations from the Greek and Roman authors; but his materials are so inartificially and unpleasingly compacted, that we suspect that he has been seldom read.

HERMAN, in his *cynosura* of the *materia medica*, has united the botanical and chemical authors. He arranges his vegetable remedies from the parts employed, and subdivides them according to their chemical analysis. His work is little known in this country, and as a compilation from almost forgotten German authors deservedly neglected. GEOFFROY, who follows a botanical arrangement, has been also peculiarly attentive to chemical analysis; and his *Materia Medica* is equalled by few works on the subject in extent of information or judicious discrimination. It is unfortunately little known, though meriting from the student minute attention; and there are few veterans in practice who might not consult it with advantage. The Supplement, containing the account of animals by Nobleville and his coadjutors, is of very inferior merit. Neumann, in his chemical works, gives us some very judicious and minute analysis of vegetable remedies; but the system of *materia medica* which rests chiefly as the foundation of its arrangement on the chemical contents of medicines, is that of CARTHEUSER, which, on this account, merits particular regard, and is, in some other views, a valuable and judicious work.

If these systems are arbitrary in their arrangement, and, with the exception of the apparatus medicaminum giving little assistance to the student, and scarcely illustrating the use of any medicine, by the observations that may have been offered on the preceding or following article, still less advantageous must be the alphabetical order which Lewis has followed in a most admirable work, and Dr. Rutty, in a very inferior one, on the *materia medica*; an arrangement, if it can be styled one, which Vogel, Geoffroy, and Herman, have in a great degree adopted. The therapeutical writers on the *materia medica* have followed a very different path. Considering medicines as producing certain specific changes in the body, those which produce given changes are arranged under the different and appropriate heads. We thus find not only the principles on which they act, but are able, with very little inconvenience, to compare in given circumstances the advantages and disadvantages of each, or when disappointed in the effects of one, to supply its place with another. In this way also the individuals of each class form one separate distinct subject, scarcely, if at all, broken by a consideration of the different qualities of each. In the arbitrary alphabetical arrangement, which, from the nature of this work we are compelled to adopt, we can scarcely avail ourselves of the advantages just stated. We have endeavoured, however, to combine this plan by enlarging the therapeutical articles, and interweaving, in these, the foundation of our choice of individuals, in different circumstances.

It will be obvious, that in pursuing a plan of this kind, authors must differ according to their different objects. Thus SPIELMAN, who connects the chemical and therapeutical sects, scarcely employs indications but as the titles of his chapters; while Dr. CULLEN, diffuse on the therapeia, is short and often unsatisfactory in the history of many individuals. In short, this latter work, though vast, bold and comprehensive in its design, is, however, as it has been styled by an able critic, rather the philosophy of the *materia medica* than a detail of the nature and properties of medicines. CRANTZ' work is short and unsatisfactory in a therapeutical view, though judicious

and able in the remarks on different medicines; while JUNKER, and DE GORTER, offer little but a catalogue of medicines arranged according to indications. The latter, though published as that of David, was really the work of his father, John De Gorter, one of the most judicious and intelligent commentators on the aphorisms of Hippocrates. The choice of the plans of teaching the *materia medica* must lie between the arrangement of medicines according to their natural orders, or according to their therapeutical qualities. The botanical affinities in the Linnæan orders are not, however, so strictly medical as to render this plan very eligible, and though the arrangement is improved by Murray, it is far from being sufficiently accurate for this purpose. The natural orders of Jussieu, as more numerous, are more natural in a botanical view, but are consequently less usefully therapeutical. The therapeutical plan is, therefore, undoubtedly preferable, and, with it, the former may be more intimately united than by Dr. Cullen, for he has not introduced all the natural orders of Linnæus, though he has grouped some vegetables, in orders strictly natural, not found in the fragments. The orders are not so numerous as to require what Linnæus calls a method, or a *clavis*, to connect them; yet their arrangement is by no means to be neglected, as the therapeutical observations necessary to introduce each are intimately connected. Dr. Lewis has proposed an arrangement of the *materia medica* into eleven natural orders, which are not formed exclusively from the properties or the effects. These are acids, absorbent earths, insoluble earths, glutens, oils, astringents, sweets, acrids, aromatics, bitters, and emetics, including cathartics. These orders certainly afford no eligible system of arrangement. Some minuter groups retained in the foreign pharmacopœia, as the *four cold seeds*, &c. we shall notice under PHARMACIA.

In Dr. Cullen's system the *materia medica* is divided into nutrients and medicines: nutrients are food and drink, with which condiments are joined.

Medicines either act I. on the solids, or II. fluids. The first act either on the simple or the vital solid. Medicines which act on the simple solid are *astringentia*, *tonica*, *emollientia*, and *erodentia*. Those which act on the vital solid are *stimulantia*, *sedativa*, including *narcotica*, *refrigerantia*, and *antispasmodica*.

Those which act on the fluids are such as either produce a change, or occasion some evacuation. The changes respect the fluidity, comprising *attenuantia* and *inspissantia*, or the mixture: when they correct general acrimony, they are styled *demulcentia*; when particular acrimony, *antacida*, *antalkalina*, and *antiseptica*. The medicines which occasion evacuations are *errhina*, *sialagogica*, *expectorantia*, *emetica*, *cathartica*, *diuretica*, *diaphoretica*, and *menagoga*.

In this arrangement Dr. Cullen has forsaken his own system of pathology, since the fluids, in his opinion, are not affected, without previously influencing the moving powers. Some other critical remarks might be added, were this the place for such disquisitions. To connect this part of the work with what has preceded, and will follow, we shall add what appears to us a more convenient arrangement, and subjoin a list of the *materia medica* adapted to it, adding the pharmaceutical or Linnæan names, while the more particular references may be found under each article.

It has been usual in these circumstances, with Spielman and Cullen, to premise the nutrientia; but as this would only extend the clavis, and we have already treated of it at some length under ALIMENT, q. v. we shall now omit this class, which consists only of FOOD, DRINK, and CONDIMENT.

ANTHELMINTICA.

The classes of the materia medica are not so numerous as to require what is usually styled a methodus; and, if any thing were sacrificed to the parade of system by this means, it would be improperly adopted. Whatever may be its merits, it has no disadvantages, for the arrangement is exactly such as if the orders were natural and independent; and the clavis limits the intention of the group with peculiar accuracy. The evacuants most nearly related follow each other; and as no evacuation can take place without the excitement of the vessels as muscular organs, so in the following class, stimulantia, where the nervous system is more generally affected, a general action of the vessels of the whole system usually accompanies. Of the synonyms of Stimulantia the two first, should such medicines exist, act more peculiarly on the nervous system: the two last are topical remedies. The distinction between general and topical medicines usually admitted is, at best, useless, if not injurious; for the most active internal medicines, are often powerful topics.

The next division is also connected with some action on the sanguiferous system, which disappears in the second class, the antispasmodics. Resolvents are truly refrigerants, for discutients occur in a subsequent part. The medicines which increase tone are included under tonica, and the astringents are referred to those medicines which act on the simple solid. Some certainly act on both, and astringents, as already explained, (see ASTRINGENTIA,) sometimes appear to be tonics. The medicines which diminish tone, diminish also sensibility and excitability; and we have added as synonyms anodyna and inirritantia; those which possess an opposite quality are commonly associated in idea with stimulants.

We have admitted, with limitation and reluctance, any action of medicines on the fluids, adopting the axiom of the nervous pathologists, that the constitution forms its own fluids. Yet some complaisance is due to many excellent physicians of the Boerhaavian school, and it is at least necessary to point out the medicines which have been employed with these views. The third of the classes of the first division, the alterantia, is vague; yet the action of remedies in scurvy, in what are styled scorbutic eruptions, in lepra, and some other cases, must be collected into one group, and it is not easy to find a more proper place. In the second division we clearly perceive the action of demulcents on the throat, the stomach and alimentary canal, the urinary organs, and perhaps the bronchial glands. The antacids and antalkalines are at least useful in the stomach, and some medicines undoubtedly act, chemically, as antiseptics.

The medicines which act on the simple solids afford few subjects of remark. If relaxants are any thing more than emollients, they bear the same reference to the sedantia that the astringents do to the tonics; at least they seem to act through the medium of the simple solid. For these and the other reasons assigned, the astringents are referred to this place. The last general division contain classes independent in their operation on each other. Lithontriptics may be only antacids,

but they are said, with confidence, to dissolve the calculus. Anthelmintics may be only drastic purgatives, but some at least kill worms. The observations on the subdivisions of the catalogue must be deferred till that is concluded.

It is a common objection to any arrangement, that some medicines possess very different powers, and that their proper places are not easily ascertained. Instances of this kind occur in mercury and steel. Repetition, however, is unavoidable; and those who seek for the medicine appropriated to any disease in such catalogues, must find them in each list. The more general author on the materia medica, will treat of them under that head where their powers are most conspicuous; and the medicine will again recur, where, from its preparation, or exhibition, peculiar properties are discovered in it. The catalogue, which we shall add, will differ from former ones by the subdivision into groups, which may be styled orders, an attempt first made by Dr. Duncan in his Therapeutics. The plan we have followed is adapted to the therapeutical ideas offered under the different articles; and we consider this mode of arrangement as peculiarly useful at least to the student, since it offers at almost one view a more distinct idea of the

powers and properties of each medicine than is obtained in the best systems. The catalogue itself can possess no other very peculiar advantages; yet we cannot conclude this part of the subject without acknowledging our obligations to the very excellent syllabus of Dr. George Pearson, who lectures on the materia medica with distinguished, and if we can judge from this little work, with the most merited reputation.

In our general observations on the materia medica, we mentioned the plan of some authors, and particularly of Tessari, of distinguishing the degree of power by slight marks at the end. This idea we have occasionally pursued; and while we have followed, without any very nice discrimination, the conduct of our predecessors in the medicines inserted under each class, when their powers are considerable we have added a note of admiration (!); when dangerous two (!!); when trifling, a semicolon (;); when doubtful, a note of interrogation (?); when the medicine has been introduced by fancy, folly, superstition or prejudice, a colon (:). These marks are only added to a few, and for the Linnæan appellations and synonyms the reader is referred to the separate articles.

From such an arrangement of the *materia medica*, and this subdivision of the classes, the young student, or the more discriminating inquirer, will, we think, find his labour greatly facilitated, as he will not be obliged to range through a muster roll of names to attain the object of his search. It remains only to explain the foundation of these subdivisions.

EMETICS, though a class far from numerous, and of simple operation, yet require some distinctions. We do not always require full vomiting, and we sometimes want this action to produce a very sudden and violent change. It may be supposed that all emetics, in a less dose, will nauseate, or in a more active one give a sudden and violent shock; but *ippecacuanha* seldom produces sickness without vomiting, and squills will very seldom occasion a complete action of the stomach. *Ipecacuanha* also acts with no more violence in a large than a small dose, and *mercurius vitriolatus* is severe in its operation even in a small one.

Of CATHARTICS and the foundation of the distinctions we have already spoken; and these lead us to remark another advantage of the subdivisions, a more ready reference to the proper remedies in other parts of the catalogue. Drastic purgatives would be injurious as diuretics in nephritis, and mild ones very inefficient as anthelmintics.

There is certainly a very striking, and, in a practical view, a very important, distinction between the relaxant and the stimulant DIAPHORETICS. If we have been right in our views under this article, the *diaphnoica* equally merit a selection. A view of the remedies included in the list will, at least, show the propriety of the distinction. It appeared, indeed, so strong, that in the first sketch of this article, made for a very different purpose, twenty-five years since, the alterantia were included in this class.

The stimulant, the diluent, and the narcotic DIURETICS are equally distinguishable. Perhaps the *salina* are not properly arranged with the stimulantia; but we were determined by the fact, that nitre, and some of the other neutrals, in large doses, produce pain in making water. They are, however, distinguished; the strontia and barytes are inserted with doubt and hesitation.

The division of the extensive and doubtful class of EXPECTORANTS is made from the nature of the medicines recommended. The first, however, act chiefly on the fauces; the second and third on the fever, except where employed in the form of gas or vesicular vapour. The fourth contains only the real expectorants; and of the whole subdivision there are few strictly such. Some of these are slightly astringent, and should have been separated to have marked them as frequently injurious, or at least only useful in a relaxed state of the glands. Of these the agrimony marked with a note of interrogation is the most hurtful; but the whole of the group must be used with caution when inflammation exists.

Dr. Cullen used to distinguish the ERRHINES according to their effects as irritants and evacuants; but we found it difficult to follow the idea on an extensive scale; and the whole, at last, seemed resolvable into their less or greater acrimony. At least this distinction is abundantly sufficient to assist our practice.

The division of SIALAGOGUES is sufficiently obvious.

There is but one certain internal remedy of this kind, mercury. Yet, from the late experiments with the nitric acid in syphilis, there is some reason to suspect that it may have a similar power. The experience of others, however, has scarcely supported the suspicion, and it is consequently inserted with the mark of doubt. In the other list, though almost all the stimulants might have been inserted, those usually preferred are only enumerated.

In the class of EMMENAGOGUES it was necessary to distinguish those which stimulate the system in general, from those whose irritation is confined to the uterus, or whose action is of a different kind. The two first orders contain the general and topical stimulants: the two next the antispasmodics and tonics. All the medicines included in this class are employed, and the distinction will be amply explained under the article MENSES.

The STIMULANTIA have occasioned no little difficulty in the arrangements. The diffusibilia and the topica are chiefly distinguished in the Brunonian works; but as we have rejected the principles, we cannot be expected to adopt their consequences. We could not, however, wholly avoid them. Some stimulants are very general in their action, others confined to particular parts. Yet they pass into each other by such imperceptible shades, that we found it difficult to draw the line, and have passed with sufficient accuracy from the more general to the more partial stimulants. The *topica* are those chiefly of topical application. The insertion of the order *indirecta* appears to lean to the Brunonian doctrines, and we have explained their action to be of a sedative nature, producing an unequal excitement, and, in consequence, an apparent stimulus. Yet a work of this kind must not only contain the author's own opinions, but those of others: above all, it is necessary to point out that some of these medicines are employed with success as active stimulants.

The REFRIGERANTIA are few and simple. The ANTISPASMODICA, as not connected with general effects, ought perhaps not to have been admitted as a class; but some complaisance is due to former authors, and the first subdivision cannot be referred to any general power. The subdivisions which follow sufficiently show that the power of destroying spasm very commonly depends on its cause.

TONICS are also with difficulty distinguished in their several subdivisions. The natural arrangement is into bitters joined with astringency, pure bitters, and the more pure astringents. Yet it is not easy in the practice, and we have preferred uniting the warm with the purer bitters, and distinguishing them from the narcotic bitters, for reasons which will be obvious on perusing the article AMARA. The subdivision *fossilia* requires an apology, since it does not point out their peculiar properties; but we could find no suitable appellation, as they have no sensible operation. The more pure astringents follow, which are also tonics.

The SEDANTIA are the *refrigerantia* or *narcotica*, and this division requires no remark. The ATTENUANTIA are merely diluents, or such medicines as enable the serosity to dissolve a larger proportion of the gluten. The *dulcia* are added on the authority of Dr. Stark, who confined himself to a saccharine diet, and, after some time, experienced all the symptoms of sea scurvy. Yet

these experiments must be admitted with hesitation, as his constitution, from a series of wanton trials, was previously much debilitated. *Diaeta insalubris*, more strictly unalimentary, is founded on the instances which have occurred of the symptoms of scurvy from such diet; but it is not likely to be employed as a remedy.

The remedies included under the *INSPISSANTIA* show that it is highly improbable such a change could be produced by medicines. The remedies for scurvy and the tonics are the only probable means of correcting too great tenuity.

The *ALTERANTIA* contain, as already hinted, the *diaphoretica diaphnoica*; and the only other remedy which we were able to introduce is *diata*.

The subdivisions of the *DEMULCENTIA* and *ANTACIDA* are sufficiently obvious, and not very important, perhaps not chemically correct; but affected minuteness, or extreme accuracy, which would multiply trifling subdivisions, is certainly no improvement. The *ANTALKALINA* and *ANTISEPTICA* admit of no subdivisions; and those of the *EMOLLIENTIA* are sufficiently obvious.

The *ERODENTIA* are naturally divided into the *azotica*, which destroy the life of a part, and the *solventia*, which consume it. Many of the latter act as azoetics; a term borrowed from the excellent syllabus of Dr. G. Pearson: but it is necessary only to point out the medicines usually employed with either view.

The *ASTRINGENTIA* are chiefly external remedies; for the internal astringents are enumerated, as already explained, under tonics. The *ALEXITERIA*, the antidotes, are chiefly those enumerated by authors. The only novelty is the antidote of nitrous air, inserted in consequence of a case lately recorded, where death ensued from a person having copiously inhaled the fumes of nitrous acid from a bottle bursting. From the symptoms it appeared that the oxygen had been separated in the system, and the acid appeared in every excreted fluid. Alkalis, in the first instance copiously taken, would probably have succeeded; and the best form would have been that of soap. The *LITHONTRIPTICS* and *ANTHELMINTICS* are those usually enumerated. The last class is peculiarly full, as it has been supposed that we have few medicines of this kind, and of uncertain efficacy. The fact is, that diseases are often attributed to worms when none exist, or when they are not in the slightest degree injurious.

We have thus completed a catalogue of the *materia medica* on a new plan, more full and complete, we trust, than any yet communicated to the public in general. Its errors may be numerous; but they have not arisen from want of attention, of labour, or observation. Many large works have perhaps cost less pains than the compilation of these few pages.

Murray Apparatus Medicaminum; Gmelin's Continuation of Murray; Lewis, Cullen, Geoffroy, Linnæus, Bergius, Spicلمان, Vogel, and Cartheuser's *Materia Medica*; Duncan's New Edinburgh Dispensatory; Dr. G. Pearson's very extensive and valuable Syllabus.

MATERIA MERCURII SALIS. See *CIRCULATUM*.

MATERIA TURRA. *INTEMPERATURE*. Castellus.

MATHÆI PILULÆ. *MATHEW'S PILL*. Starkey was its author, but it was sold by Mathews for him as

an universal medicine. It consisted of the soap of tartar, black hellebore, opium, &c.

MATLOCK WATERS are found at the place from whence they take their name in the county of Derby, where there are a great number of warm springs, which, according to Dr. Short, acquire their heat by passing through a bed of lime, and what he calls *croil stone*. The water of the bath, and all the other tepid springs, is exceedingly clear, has no steam except in cold weather, and does not throw up bubbles: it is about a drachm in the pint lighter than common water.

A gallon of this water contains about thirty-seven or thirty-eight grains of solid matter, twelve or thirteen grains of which are sea salt, with vitriolated magnesia, the rest calcareous earth, which after calcination, contained some particles attracted by the loadstone. This water seems, therefore, to be a light chalybeate of a tepid temperature, containing but a small portion of solid matter, and is used in the diseases for which Bristol waters have been recommended; externally for the gout, rheumatism, and other complaints, where a tepid bath has been found serviceable. It is drunk from one to four or five pints in the day.

MATRA'CIUM. See *CURCUBITA*.

MA'TRES. The two membranes of the brain, the *PIA* and *DURA MATER*, supposed to be the origin of all the other membranes. (See *DURA MATER*.) In botany, the *artemisia* is the *mater herbarum*; in chemistry quicksilver is the *mater metallorum*.

MATRICA'LIA, (from *matrix*). Medicines appropriated to disorders of the uterus.

MATRICA'RIA; *parthenium*, *febrifuga*, *metricaria*, from *matrix*. COMMON FEVERFEW, FEATHERFEW, or *FEBRIFUGE*, *matricaria parthenium* Lin. Sp. Pl. 1255.

This plant hath firm branched stalks and roughish leaves, each of which is composed of two or three pairs of indented oval segments, set on a middle rib, with an odd one at the end, cut into three lobes; the flowers stand on the tops in the form of an umbel, consisting each of a number of short white petals set round a yellow disk, followed by small striated seeds. It is perennial, grows wild in hedges, in cultivated places, and flowers in June.

The leaves and flowers have a strong, not agreeable, smell, with a bitterish taste, both which they communicate to water and spirit. On distilling a large quantity of the herb, a yellowish strong scented essential oil is found on the surface of the water: rectified spirit carries off but little of its flavour in evaporation. The spirituous extract contains a large share of the virtues of the plant, which is esteemed as a warm aperient, carminative, and bitter. It resembles, in sensible qualities and botanical affinities, the camomile, and keeps its virtues for several years. Its oil is called *ol. partheniacum*. See Raii *Historia*; Lewis's *Materia Medica*; Neumann's *Chemical Works*.

MATRISY'LVIA. See *ASPERULA* and *CAPRIFOLIUM*.

MATRIX, (from *mater*, the mother). See *UTERUS*, and *MEDITULLIUM*.

MATURA'NTIA, (from *maturo*, to ripen). See *SUPPURANTIA*.

MAU. See *MANGA*.

MAUROMARSON. See *MARRUBIUM*.

MAXILLA, (from *μασσω*, to *chew*.) *mandibula*. THE CHEEK OR THE JAW. See BUCCÆ.

MAXILLA INFERIOR, *meta*. The LOWER JAW is situated at the lower part of the face; divided into the chin, sides, and processes. The chin is the anterior middle part; the sides are continued beyond the chin, till the bone, bending upwards, forms the processes. On the middle part of the chin externally there is a transverse ridge, on each side of which the quadrati, or depressores labii inferiores, and the elevatores labii inferiores, hollow out the bone, and are lodged in the furrow. On the internal part of the chin are three protuberances, to the uppermost of which the frænum linguæ is tied. From the middle protuberance the genioglossi arise; and from the lowest the genio hyoidei: below the last the digastric muscles are attached to two sinuosities; and at the lower and anterior external part of each side of the maxilla inferior there is a small protuberance, whence the depressor labiorum communis proceeds: and nearer the upper edge is a longitudinal ridge, where the buccinator is inserted; inwardly, towards the superior ridge of each side, is a ridge, whence the mylo hyoidei rise. The lower edge of the chin and sides are smooth, and are called the base of the lower jaw, the extremities of which are named the angles: the outer surface of these angles hath several inequalities where the masseter is inserted, and the inner surface where the pterygoideus internus is attached.

The anterior sharp process is called *coronoides apophysis maxillæ*, round which the temporal muscle is inserted; and the posterior process is called *condyloid*, which is received into the glenoid cavity of the os temporis. The upper part, where the teeth are inserted, is called the *alveolar process*.

The foramina are two on each side, one near the root of the processus internally, where a branch of the fifth pair of nerves with an artery and a vein enters; the other, external, at the edge of the chin, where the nerve and the vessels come out.

MAXILLA SUPERIOR, the UPPER JAW, is composed of thirteen bones, viz. the ossa nasi, unguis, malarum, maxillaria, palati, spongiosa inferiora, or turbinata inferiori, and the vomer.

The diseases of the maxilla are chiefly those of the sinuses, and in these worms have been sometimes found; but they are more commonly receptacles of purulent matter. They are sometimes the seat of fistulous ulcers, occasionally of a destructive fungous or cancer, and often of a caries, which happens in some instances after measles or small pox. Matter is let out by drawing the first or second molar tooth, and we recollect, among Gooch's cases, one in which it was discharged by puncturing the cheek. In the *Ephemerides Naturæ Curiosorum* is an instance of a total separation of the lower jaw which the man survived. See LUXATIO and FRACTURA.

MAXILLARÉS SINUS, (from *maxilla*, the *jaw*.) THE MAXILLARY SINUSES are lined with a glandular membrane, which secretes a mucilage very different from that of the joints.

MAXILLARÉS GLANDULÆ. THE MAXILLARY GLANDS. Each is placed between the angle of the lower jaw and the os hyoides, and fills up the space between the belly of the digastric muscle and the pterygoideus internus at the angle of the jaw. The anterior edge lies over the muscle called *mylo hyoidæus*, from whence arises

its duct, running close under the membrane of the mouth, and by the side of the sublingual. Each opens at an angle, close by the frænum of the tongue, just behind the incisores. The duct runs from its upper anterior part, on the outside of the genioglossi, and the inside of the sublingual, and opens near the frænum linguæ.

MAXILLA'RIA SUPERIO'RA OSSA. These form the greatest part of the upper jaw. That long process, which, rising from its superior and anterior part, grows smaller as it proceeds upwards, to make the side of the nose, is called the nasal process. The alveolar process is that spongy part where the sockets for the teeth are formed. The palatine process forms a great part of the basis of the nostrils, and the roof of the mouth. The orbiter process is very irregular: from its superior and anterior part, to near the extremity of the nasal process, a ridge proceeds which forms about one third of the outward circumference of the orbit. The bodies of the superior maxillary bones are entirely hollow, and in each is a large sinus, called ANTRUM HIGHMORIANUM, q. v.

MAXILLA'RIÆ ARTERIÆ. THE MAXILLARY ARTERIES. The external artery, also called the genial and angular artery, is a branch from the external carotid. It runs to the basis of the lower jaw, close to the attachment of the masseter, and gives a branch to the maxillary gland. Passing over the lower jaw, it goes upon the buccinator, gives a branch to the lower lip, which anastomoses with that on the other side, and is continued to the upper lip, where it also anastomoses: there they are called labial arteries. The external maxillary then gives off branches to the nose, goes to the inner canthus of the eye, is lost upon the forehead, communicating, in that part, with the temporal artery.

The internal maxillary artery is a branch from the external carotid, rising at the origin of the temporal, and distributed to both the jaws: it is very much convoluted, and gives branches to the deep seated parts; one branch runs through the lower jaw, called the inferior maxillary artery; but the main trunk runs up to the foramen lacerum inferius, at the bottom of the orbit, winds round the antrum, and sinks into the nose behind the upper maxillary bone, and before the pterygoid process of the os sphenoides, to be lost on the inside of the nose.

MAXILLA'RIS INFERIOR NERVUS, *ramus inferior*, is the third branch of the fifth pair of nerves. It passes through the foramen ovale of the os sphenoides, where it gives off several branches to the muscles of the lower jaw, then throws a remarkable branch through the lower jaw to supply the teeth; which comes out at the anterior part of the channel, and branches upon the lip. From this a capital branch is detached to the tongue, called the lingual, which runs between the two pterygoid muscles, and passes to the top of the tongue, going with the duct of the maxillary gland. From this the chorda tympani is derived. See TRIGEMINI.

MAXILLA'RIS SUPERIOR NERVUS. THE UPPER MAXILLARY NERVE is the second branch of the fifth pair. It passes through the foramen rotundum of the os sphenoides, where it throws off a branch to the palate; but the trunk passes on in the sulcus of the upper

maxillary bone, goes to the upper jaw, and to its antrum. It then comes out below the orbit, and is diffused upon the face, particularly upon the nose, the upper lip, and cheek. See TRIGEMINI.

MAYS is a kind of Indian wheat. See CEREALIA.

MEA'TUS, (from *meo, to pass,*) a DUCT, PASSAGE, or any open canal. The auditory passage is the *meatus auditorius*; the Eustachian tube *meatus à palato ad aurem*; the urethra *meatus urinarius*; the ducts which convey the bile from the gall bladder to the duodenum the *meatus cystici*.

MEA'TUS AUDITO'RIOUS EXTE'RNUS is the external passage to the ear, beginning at the hollow of the outer ear, and ending at the drum. It was formerly a name for the Eustachian tube. See AURICULA.

MEA'TUS CÆ'CUS. See TUBA EUSTACHIANA.

MECAPA'TLI. The American name for one of the species of sarsaparilla.

ME'CCHA, BALS. See BALSAMUM.

MECHOACA'NA A'LBA, (from *Mechoacan*, a province in Mexico, whence it was brought). *Rhabarbarum album, convolvulus Americanus, jalapa alba, bryenia alba Peruviana, mechoacan*. It is the root of an American species of convolvulus, chiefly brought from a province in Mexico; but its flower has not been so accurately described as to enable us to ascertain strictly to what genus it belongs. In the later works of Linnæus it has been referred to the genus convolvulus, with the trivial name of *mechoacana*, but with no peculiar precision. It is cut into thin transverse slices, like jalap; but is larger, whiter, and softer. This root was first brought into Europe in 1524, as a mild cathartic, which, having but little taste or smell, was thought not to offend the stomach; but the common jalap hath superseded its use. The *phytolacca decandria* Lin. Sp. Pl. 630, furnishes the *Canadian mechoacana*. See Raii Historia; Tournefort's *Materia Medica*.

MECHOAC'ANA NI'GRA. A name of the jalap in common use. (See JALAPA.) The Brasilians call it *jetecucu*.

ME'CON, (from *μικρος, bulk*; from the largeness of its head). See PAPAVER.

MECO'NIS and MECO'NIUM, (from *μικρον, the poppy*). See PEPLION.

MECO'NIO, (Syr. c.) (from the same). See PAPAVER ALBUM.

MECO'NIUM, (from the same). Opium is the juice flowing from the poppy head through artificial incisions; but meconium is the juice of the whole plant, first bruised, then pressed out. The excrement also contained in the intestines of a newly born infant, which has obtained its name from its resemblance to opium. See INFANS.

MEDE'NA. A species of ulcer. Paracelsus.

MEDE'NA VE'NA; the same with *medinensis vena*. Castellus.

MEDIA'NA VE'NA, (from *medius, middle*). A remarkable vein on the inside of the flexure of the cubit, between the cephalic and basilic veins, called by the Arabians *funis brachii*. It is frequently opened in bleeding.

MEDIA'NA CEPHA'LICA, (from the same). See CEPHALICA MEDIANA.

MEDIA'NUM, (from the same). See MEDIAS-TINUM.

MEDIA'NUS, (from the same). See CERVI-CALES.

MEDIASTI'NA, (from the same). See INFLAMMATIO MEDIASTINI.

MEDIASTI'NÆ ARTE'RIÆ, (from the same). The arteries of the mediastinum arise from the subclavian, and arc spread on the mediastinum.

MEDIASTI'NÆ VE'NÆ, (from the same). The right vein of the mediastinum comes out from the trunk of the superior vena cava anterior, a little above the azygos; the left from the subclavia.

MEDIASTI'NUM, (from the same,) *medianum*, is the membrane called the pleura, which, after covering the internal surface of the chest, rises from the spine, and is reflected on each side to cover the lungs. This double membrane between each lobe divides the chest into two cavities. It is commonly said, that at the sternum there is a cavity betwixt the laminæ of the mediastinum, and that any matter may be discharged, if lodged there, by a perforation through the middle of that bone. This operation, however, if really required, would be very uncertain; for the mediastinum does not commonly terminate along the middle of the inside of the sternum, but from above, all the way down, it inclines to the left side; so that, if an instrument was thrust through the middle of the sternum, it would pass near an inch on one side of the membrane.

The mediastinum contains in its duplicature the heart, the pericardium, the vena cava, and the œsophagus.

MEDICAMENTA'RIA, (from *medicamentum, medicine*), PHARMACY, is the art of making and preparing medicines, sometimes of preparing poison. Pharmacy hath been distinguished into *chemical* and *galenical*. The first consists of those operations in which fire was the chief medium, for the purpose of separating different ingredients of a compound, or combining different qualities of the body which afforded them, or from the substances thus combined. The second consisted in altering the form or texture of simples, so as to render them fit to be taken, or applied, without attempting any change in their qualities; and in uniting them in compositions of various forms, where each simple was supposed to retain its original properties. But these distinctions have been long neglected.

The operations in pharmacy may be reduced to these four kinds:

1. *Commensuration*, or the adjustment of quantities, necessary for the due administration of simple and compound medicines, as well as for the formation of those very compounds.

2. *Change of form, or texture*, often requisite, both for the convenient administering of simples, and forming compounds. The instances in which this is practised are for the reduction of solid cohering bodies to powder, and of those that partake both of solid and fluid into pulp; for converting salts, and other soluble bodies to fluidity; and, in other cases, the restoring them when fluid to their solid state. The several particular operations by which these changes are produced have been styled trituration, calcination, solution, exsiccation, and crystallization.

3. *Extraction or separation*, in a general sense, not confined to the making extracts of the gums and resins

of vegetables. The different elements of many compound bodies having qualities and powers, when separate and pure, which they are incapable of exerting when their force is suppressed by the quantity or counteracted by the repugnant qualities of the other component parts, are by this means obtained, as acid spirits, testaceous earths, &c.

4. *Composition* is either simple mixture or chemical combination. In the first the different species are intended to act, each according to its own nature, without producing any mutual change of, or alteration in, each other. But this is the less important kind of composition, as single simples will often answer the end of such composition. The second produces many efficacious remedies, which have no adequate substitutes obtained by other means; as the preparations of quicksilver, antimony, saline substances, &c. in which a new compound is produced, differing in its nature and efficacy from any of its component parts.

To execute these several intentions, a variety of methods and proper instruments are employed; hence the terms calcination, crystallization, corrosion, depuration, digestion, distillation, expression, exsiccation, fermentation, fusion, incorporation, precipitation, pulverization, solution, sublimation, &c.

The means of effecting pharmaceutic operations are of two kinds, viz. chemical and mechanical. By chemical are meant the natural media by which bodies can act on, and produce a change in, each other, not explicable from the known general properties of matter, or laws of motion. By mechanical, artificial instruments. For brevity sake in speaking of these two kinds, the first is called media, the latter instruments. See PHARMACIA.

MEDICA'MENTA EXTEMPORA'NEA, (from *medico*, to heal). *Magistralia*, compositions prescribed by the physician, according to the circumstances of the patient, and made up for this purpose only. A variety of these are found in some Pharmacopœias, under the title of extemporaneous medicines, and all the compounds of practice chiefly consist of them. These are the resources of ignorance and idleness; with these the fashionable practitioner provides himself, and prescribes to the name of a disease, with little knowledge of its nature or that of the remedy. To discountenance such impositions on a credulous public, who contentedly employ every one who calls himself a physician, we have seldom added formulæ, and shall not insert any, unless stronger reasons than at present occur to us should be offered. See FORMULÆ.

MEDICAMENTO'SUS LA'PIS, (from *medicamentum*, medicine). The MEDICINAL STONE, which consists of litharge bole and alum, of each ℥ ss. colcothar of vitriol ℥ iij. vinegar ℥ ij. m. evaporated to hardness, formerly used in collyria, &c. as an astringent.

MEDICAME'NTUM, (from *medeor*, to heal). A MEDICINE has been styled any substance capable of changing the state of the solids and fluids of the human body, so as to prevent the increase of disease, or restore health. This definition is, however, both erroneous and imperfect. Terror will prevent a fit of epilepsy, or the attack of an intermitent. Sailing will produce a salutary discharge from the stomach, while neither changes the state of the solids or fluids. It is, indeed, by no means clear that any medicine, except those employed in the

cure of chronic diseases, produces any considerable change in either; and we have found, when we spoke of the arrangement of the articles of the materia medica, that medicines chiefly altered the functions of the body, or the balance of the circulation. The definition seems to have been chiefly intended to distinguish medicines from aliment on the one side, and from poisons on the other. The former was supposed to add to the bulk, or to repair the unavoidable losses; the latter to destroy life. Aliment, however, properly regulated, often removes diseases and the most virulent poisons in smaller doses are very useful remedies; so true is the canon of Linnæus, that "medicines differ from poisons, not in their nature, but their doses."

Though we have treated of the different methods of investigating the power of medicines, it must still be acknowledged that we owe our knowledge of the most powerful remedies to chance, or to the pursuit of objects very different from the results which have been experienced. Chemistry, it is said, has elaborated many remedies, but discovered none. Yet in the pursuit of the imaginary elixir, to prolong life to an indefinite term, some medicines have been discovered, though among these we can neither reckon mercury nor antimony, whose powers were elicited by chance. A happy boldness, or a random experiment, has often added essentially to our stock; but inductive reasoning has only contributed to correct the hasty views of the indiscreet, or to regulate the eagerness of the too sanguine experimentalist.

Modern practice employs few remedies. Yet, as we have more than once shown, simplicity of prescription is the delusive meteor that has sometimes led us astray. (See COMBINATION OF MEDICINES.) In general, however, we agree with an author, whose name has escaped us, that long formulæ are proofs of either ignorance or deceit.

It has been doubted whether there are any specific medicines. As usual, the question requires only to be explained to approach at least to a decision. If it be meant whether a specific stimulus exists, the position must be granted. If, then, there be such, the medicine which possesses this stimulus is, to a certain degree, a specific; but if it be meant whether any medicine can cure a disease by such peculiar inherent powers as are neither warranted by its general properties, or our knowledge of the nature of the complaint, we must hesitate in our answer. The number of supposed specifics, by a more careful investigation, have not been found peculiarly powerful in the disease to which they were supposed to be exclusively adapted; and we have only left on the list, the Peruvian bark and mercury in intermittents and the lues venerea. The former, however, has now lost this proportion of its credit, since other tonics, particularly the arsenic, is found of equal or superior efficacy. The pretensions of mercury to the character of a specific we have lately investigated (see LUES); and when we consider the history of the numerous individuals supposed to belong to this class, we are disposed to conclude, that, as usual, ignorance is the parent of our admiration. Had we any medicine of efficacy to compare with mercury we should discover its relations, and, of course, the cause of its general utility. We have made some steps in this inquiry in the article just quoted.

Universal medicines are now only seen in the columns of a newspaper, or a quack bill. The numberless inconsistent qualities attributed to a patent medicine would almost fix it in this rank; but its real utility is soon seen, if we trace the leading diseases for which it is recommended; and we then find it a common medicine decorated with a pompous title, if it be not an inefficient compound, whose sole merit lies in its name, in its extravagant recommendations, and the credulity and folly of those whose abilities, if exerted, would soon point out the fallacy. See QUACKS and QUACK MEDICINES.

The various distinctions of medicines into general and topical, curative, palliative, or preservative, are sufficiently obvious, though little attended to at present, as the same medicine is now often used with each view. The bark, for instance, is a palliative in restraining the colliquative sweats in hectic, a preservative during the progress of a highly putrid epidemic, and a curative in intermittents.

MEDICINA, (from *medeor*, to heal). MEDICINE. The history of the science which is the chief object of our work, must necessarily detain us for some time; yet, to avoid an article of an extremely disproportioned length, we have broken it in a manner already explained, and shall, in the references at the end, collect the scattered limbs, so as to form one whole. At present, we must examine the history and the progress of medicine; and if, for ages, we find reason to lament its slow advance towards improvement, if we sometimes find it stationary, and occasionally even retrograde, the causes will furnish abundant proof of the imbecility of our boasted reason, of the vast extent of science, of the limited powers of human intellect.

It would be idle to trace at length the probable origin of medicine, or determine whether it be the result of random experiment, of imitation from observing the instinct of brutes, or of divine inspiration. Disease is the lot of humanity; and remedies, or at least attempts to relieve, must be coeval with disordered functions. The obvious means of procuring relief was to expose the patient in the streets, and to obtain, if possible, the advantage of greater sagacity, or more extensive experience; and when either a natural sagacity and opportunities of observation were combined with a ready recollection, they constituted the physician of rude ages, as they often constitute one at the present moment. Priests, as possessing greater leisure and more frequent opportunities of observation, were probably the first medical practitioners, and the most successful physicians were soon deified. Superstition gradually mixed in the scene, and dreams in the temples of the gods, or incantations and amulets, soon corrupted the few lights which experience had suggested. Yet however superstition or design may have corrupted the fountains, the stream was preserved with tolerable purity by the means of the temples; for these were the receptacles of the earliest records, the histories of cases recorded by the patients, and from the temples of *Æsculapius* Hippocrates is supposed to have drawn his best observations. We owe only to a sarcasm of a later era one of the remedies of the sacred fane, viz. the fat of pork in consumptive cases; and, of all animal foods, this is perhaps the least injurious in such cases.

To the Egyptians medicine, with every other science,

is said to be chiefly indebted; and we are told, with a triumphant confidence, of their *Thoth*, who was probably only an allegorical personage, and of *Isis*, perhaps only a regal title. *Horus* the son of *Isis*, the Apollo of the Greeks, was seemingly a real person; but of his acquisitions in medicine we know nothing except from the claims of his adopting parents; who have mixed them too copiously with fable to enable us to discriminate their true value. The real knowledge of the Egyptians in medicine it is not easy to appreciate; for, as we have remarked, (see *CHIRURGIA*), Prosper Alpinus wrote in a period when the later improvements had been carried to Egypt. Blumenbach has, however, shown, that the process of embalming was hastily and rudely conducted; and we cannot attribute any scientific knowledge of medicine to those who confined the management of each disorder to a single family, a single disease to one practitioner, and limited, by law, the use of medicine to a definite period of the complaint. It is said we are indebted to them for the use of clysters; but it is more certain that they excelled in prognostics, which must be the result of careful observation. This talent Galen, while he highly commends, attributes to astrology. Their remedies were chiefly diætic, if we except, perhaps, the nepenthe. The medical knowledge of the Chinese, the Israelites, and the Brachmans, need not detain us. Among each it was inconsiderable; and the chief merits of the first seem to have consisted in punctures with needles; of the second in distinctions between clean and unclean beasts; and of the third in botanical knowledge.

The early Grecian medicine was chiefly chirurgical; and though we hear of internal remedies, yet we have no clue to guide us respecting their nature, as the assertions of some authors nearer the period of their introduction are contradicted by others. Amidst the darkness of the fabulous ages we must acknowledge that the baths of *Hecate*, *Circe*, and *Medea*, seem to show some knowledge of the powers of vegetables externally employed; and the tale of the poisoned shirt of *Deianiria* equally implies the knowledge of deleterious plants, even if some of the circumstances in *Medea's* story should be wholly fabulous.

The events of the Trojan war, which called for the interposition of art, were chiefly, if not exclusively, external injuries; and there is a very slight foundation for supposing, from the language of Homer, that internal medicines were at any time exhibited. Nepenthe was almost the only instance, for the moly was an amulet. If the temples of *Philostratus* were at a subsequent period crowded with votaries, who sought his aid in consumptions, dropsies, intermittents, and diseases of the eyes, we must rather attribute the removal of the complaints to the arts of the priests or the credulity of the votaries, than to the interference of the deceased hero, who is not represented as having possessed any medicinal powers. *Æsculapius*, who accompanied the Argonauts, is not mentioned in the *Iliad*, so that he probably died in the interval; but his fame was preserved in his temples, where the artificers of the priests in choosing a healthy spot shaded with trees, and combining various species of amusement, contributed perhaps more to the patient's recovery than their medicines.

The *Asclepiadæ* seem never, before the time of

Hippocrates, to have practised beyond the confines of their temples; but they had various schools, of which the Coan and the Gnidian were the chief. Their anatomical knowledge, of which they boasted, was rude and incorrect; their practice we can scarcely judge of from the different application of their terms. We should suppose them to have employed drastic purgatives, since they used the elaterium and the grana Gnidia. Yet we learn from Dioscorides how much the ancient elaterium differed from ours, and the *ροξαι*, or *grana Gnidia* may, as the word implies, have been only pills. The *Coan and Gnidian schools* were, however, the chief rivals, and the Gnidian sentences, the compilation of Euryphon, of an age somewhat anterior to that of Hippocrates, is severely criticised by the latter. He complains of the little attention which the Gnidian school paid to the observation of diseases; of the severity of their remedies; their unreasonably increasing the number of diseases, and the little attention they inculcated respecting diet. The only distinguished author of this school known to us is Ctesias, and, from his works, some fragments are preserved.

Of the *Rhodian and Italian schools*, established by the descendants or priests of Æsculapius, we have few remains: of the existence of the latter we find only some imperfect hints in Galen. The former was more distinguished, but its remaining vestiges are few. The medals bear a branch of Balaustines; but this mark is rather referable to the arts than to medicine, as the plant was then almost exclusively used in dying.

The fame of these schools and of the philosophers, for medicine seems hitherto to have been cultivated only as a branch of philosophy, was soon eclipsed by *Hippocrates*, who seems to have been the first to whom the appellation of physician, in its modern acceptation, is due. He first separated it from philosophy, gave it the form of a distinct science, and personally observed the progress of diseases, as well as the effects of remedies; on this account he is styled the inventor of the *medicina clinica*. Yet perhaps the philosophers who preceded him must not be wholly omitted. We are reminded of *Pythagorus* by the *Climacterics*, by the *Critical days*, and his recommendation of the vinegar of squills, in deafness; of his scholar *Alcmæon*, who first described the eye; of *Empedocles*, who, before any other anatomist, dissected with accuracy the ear; and of *Timæus Locrus*, who taught that the nervous system was the basis of the whole body, on which the nutritious substance was gradually extended. *Democritus* was rather a philosopher and a chemist than a physician, and might have ranked with credit in each class were the various hints of his labours collected.

Of *Hippocrates* it is difficult to speak with impartiality in a manner that will satisfy his warm admirers, or those who reject every thing which is not of a modern æra. If we look at him as a physician, when medicine had scarcely escaped from the trammels of superstition, the refinements of philosophy, or the dictates of antiquated tradition, our admiration will rise almost to enthusiasm; for we shall perceive sound judgment, accuracy of reasoning, and acuteness of observation, superior to his æra, or the state of science at that period. But to study and admire Hippocrates at this time is very different. Science has opened newer and more extensive views; diseases are distinguished with

greater accuracy; and the remedies, as they are more numerous, may be more appropriately adapted to the circumstances. If we find a striking description in Hippocrates, we admire it as a mark of superior genius, and wonder how the same event could have happened both in Greece and England. Yet strip the fact of the disguise of system, and it will be found that patient observation would alone have taught it. He fills, however, so vast a space in the medical scene, that some further notice of him and his doctrines will be necessary.

Hippocrates was born in the first year of the, 80th Olympiad, 460 years before the birth of Christ, and was descended from a line of physicians, inheriting the instructions of his father and grandfather, themselves descendants from the *Asclepiadæ*, while his mother traced her origin from the *Heraclidæ*. He died at *Larissa*, it is said, at the age of ninety. He first practised physic at *Thasus*, afterwards at *Abdera*, and at last in *Thessaly*; but his chief residence was at *Cos*, whence the *Coan school* became for a long time the successful rival of the *Gnidian*. All that has been added to these few events is doubtful. That his instructors were *Herodicus* (or *Prodicus*) and *Democritus*, rests only on the attention which he has paid to the gymnastic art, as well as to anatomy; and the philosophy of Hippocrates is more nearly allied to the tenets of *Heraclitus* than of the *Abderite*. As Hippocrates was a great traveller, he might have attended the lessons of *Prodicus* in *Athens*, where he chiefly taught, and might there have been acquainted with his brother *Gorgias*, whom he afterwards attended in his medical capacity in *Thessaly*, when worn down with old age; but we have no records of his having ever practised at *Athens*.

The other tales either to his honour or discredit are too idle to detain us. Had he violated or burnt a temple, Greece could have afforded him no asylum. Had he been greatly instrumental in relieving those affected with the plague at *Athens*, *Thucydides* could not have stated that medicine was of no advantage in that epidemic. The oration of *Thessalus* the son of Hippocrates on the subject of the honours decreed to him, must be spurious; for at that time the sage was but thirty-one years old. The request of *Artaxerxes*, which he is said to have refused, is also wholly inconsistent with the crime supposed to have driven him from *Cos*. The tale of his being sent to *Democritus* by the inhabitants of *Abdera* seems only one of the many sneers the stupidity of the *Abderites* scattered in ancient history; and *Reland* has shown, that the imputed letter was written by *Epictetus*. The time of his death is equally uncertain.

Under the name of Hippocrates we have received works of very different value. Those of his predecessors and successors are confounded with his, partly from his having appropriated some of their remarks, in part from the high character he had acquired; and from several of his descendants having retained his name. The chief cause, however, of the many spurious works attributed to him, is the avarice of the collectors of *Ptolemy*, who, when he founded the library of *Alexandria*, endeavoured to obtain, at the most extravagant rates, the works of every author of reputation. Every thing under the name of Hippocrates was eagerly received, and it was thought of little importance whether they proceeded from the first, second, or third

of that name: the reports were not sifted with minute discrimination. To distinguish the real works of Hippocrates has been consequently a problem of no little difficulty. At the expiration of 500 years, this task was attempted by Galen, who, to an intimate knowledge of what the successors of Hippocrates had written, possessed a discriminating genius, and a critical discernment of the style and manner of the Coan sage, which peculiarly fitted him for the task. Mercurialis, a man of the most extensive erudition, Haller, a physician of vast information, capable of the most incredible labour, and Gruner, possessed of all the indefatigable diligence of his nation, have laboured in the same field. They have assumed, as a principle, that Hippocrates was a man of singular abilities, extensive information, consummate candour, and modesty. By these tests they have tried every imputed work. Though perhaps the principles might not be readily conceded, yet, as they will certainly point out to our attention the most valuable works, we shall give the result of their labours.

The undisputed works of Hippocrates are said to be the first and third book of the *EPIDEMICS*; two books of the *PRÆNOTIONES* (a different work from the *Prænotiones Coacæ*, published by Elzevir in 1660, by Duretus at Paris, and with commentaries by Hollerius at Leyden, which is very certainly spurious), containing the *Prognostics*, and the second book of the *Prorrhetica*; *De Diæta in Acutis*, in opposition to the Gnidian sentences; the *Aphorismi*; *De Aere, Aquis et Locis*; *De Natura Hominis*; *De Humoribus Purgandis*; *De Alimento*; *De Articulis*; *De Fracturis*; *De Capitis Vulneribus*; *De Officina Medici*; *De Locis in Homine*. This is nearly the enumeration of Haller; but Galen and Haller seem to have admitted tracts among the Hippocratic works, with too great facility. Gruner, who like Haller considered brevity, gravity, and the absence of theoretical reasonings to be the true test of the genuine writings of Hippocrates, differs in the application. He admits the *oath*, but rejects the treatise, *De Natura Hominis*, *De Locis in Homine*, *De Humoribus*, *De Alimento*, et *De Articulis*. Whether the *oath* be admitted or rejected, is of little importance; since it must be considered rather as an object of curiosity than of utility. The first of these rejected works was admitted, with hesitation, by Galen and Mercurialis, as containing many passages very distant from the manner and doctrines of Hippocrates; but it was retained, as containing some facts of importance. The second, though admitted by Galen and Cælius, and though it agrees, in general, with the practice of Hippocrates, has been suspected on account of some passages of a very different description. Haller only asserts that it *may* be his work; and Mercurialis, who ascribes it to Hippocrates, thinks that he did not live to complete it.

Gruner and Mercurialis reject the tract *He Humoribus*, but add, that it merits attention. It has been indeed commended in every age, and illustrated with commentaries by Galen, Duretus, and Gunzius. The tract on *Aliment*, on the contrary, imitates only the terseness of Hippocrates, but betrays the author to be of a later æra, by the doctrines respecting the arteries and veins. The book on the *Joints* is evidently the work of Hippocrates, or, at least, of the author of the tract *De Fracturis*, and universally admitted. It contains

also an account of the luxation of the thigh, which the history of medicine uniformly attributes to Hippocrates, by recording a controversy between him and Ctesias on this subject.

Yet even the undisputed works of Hippocrates must be received with some hesitation. The criteria by which they are decided are, we have said, not infallible; for they assume a degree of uniform excellence, which perhaps few have possessed. The tract *De Aere, Aquis et Locis*, shows the author to have been an European; and various passages even in the most genuine works, may be adduced to prove that interpolations have crept in. Where then can we draw the line? or need the line be drawn?

We have enlarged on this part of the subject to add the only conclusion which can be admitted, that the undisputed works of Hippocrates show rather the state of medicine in the earliest eras than form what may be styled the system of an individual. They are therefore objects of curiosity, rather than use; for the most important facts are scattered in a variety of modern works, and within the reach of the greater number of readers. Yet the writings of Hippocrates merit attention. Where the title of doctor is assumed merely as a claim to receive the fee of a physician, it is of little importance whether the practitioner can read: the world is contented to take his talents on trust; but the man who claims the rank of a regular, well instructed, physician, should not be ignorant of the language of Hippocrates, or of the state of physic at the earliest period of recorded observations. He will derive no little satisfaction from the polished terseness of the Hippocratic language, from the candid relation of facts, whether favourable or otherwise, from the firm undeviating integrity, which seems to have regulated the conduct of this father of medicine.

We have been led also to this inquiry from other views. Various are the authors who have treated of Hippocrates and his system, without knowing that, in the same volume, works most unworthy of any author of credit were confounded under his name. Each has been quoted with the same indiscriminate complacency, and it may be easily conceived what a motley mixture must be the result. Having thus pointed out where his real sentiments may be found, we shall very shortly point out what they apparently were.

The tenet of Hippocrates, that a knowledge of nature is the first principle in medicine, has been quoted with great zeal, to prove that he who saw this position in so strong a light must have been acquainted with the structure and the functions of the body. Yet even this axiom seems not to have been suggested by Hippocrates, as it occurs in one of his doubtful works. That nature preserves health and cures diseases is a tenet more obvious, and must have often occurred in a practice so inert as that of the Coan sage. His anatomical knowledge was inconsiderable. In his work on the bones, one of doubtful authority, he describes the spine as consisting of twenty vertebræ only. The error is indeed corrected towards the end, but apparently by another hand. The *vesiculæ seminales* are expressly described as a series of vesicles on each side of the bladder. This fact has been quoted to show that he dissected human bodies; but the tract, in which the observation occurs, is pronounced to be spurious, even by Galen. That Hippocrates was acquainted with the circulation of the

blood, as some authors have contended, no longer requires a single remark.

Though his genuine account of the structure of the genital organs is confessedly incorrect, yet his ideas that the male and female semen are mixed in conception, that the sex is determined by the most powerful, and that, if the semen escapes from the female, impregnation is prevented, are principles still supported by many physiologists, and are, on the whole, highly probable. The reciprocal action of the warm and cold spirit, in promoting the growth of the fœtus, is wholly imaginary. The soul, he supposes, is drawn in with the air; not with air as such, but as a vehicle of water and fire, and communicated through the vessels of the placenta to the fœtus. His theory of the cause of labour pains, from the exertions of the fœtus, in consequence of the want of nourishment, though long supposed to be true, will scarcely bear the test of rigorous examination; and indeed every supposed cause of labour supervening at the end of the ninth month appears to be equivocal. The reason which he assigns for the life of a fœtus of seven months, while one of eight is generally dead, appears to be too refined, and in part imaginary. It has been said, that a woman, accused of adultery, because her child was like neither supposed parent, was acquitted on Hippocrates suggesting, that a picture, which resembled it, might have been in her bed chamber, which, on examination was found to be true. The story is told, however, by an obscure writer, Hieronymus; and Galen, who relates it as the tale of a former age, does not attribute the decision to Hippocrates.

To engage, however, in any extensive enquiry respecting the physiological doctrines of the Coan sage would be idle, since much was fancy and more probably conjecture; but above all, on account of the latitude of expression which he employs. Thus *νευρον* signifies not only nerve, but ligament and tendon; *φλεψ* not only a vein, but an artery, or an excretory duct; and *αιμα* means not only blood, but any watery fluid; and the nervous fluid the air inspired, which mixes ultimately with all the fluids of the body.

It is more clear, that he supposed the existence of four fluids in the body, blood, phlegm, yellow and black bile. Their common source he supposed to be the stomach, but each had also its peculiar origin, viz. blood from the heart, phlegm from the head, yellow bile from the gall duct, and black bile from the spleen. The last organ, in his opinion, attracts not only the black bile, but water also, which it conveys to the urinary organs or to the belly. This doctrine of the four humours has been the foundation of the system of Galen, and still infects the theory of medicine. See TEMPERAMENTA.

The Hippocratic pathology might be offered in a neat compacted system, were the book *De Flatibus* certainly written by the father of medicine. It is, however, generally and deservedly removed to a later æra; yet Galen employs the flatulency when mixed with the bile, as the cause of fever. The cause of epilepsy, as assigned by Hippocrates, is so reconditæ, and so totally at variance with what anatomy teaches, that it would be useless labour to enlarge on it. Yet this, and some other of this author's disquisitions, show with what eagerness he endeavoured to transfer his observations on the appearances found in the dissection of brutes to the

human system. We may here remark what an examination of the works of Hippocrates for this purpose has suggested, that the boasted *το θείον* is introduced hastily and abruptly, greatly resembling an interpolation. In other parts of our work we have followed the herd of authors, and attributed it to a fixed systematic opinion.

As Hippocrates speaks of the rising and setting of the dog star, of the pleiades, &c. it has been supposed that he attributes diseases to their influence. If, however, his works be examined, it will appear that, in such places, he only endeavours to fix the seasons with greater accuracy. It is evident, indeed, that he examines the influence of different seasons, the prevailing winds, the situation of marshes and mountains, with great precision, and pays peculiar attention to the age, mode of life, constitution, and diet of his patient. The histories or daily progress of diseases he has described with great accuracy and perspicuity; nor are his remarks, though not strictly applicable in our climate, and in constitutions so totally differing by a very opposite mode of life, wholly useless at present. Observation seems to have suggested what have been styled critical days; nor, though he hints at a supposed harmony of numbers, is there any real evidence that the doctrine was suggested by it. His observations on the pulse are few and indistinct; on the urine, numerous and minute; on the excretions either from the lungs, from the stomach, or bowels, peculiarly distinct and pointed; on the appearance of the features and the state of the body, full and discriminated. Yet, with all these aids, he still considers the prognosis in acute diseases as uncertain.

The practice of Hippocrates must be divided into his diætic, his surgical, and his medical system. The chief diætic work under his name is attributed by the critics to Polybius, his son in law; but there is much reason to think, that the rules are derived from the sage himself. In general, in this work, as in other parts of his writings, he commends moderation, and a quantity of aliment in proportion to the exercise used. In some of the tracts attributed to him he speaks of the comparative utility and effects of horses, asses, foxes, and hedge hogs flesh. Where excess has been indulged, he mentions the advantages of vomits, purgatives, clysters, frictions, baths, &c. When persons were seized with acute diseases, he employed low diet, and forbade exercise: we find it injurious at this moment.

His practical rules are sound and judicious; yet, perverted by fashionable systems, they have been found most fatal. Acute diseases are, he thinks, cured by nature, and the physician must look on and attend: those which have a fair proper crisis we must not disturb. What ought to be discharged must be discharged at the most convenient outlets, and at those where the tendency to evacuation is perceived; but concocted fluids only must be attacked by medicines, not crude ones, unless they are turgid. It is impossible to convey more sound and judicious practice in fewer words, yet it has been mistaken so much, that evacuations have been forbid in the beginning of diseases, and volumes have been written to explain the meaning of *turgid matter*, or rather to conceal it. The real meaning of the rules, examined in their literal sense, or in comparison with the other passages of his undisputed works, is this: What must be discharged will be properly,

evacuated by the most convenient outlets. We are not, for instance, to urge purgatives when there is a tendency to perspiration, or sudorifics when expectoration is necessary. *Concocted* fluids are only to be evacuated, not *crude* ones, unless they are turgid. This is the fatal sentence; for the term concocted has been applied to the state of the fluids only after a long continuance of fever, and it has been supposed that fever must continue before evacuations are attempted. Whatever be the meaning, however, the interpretation must be limited by the term turgid, which in fact means only full. Thus a fullness of the epigastrium, of the abdomen in general, bilious vomitings and diarrhœas, redness of the eyes, and a heaviness of the head, are distinctly noted as marks of turgescence. These are the cases in which modern practice employs evacuations, and these are the symptoms which, even with Hippocratic rigour, would be truly found to indicate them. Yet to wait for concoction has been the fatal rule, which has kept febrile patients in bed with closed windows and curtains, with fire in the dog days, the addition of blankets, and the most heating medicines for many weeks. At the moment of our commencing practice his plan was not wholly exploded.

A rule, less liable to be mistaken, was, that diseases from repletion must be cured by evacuation; and the contrary. Rest is equally the remedy for labour, and labour for indolence; and, in general, medicine consists in adding or taking away, according to the nature of the cause. Every attempt, however, to change a continued habit must be gradual, for every excess is dangerous.

If evacuations cannot safely take place from the most convenient parts, a revulsion must, according to Hippocrates, be attempted, and the nearest emunctories should be preferred; for the discharge, he adds, is not salutary from its quantity, but from its freedom and the ease with which it is borne. When, however, it is the object to weaken, the discharge must be excessive. If the practitioner should not at once succeed, he should not hastily change his plans, but consider whether any thing has been omitted, or, for a time, rest to see what nature will point out. When the patient appears to yield to the disease, he forbids further attempts; but those, he remarks, with an oracular uncertainty, who are not relieved by medicine are relieved by iron; those who yield not to iron are cured by fire; and those on whom fire makes no impression are incurable.

The milder laxatives of the "divine old man" were the juice of the herb mercurialis, cabbage, the leaves of elder, or a decoction of beet root with salt and honey; various kinds of milk, either boiled or in the form of whey. These in larger quantities were sometimes employed to produce vomiting. As assistants to these, he employed clysters and suppositories; and, when more active drastics were necessary, the hellebore, not, however, without the precaution of premising the most cooling diet. He was anxious also that whatever might prevent hiccup and convulsions should be ready, and assisted their quick operation by clysters.

To the white hellebore he usually joined the sesamoid; to the black, the peplium, supposed to be a species of esula, or the portulaca, though by some authors thought to be the papaver spumeum of Dioscorides. We might fill pages with conjectures respecting the present names of these plants, but must leave the

question at last in uncertainty. Hippocrates certainly considers what he styles the white poppy to be a purgative, and Pliny refers a kind of poppy to the genus tithymalus. The peplium seems, from other parts of Hippocrates's works, to be a carminative, and the cummin or the anise seeds appear to be occasionally substituted for it. Other purgatives, recommended by the Coan sage, are the grana Gnidia, the colocynth, the thapsia, the cyclamen, with the flowers and scales of copper, though the last are chiefly employed externally. Scammony and elaterium he commends for pessaries; but the latter was also given internally, as he advises the milk of a woman or a she goat which have taken elaterium, as a purgative for children. It has been suspected that, in this passage, elaterium is inserted instead of veratrum, which goats greedily devour, and which acts on them as a cathartic. It is singular, however, that the particular purgatives, especially the drastics, are mentioned only in the tract De Morbis Mulierum, which is supposed to be from the school of Gnidus, and older than Hippocrates, since no mention is made of aloes, which was brought from India through Egypt in his time.

The head, according to Hippocrates, was particularly evacuated by the grana Gnidia, hippophae, a thorny shrub which discharged a bitter milky juice; the stone magnesia, which is undoubtedly the load stone; and the tetragonum, supposed by Galen to be antimony, but by modern botanists to be the juice of one of the fir tribe, several of which are purgative. In general, Hippocrates used purgatives in chronic diseases; but he certainly employed them in acute ones more freely than the greater number of the more modern practitioners.

The diuretics prescribed by Hippocrates were the leek, onion, mercurialis, wild parsley, &c. with wine and honey largely diluted, sometimes the warm bath. Cantharides, however, he orders in dropsies; and five, with the head, feet, and wings taken off, to expel the scurridines and bring on the catamenia. It is not certain, however, that so many were always swallowed: in dropsies he gave three only.

To purge the lungs a singular method was employed. If there was reason to suppose that an abscess had formed, after a peripneumony, a decoction of different acrimonious plants, with honey, &c. was directed to be poured into the trachea, the passage to which was opened by drawing out the tongue. Galen, however, has long since informed us, that the whole process was taken from the Gnidian school.

The uterus was stimulated by the most active pessaries, clysters, and injections, or by partial vapour baths (incessus) composed of the same ingredients. He attributed much to perspiration; but produced it chiefly by warm diluting liquors, by bathing, and covering the patient with warm cloaks. His ptisans, decoctions of barley of different richness, are often mentioned.

He drew blood by venesection, and by scarifications more or less deep, chiefly near the head; yet he did not repeat the evacuations frequently, lest, by intercepting the current of blood to the head, apoplexy, convulsions, or inflammations might be induced. When the voice was affected, he divided the vein of the right arm; in pleurisy and peripneumony, the internal vein of the side affected: some directions are subjoined, respecting a division of the veins under the tongue, or in the hands.

In inflammations of the chest, he sometimes bled till the patient fainted. He bled topically with cupping glasses, and sometimes directs the necessary size. The lancet, he observes, should not be too pointed, that a free passage may be afforded to the more viscid fluids.

When he wished to alter the crisis of the more fluid, or of the more solid parts, he chiefly employed diet; and he is consequently copious in describing the powers of particular diets as cooling or heating, diluting or drying, as laxative or constipative. A large share of the tract *De Victu Acutorum* is employed on this subject, where the ptisans again frequently occur.

To check excess of motion, he seems to have very rarely used opium. In what he styles strangulations of the uterus, he advises το υπέρτατον μιλκωνιον, the soporific meconium: the σπες μιλκωνος seems to be the papaver spumeum, the peplum, perhaps the wild purslain. He recommends the mandragora in a dose below that, which produces delirium, and thinks it useful in the violent paroxysms to which those affected with melancholia are sometimes subject. The juice of the mandragora, and the wild cucurbit diluted with milk, is to be injected into the anus to relieve prolapsus, or bleeding piles, and into the vagina to evacuate the vessels of the uterus. But to cure quartans he mixed the mandragora with hyoscyamus, silphium (probably asafœtida,) and trefoil, giving them together in wine.

To correct rigidity he employed baths, fumigations, and gargles. Oils, impregnated with different flowers, sometimes with aromatics, were also freely ordered; cataplasms and ointments, sometimes stiffened with wax, but scarcely in any instance consolidated into what may be now called a plaster, were frequently employed. The oils were generally rubbed in after exercise, and thence called *acofa*, relievers of fatigue. It was an idle fancy of the alchemists that Hippocrates was an experienced chemist.

The surgery of Hippocrates is scattered through a great number of tracts, but this part of the subject has been anticipated in the history of surgery. (See *CHIRURGIA*.) Yet, on recurring to that article with a more circumspicet eye, we perceive omissions which we shall now endeavour to supply.

A minute attention, which seems to have prevailed in the Gnidian school, to the form of bandages, he rejects as rather curious than useful. The patient, he remarks, requires assistance, not ornament; and whatever does not contribute to his ease or his relief, he thinks undeserving of attention. He penetrated bones with an instrument not unlike the modern trephine, and even the ribs, to evacuate water collected in the chest. The management of fractures, though the instruments were somewhat rude, seems, on the whole, judicious: no plasters were applied till after the æra of Paulus Ægineta. The eye, in inflammations, was scarified by the friction of the rough Milesian wool.

We have enlarged on this subject because we have not found the Coan system fully and impartially stated; and because the practice of Hippocrates, like an overruling genius, has continued to lead us, by imperceptible threads, even to the present æra. Subsequent to his time his descendants and disciples continued in the same line, and for many ages little improvement was made in practice, and but few innovations occurred in physiology. For the latter we are indebted to *Plato*,

whose fancies on this subject are amusing, and, but that we have little room for amusement only, might for some time detain us. The names of Hippocrates' successors, and we could add scarcely any thing to the catalogue, would not be interesting; but we were somewhat surprised among them to find the elder and younger Dionysius. We could easily conceive that the elder, as was reported, delighted in witnessing the most painful surgical operations; but the idle dissipated character of the younger forbid us to expect from him any mental exertion. It is suggested, however, that the barbers and perfumers shops, for he was as condescending and familiar as our fifth Henry when prince of Wales, were called *ιατρεία*, and that it might therefore be truly said that his time was employed *ε'ιατρείαις*, but not in medical disquisitions.

From the time of Hippocrates to that of Ptolemy Philadelphus few were the medical practitioners, and these rather distinguished for fancy and refinement than any improvement in the art. *Diocles*, already noticed in the history of surgery, rescues this period from total insignificance. Yet, even at this time, when authors contended that no blood naturally entered the arteries, and the arterial vibrations were attributed to a *pulsific conatus*, the pulse was attended to and employed among other prognostics. The fame, however, of the medical practitioners was eclipsed by that of *Aristotle*, who flourished at this time; a man to whom every branch of natural science was highly indebted, who alone united the most comprehensive views, the acutest genius, and the most unremitting diligence, and who has only been disregarded by those who have not talents to appreciate his labours. His two books on medicine are unfortunately lost; his anatomy, in the works which remain, is not on the whole correct, and his physiology somewhat fanciful. These were, however, the faults of his æra, not his own. Whatever were the errors of his physiology, and philosophy, both were adopted in general by Galen, and more exclusively by the Arabians; so that their effects were most extensive. The vast knowledge which Aristotle possessed in the three kingdoms of nature is sufficiently understood; to his instructions we are indebted for what Theophrastus has collected, and perhaps for the fatal knowledge which Thrasyas is said to have possessed of the deleterious qualities of vegetables. The other physicians of this æra do not merit the slightest notice.

The prominent objects which next offer themselves to our attention are *Herophilus* and *Erasistratus*, the great founders of the Alexandrian school, at least the powerful supporters of its credit. Erasistratus we have styled the elder, but the chronology of this very early period is uncertain. *Erasistratus* was a physician of some eminence, but he applied to anatomy at a very late period of his life, and with great candour recanted, in consequence of his discoveries, some of his early opinions. He certainly approached very near the secret of the circulation, but could not understand the use of a double heart. He supposed digestion to be performed by attrition, and violently opposed the humoral pathology of his predecessors. His own system rested on the idea of the arteries containing only a spirit, and that diseases, particularly fevers and inflammations, arose from their admitting blood. He was apprehensive of bleeding, lest the blood should find a way from the

veins to the arteries; of purging, because Pythagoras had forbidden it. He reduced his patients by abstinence, or by violent exercise: venesection he supplied by ligatures; purgatives by slight emetics, or by clysters. He recommended simple medicines, and violently reprobated the complicated formulæ of that æra.

The school of Smyrna, in which Erasistratus taught, was undoubtedly famous; but there is reason to doubt whether the medals which remain, supposed by Mead to have been struck in honour or commemoration of this seminary, had really such an object. The figure of Æsculapius, which they bear, is so common on medals where there is not the slightest suspicion of their being intended to commemorate physicians, that the image carries no conviction. The names added seem to be those of magistrates or priests; indeed these offices were sometimes united, and should the name of a physician occur, it rather belonged to him in his official than his medical capacity.

Herophilus, though chiefly distinguished as an anatomist, was, however, according to Galen, acquainted with the whole science of medicine. He, as well as Erasistratus, was accused of dissecting criminals alive; nor can we at this time deny what Celsus has expressly asserted, and Tertullian confirmed, notwithstanding the silence or the evasions of Pliny. He certainly first saw the lacteals in goats, and gave his name to many parts of the human body, which he first described. We are informed by Plutarch that he considered the function of respiration to be performed by two systoles and two diastoles, but his account is far from being intelligible. Every complaint, he thought, was owing to humidity. In pleurisy, one portion of the lungs was only, in his opinion, affected; in peripneumony the whole viscus. He was peculiarly minute in his prognostics from the pulse, and appears to have illustrated it by a geometrical construction; but Pliny, to whom we are indebted for the account, seems to think that the full explanation had not reached even his æra. He chiefly depended on vegetable medicines and used hellebore freely. When the whole system was in confusion, he thought the disease would escape. He was also fond of gymnastic exercises, and is quoted by Eustathius in his notes on Homer, unless with some able critics we read Herodicus, the first patron of gymnastic exercises, for Herophilus. The followers of Herophilus were numerous, and their names are preserved; but they are spoken of with little respect by Galen, as arrogant and loquacious; and it is singular that not a single one has been celebrated for his anatomical acquisitions.

The indifference to anatomy seemingly arose from the gradually increasing influence of a new sect, whose origin has been traced to *Acron* of Agrigentum, the rival of Empedocles, and the cotemporary (probably) of Hippocrates, I mean the EMPIRICAL. Its real author, however, according to Galen, was *Philinus of Cos*, the pupil of Herophilus; though *Serapion*, on the authority of Celsus, has been considered as the first and chief of this sect. Herophilus himself may have dictated this schism, by lessening the authority of Hippocrates, whose anatomical descriptions were found by Herophilus to be seldom consonant with the human structure. It appears, however, more probable that the new sect arose from the superstitious dread of the Grecians, who thought themselves polluted by the touch

of a dead body, for Herophilus dissected in Egypt; and this I conjecture to have been the case, since the first mark of disaffection expressed by Philinus was the aversion to anatomical dissections; nor can I find, after a very minute enquiry, that he proceeded farther in his heresy. He wrote also some tracts on plants, and commentaries on Hippocrates; but very little is known of him.

Serapion of Alexandria, first openly contended that all dogmata in medicine were useless or injurious. The result of casual information, when pursued in practice, they called imitation; frequent imitation an experimental habit; and they formed rules, more or less general, according to each. When they transferred what they had observed respecting one disease to another, they called it epilogismus; and the result of their own observation, autopsia; that of others, history: the two last with analogy (epilogismus) they styled the tripod of medicine. This is the equivocal triplex sermo which Galen accuses Serapion of preferring to the ancient dogmata.

Of the empirical practice *Cœlius Aurelianus* has given some specimens: castor, cicuta or opium, and henbane, were the chief remedies. In the account of epilepsy the reader will find almost the whole of the materia medica of the empirics; but they usually premised bleeding, vomiting with veratrum album, and purging with black hellebore and scammony.

The followers of Serapion have not been distinguished in the annals of medicine; and one of the last, whose name merits our regard, *Heraclides of Tarentum*, deviated, we suspect, from his predecessors, since he commented on all the works of Hippocrates, and is praised by Galen. His tracts on internal affections and on diet were also commended; but, in general, the empirics were attentive to diætics and to surgery. Celsus praises their ordering moderate and frequent potions in fevers, though he disapproves of their management of quartans. Galen describes an antidote of Heraclides, which consisted of the juices of cicuta and henbane, of each four drachms; of castor, white pepper, costus, myrrh, and opium, of each a drachm. These were mixed in two glasses of wine, and evaporated in the sun till the whole was of the consistence of an electuary, and the quantity of a horse bean given with two glasses of wine in all cases of bites from poisonous animals, in pains, and in strangulated uterus.

We have arrived far beyond the period when Celsus tells us that medicine was divided into three branches, diætics, pharmaceutics, and surgery, yet we have seen the same authors treating of each; and though the proportion of their attention has been varied according to their fancies and opinions, yet the same author has seldom wholly neglected either. The language of Celsus seems therefore to have been mistaken, and in *Tres partes deducta* seems to mean the particular attention paid to each branch; for surgical knowledge often exerted in the moment of necessity, and diætics, which require domestic attention, could form no part of the systems of the priests. Some, however, were particularly famous for branches of the science, which they had particularly cultivated, and we know that lithotomy, for instance, was practised by exclusive operators. The empirics, we have indeed remarked, were peculiarly attentive to diet; but there is no evidence of any real separation, except in the case of the operation for the stone. On attentively examining this subject, we

find traces of compounders of medicines (pharmacopolæ) distinct from the practitioners. Theophrastus, for instance, distinguished the Pharmacopola Thrasyas from his pupil Alexias, who was acquainted with the whole art of medicine. The same author asserts that Eudemus of Chio was accustomed to prepare twenty doses of hellebore in one morning; and it appears, from the subsequent sentence, that the pharmacopolæ kept open stalls, not unlike, probably, the stages of modern mountebanks. The herbalists were a still inferior class, subservient to the pharmacopolæ. The successors of Heracleides are not of sufficient importance to detain us, for much remains to fill up the picture.

Greece was now become subservient to the superior genius of Rome, and we must there look for the progressive steps of medical improvement. Rome, formed by the rude tribes of ferocious banditti, wanted for many ages little more than those surgical aids which their mode of life rendered indispensable. Epidemic fevers, however, were at times violent and fatal, from the Pontine marshes, which were at no great distance from this capital of the world. Yet, for nearly 600 years, they were said to be without medical aid, and their only resources to have apparently been blind empiricism, superstitious charms, or religious ceremonies. Temples seem to have been erected to FÆBRI, and their most destructive enemy, thus raised to the rank of a goddess, was worshipped. In various parts of the city subordinate deities of the same kind were introduced; and no less than three goddesses, Intercidona, Pilmna, and Deverra, were propitiated by offerings to confine Sylvanus, who was supposed to be inimical to women in child bed. In the year 321 ab urbe conditâ, a temple was erected to Apollo for the health and safety of the Roman people; and in 470 Æsculapius, or rather his emblem, a snake, was brought to Rome by a solemn embassy, sent for the purpose to Epidaurus. The snake took refuge in an island in the Tiber, and there the temple of the god was erected. This fact is of considerable importance in the history of medicine, since it proves that the worship of Æsculapius was continued in Greece in that era, and consequently that traces of the records from which, as a sacred fountain, Hippocrates drew a great part of his observations, were still preserved. Some of the votive tablets hung up in this new temple are preserved by Gruter, and of a date so late as the age of the Antonines; but these are in Greek, and seem to have owed their origin to the gratitude or superstition of some Greeks who at that time resided in the city.

It indeed appears singular, that, while Rome was so little distant from Naples, a Greek city, who traced their original to the Rhodians, among whom Æsculapius was worshipped, they should have had no traces of medicine; especially as the Pythagorean philosophy was brought from thence, or from the farther provinces, styled Magna Græcia, to the Roman kings. The testimony of Pliny, however, is positive; nor is it repelled by Dionysius of Halicarnassus, who remarks, in two distinct epidemics, viz. of the years of 282 and 401 ab urbe conditâ, that the disease was so violent, as to baffle the skill of the physicians; for such would be the language, whatever the medical aid might have been. The stern patriotism of *Marcus Cato* seems to have prevented the increasing influence of the Grecian physic;

and, from authority, or complaisance, Pliny fixed the period of 600 (strictly 535) years, during which no physicians were to be found in Rome. It must be obvious, as we have already insinuated, that this could not be strictly true; for some resources, either ridiculous or superstitious, must have been sought for when disease occurred. The diætetic system, the virtues of cabbage, adopted from the school of Pythagoras, and the superstitious attachment to the Asclepiadæ, could not have sufficed; but we find little to substitute in their place. The Roman records fail us, and the authority of Cato is supreme. We mean not, in this account, to allude to a law said to be introduced by Cato, prohibiting the Grecian practice; for at the time of the arrival of Archagathus from Greece, he was but fifteen years old; but, as we have remarked, to his influence in preventing the increase of the prevailing fashion. The fame of Archagathus quickly faded; for, though at first styled *Vulnerarius*, he was soon stigmatized by the appellation *Carnifex*. Of the practice of Cato, who wished to supersede the Grecian system, we have hints from Pliny, Plutarch, and his own remaining works. He did not enjoin abstinence, but allowed his patients to eat vegetables (Pliny says cabbage, exclusively), ducks, pigeons, or hares. In fractures and dislocations, his remedy was a charm, consisting of hard words, without a meaning. The English reader may find some amusement on this subject in the memoirs of Martinus Scriblerus.

The bad success of the severer practice of Archagathus soon rendered his successors more gentle in their operations; but that some remains of the active Greek surgery continued to prevail we learn from Plutarch, who informs us, that, when C. Marius suffered the extirpation of the varices of one leg without a groan, he declined the attempt on the other, saying, that the advantages did not compensate for the sufferings.

Numerous works have been written to prove, that physicians at Rome were slaves, liberti, or foreigners. The opponents of this opinion have been equally voluminous. We must, as usual, give the result of our inquiry without engaging in the controversy. It seems clear that the greater number of practitioners were of the description mentioned, but it is equally certain that many were of a superior character. Archagathus himself was received at first with great ardour, and a house purchased for him; nor, on the decline of his credit, was he apparently deprived of it. He was also raised to the rank of a Roman citizen; and the Aquilian law declares, that, if any physician neglects a slave after any operation, he shall be pronounced guilty of a crime. By the same law, an action will lie against a physician, who, by the unskilful use of the knife or of medicine, shall kill a slave; and Ulpian decides, that a midwife, in the same circumstances, shall be pronounced equally guilty. These regulations must relate to free men, and the Aquilian law is confessedly anterior to the age of the Cæsars, for all physicians were by Julius Cæsar raised to the rank of Roman citizens. Varro is also explicit on this subject, when he discusses the question for what farms it is preferable to have artificers, among which he reckons medical assistants, occasionally hired, and to what kinds it is better to have slaves attached. In the time of Cato, also, the Phœnicians had been driven from Sicily by the Romans, and the Macedonians from Greece. The Grecians had therefore recovered a great

share of their former liberty. As their language was fashionable, their manners pleasing, their demeanour obliging, perhaps approaching to servility (Juvenal), it is not surprising that they should flock to Rome, nor that they should be favourably received.

Medicine obtained no inconsiderable advantages from the legacy of *Attalus Philometor*, the last king of Pergamus, who left the Romans his heir. We are told by Galen that the Pergamens were the rivals of the Egyptians in collecting books; and Philometor was peculiarly attached to gardening, and the examination of the powers of poisonous plants. It has been said that this study was rendered subservient to the most cruel purposes, but of Philometor's cruelty we have no evidence. We know that he wrote some tracts on agriculture, which Pliny and Varro have praised; that he engaged in metallurgic experiments, and in modelling with wax: Galen describes also, with commendation, some medicines invented by him. To the patronage and to the assistance, probably, of Philometor, we are indebted for the works of *Nicander*, particularly the *Theriaca* and *Alexipharmica*. His collection of remedies, the prognostics translated from Hippocrates, and a work in verse, *De Re Rustica*, highly commended by Cicero, are lost. A long fragment of the last is preserved by Athenæus, which shows that it contained many observations relative to medicine. The poems which remain were highly valued by ancient authors, as we find from the numerous commentaries on them; and whatever may be said of Attalus' more philosophical or patriotic pursuits, it is still probable that experiments on *condemned* criminals furnished Nicander with many facts. The history of medicine describes Thrasyas as attentive to poisonous plants, and perhaps their antidotes, fable speaks of Deianira, Hecate, Circe, and Medea, but animal poisons were first considered scientifically by Nicander. The king of Pontus, about the same period, engaged in a similar investigation; and to his experiments in pursuit of antidotes we owe the famous medicine, which bears his name, Mithridate. The receipt, with many others, was taken from the cabinet of Mithridates, by Pompey, who directed his freed man Lenæus to translate them. The original formula however of this famous alexipharmic consisted only of two dried nuts, as many figs, twenty leaves of rue, and a grain of salt. To this remedy we shall, however, return.

The pursuit of this subject has drawn us from our chronological clue; for, previous to the conquest of Pontus, *Asclepiades* flourished. He was not a Roman, but born in Prusia, a city of Bithynia. He was by profession a rhetorician, an Epicurean, and the friend of Cicero. If we may trust the report of Pliny, *Asclepiades* came to Rome without any knowledge of medicine; and, failing in his attempts as a rhetorician, he with little preparation professed himself a physician. He was the first of this profession who gained general esteem in the capital of the world, and whose name has reached posterity. Pliny gives a long account of the artifices by which he attained his reputation, but they are such only as every fashionable physician employs, viz. pleasing the patient, and avoiding every thing that can give uneasiness, till nature cures, or yields to the disease. He curtailed the rigorous abstinence of the Greek physicians, gave wine occasionally, recommended friction, gestation, baths, &c. vide *BALNEUM*, pro-

fessing to cure with speed, with safety, and without inconvenience. He declared that he deserved no credit, if he was himself unwell; and, fortunately for the credit of his system, he died in extreme old age, in consequence of a fall over the stairs.

Asclepiades was the founder of a new sect styled the *METHODIC*; for his philosophy was that of Democritus as reformed by Epicurus, and his physiology rested on corpuscles, flowing through invisible pores. The doctrine of Hippocrates, respecting the intelligence of nature, and her influence in curing diseases, he rejected with contempt. He denied even the power of attraction in the magnet. The soul he considered only as the united action of all the senses; and the intellect, or the power by which we understand what is secret or concealed, consisted, according to *Asclepiades*, in a resolution of the ideas, attained by the sensible images formerly collected. Every thing happened, in his opinion, from necessity, and nothing without a cause; nor was nature any thing but the body, or its motions, and, instead of assisting, usually injurious. Thus the Epicurean system of *Asclepiades* verged towards Stoicism. His anatomical knowledge was very imperfect, or he would not have thought that the urine passed from the intestines into the bladder through pores. Digestion was, in his opinion, unnecessary; and he supposed that the food was carried into the blood, and there attenuated till it was adapted to the pores of the vessels which conveyed it as nourishment. Hunger was induced by the relaxation of the larger, and thirst by that of the smaller pores. The fæces were not, he thought, excrementitious, as some insects fed on them.

His pathology was of a similar complexion. Inflammation was owing to obstruction either from the magnitude, the figure, the multitude, or the rapid motion of the atoms; pain to obstruction from particles of a large size, and the absence of the smaller ones. Faintings, dropsies, and hectic, arose from the too great size of the pores; and dropsies, in particular, he thought might be owing to the transudation of the flesh, which then became water. Quotidians were owing, in his opinion, to the obstruction of the larger particles, tertians of the less, and quartans of the least. He denied the existence of critical days.

This system he adorned with all the art of his former profession, and his practice was no less captivating. He rejected vomits and purgatives; admitted of bleeding, but with numerous limitations; and substituted, for purgatives, the most acrid clysters. Obstructions were, he thought, best removed by wine, by friction, gestation, and bathing. He plumed himself on having first directed frictions, and is minute in his directions for their management; yet, so far as we can collect from his disciples, he added little to what Hippocrates had, in a few words, directed. He sometimes, however, ordered medicines, though chiefly external applications, and occasionally scarifications.

Thus was this famous revolution in medicine effected, not from superior judgment, more extensive observation, or experience, but from ignorance of what former practitioners had taught, and indolence, which rendered him unwilling to learn. It was easier to construct a fanciful romance than to study by the midnight lamp, and some late systematics have thought the same. The whole was rendered fashionable by his eloquence,

and the comparative pleasantness of his medical directions.

We must not, however, suppose, as has been too common with medical historians, that Asclepiades had no prototype or rival. Celsus expressly remarks, that he borrowed from *Cleophantus*, a physician of a former era; and Pliny observes that the use of wine, as directed by Asclepiades, was borrowed from the same author, whose period is uncertain, though we approach it by finding that his scholar Mnemon flourished in the time of Ptolemy Evergetes. One sarcasm of his rivals has been mentioned, where he is referred to the butchers and cooks, as able to give him correcter physiological views than he possessed. Cicero also, the friend of Asclepiades, highly praises *Crateras*, and bitterly laments the death of *Alexion*. We may likewise mention, though it might more properly occur in another place, that *Crateras* the herbalist, highly commended by Pliny and Dioscorides was probably the first who drew figures of plants. He lived, however, in the time of Mithridates, and must be distinguished from a physician of the same name, the cotemporary of Hippocrates; nor is it too late to add, that many Asclepiades flourished in subsequent eras, whose works and opinions, without great care, may be confounded with those of the Bithynian.

The sect of Asclepiades seems not to have been at once established. *Alexander Philalethes*, his scholar, taught in Asia; and *Artorius*, the physician of Augustus, who perished at sea, Ab. U. C. 722, was also a follower of this celebrated innovator. Artorius has been confounded with Antonius Musa; but he had been dead ten years, when the latter succeeded in the cure of the emperor, after his former physician had failed. Who that physician was is not certainly known. If we trust the emendation of P. Harduin, he was called *Camellius*; and this name occurs not only on inscriptions preserved by Gruter, but on medals. What the disease of Augustus was we are not informed; probably a debilitated system, which A. Musa cured by cold bathing, cold drinks, and lettuces, which Camellius' scruples had forbidden. The gratitude of Augustus was unbounded. His pecuniary rewards were immense: he was allowed to wear the ring; and immunities were not only granted to him, but to all who exercised the same art. Suetonius adds, that his statue, made of brass, was placed next that of *Æsculapius*. We have no reason to suppose that Musa was a follower of Asclepiades; for he is spoken of by Galen as intimately acquainted with the whole science of medicine.

Whether it arose from the slow progress of the plans of Asclepiades, or from the alterations and improvements of *Themison*, that the latter has been considered as the founder of the methodic sect, is uncertain. Such, however, is the general language of medical history, and we must follow her steps. Themison has been highly commended by his cotemporaries and successors, and his name was long synonymous with that of an able physician. Yet we cannot but recollect the line of Juvenal:

Quot Themison agros autumno occiderat uno.

Asclepiades chiefly considered the causes of diseases: Themison thought it only necessary to connect them by some common symptom, and divided diseases into the stricta, laxa, and mixta. By these terms we must not understand, with the generality of authors, constricted

and relaxed fibres, or a mixture of both, but diseases attended with impeded or increased secretions, or too great discharges from one part, and too little from another. These principles afforded a *path* for physicians, and hence the sect (from *methodos*, via) was styled the methodic. In the first case he directs evacuants, in the second restringents, and in the third to oppose, by either class of remedies, the most dangerous disease. Such was the system he taught in advanced age; but the methodic doctrine had not yet been polished with care, so that we shall speak of Themison as an individual only in this place.

Themison neglected the precepts of Asclepiades in many respects, particularly in giving aloes and scammony, in allowing cold water after bleeding, and in not observing the due periods for giving nourishment, exciting evacuations, or bleeding. It is remarkable that in the writings of the methodic sect we find the first traces of bleeding with leeches; and Cælius Aurelianus relates a singular fact of Themison, that, having been bit by a mad animal, or possibly remaining too long with a friend labouring under an hydrophobia, he contracted the same disease. He cured himself; but, when he attempted to explain the method, he relapsed. This must have been a high degree of hypochondriasis. He was the author of many works, from which Cælius Aurelianus has preserved short extracts; but we can select nothing very important, except his praises of plantago, a plant supposed to be discovered by himself.

The system of Themison seems to have had no very violent opponent, or defendant: so far as we can collect, the opinions of physicians vibrated between the pores of Asclepiades, and the stricture or laxity of Themison, and practitioners seem to have reasoned with some freedom, though with no striking marks of genius or ability. A work intitled *Problemata Medica*, ascribed to *Cassius*, who seems to have lived about the end of the reign of Augustus, and the beginning of that of Tiberius, displays some marks of judgment and discrimination; but in his reasoning he seems to lean rather to the opinions of Asclepiades than Themison. We must not, however, conceal that the problems have been attributed to a later author, who is by no means a servile follower of the Rhetorician's doctrines. His practice, as we learn from Celsus, was far from irrational, and he freely gave cold water in fevers. Galen and Scribonius Largus mention a remedy of Cassius, called *colice*, as useful in colic pains. It consisted of carminatives, spices, opium, and saffron. This receipt Cassius left, apparently, to his servant Atimetus, whom he bequeathed to Tiberius, and from him Scribonius received it.

Celsus was another distinguished practitioner of the methodic sect, who brought, or greatly contributed to bring, physicians back to the patient study and observation recommended by Hippocrates. He seems to have been a cotemporary of Cassius; and his language alone would place him in the Augustan age. Some late critics have reduced him to that of Trajan. Pliny, however, who dedicates his work to Vespasian Titus, in his sixth consulship, A. U. 830, quotes passages of Celsus, which we still find in his writings; but Trajan only began to reign twenty years afterwards. Pliny also observes, that Julius Græcinus, respecting vineyards, transcribed the directions of Celsus; but J. Græcinus was murdered by Caligula, according to Tacitus,

and Caligula was himself killed in A. U. 783. Celsus tells us that Themison, in advanced life, had deviated from the precepts of Asclepiades, and Pliny, that Themison was the pupil of Asclepiades, who lived in the time of Pompey. Celsus, indeed, speaks of Themison as still alive, and consequently he must have himself flourished in the latter years of Augustus. Celsus is said to have been a Roman, or perhaps a Veronese; but though he speaks occasionally of his own observations, he was not a regular medical practitioner. Pliny never mentions him in this light; and, when he enumerates the physicians of Rome, the name of Celsus is not included.

Celsus in his medical works has chiefly followed Hippocrates, particularly in his Histories of Diseases and Prognostics, except in relation to critical days; but he is not, as has been supposed, the servile commentator of the Coan sage; for he quotes numerous authors of a later era, and seems to have given a brief abstract of the best systems, in a connected view, though evidently of the methodic sect, and the echo of Themison in what relates to the cure of fevers. He is, indeed, rather an epitome of his predecessor's maxims, than himself an object of historical research; and we shall leave him with remarking, that those who wish to study the opinions and practice of the ancient physicians will find both elegantly, as well as correctly, detailed in Celsus.

We should scarcely have mentioned *Æmilius Macer*, a physician of this era, who is said to have written on plants, on breeding birds, and on theriaca, but to remark that his works are lost, and that the poem on the Virtues of Plants, ascribed to him, is the production of an obscure monk of the middle ages, or, as has been said, of the physician Odo. Of *Servilius Democrates* we should also have scarcely spoken, since his era is uncertain, and the subject is too uninteresting to induce us to engage in the disquisition, but that the more laboured composition of the Mithridate and Theriaca is professedly taken from his works by Galen. They were detailed in Greek iambics. Of an uncertain age also is *Philo*, whose name is preserved in the Philonium, a preparation described, according to Galen, in elegiac verses. In this prescription the corrector of opium is the euphorbium, as in the theriaca it is the squill. He seems to speak of himself as of the family of Asclepiades; but his age, we have said, is doubtful.

Scribonius Largus, of whom we have incidentally spoken, was of an era posterior to that of Celsus, though not so late as has been suspected from his style; a peculiarity satisfactorily explained, by supposing that he wrote in Greek, and that his work was translated by an inferior author. His tract on the composition of medicines contains many choice receipts, collected from different sources, chiefly private collections, and empirical traditions, which are not found to countenance the encomia with which they are introduced. Scribonius highly commends his preceptor, *Apuleius Celsus*, whose antidote against the hydrophobia he has preserved. Another pharmacist of that era was *Philenides* or *Philonides*, who wrote, according to Dioscorides, on white hellebore; but the chief author in this department of medicine was *Andromachus*, perhaps the first who was dignified with the title of archiater, though the honour of priority has been contested in favour of Democrates. The title has been equally the subject of con-

troversy, and it has been disputed whether it meant the principal, or the emperor's physician. Galen, indeed, expressly observes, that such were his talents, not only in the medical but in the literary departments, that he was appointed ἀρχεῖν τῶν ἰατρῶν. He was the author of the theriaca, still known by his name, whose utility consisted not only in resisting the power of all poisons, but in giving calmness and hilarity, as well as removing the effects of fatigue. In this preparation the troches of vipers were designed to be the alexipharmic, and the opium the cordial, ingredient. This remedy, for more than one thousand five hundred years, enjoyed the highest reputation, and was prepared by kings and noblemen with the most accurate attention. The receipt in Greek verse is preserved by Galen. Andromachus has left no other memorial; but the works of his son are often quoted by Galen, though neglected by later authors, as he is not explicit respecting the preparation of his compositions, or the times of most successfully employing them.

Numerous are the collectors of formulæ in this period. Among these are the younger *Asclepiades*, called, probably for the sake of distinction, *Φαρμακίων*; *Charicles*, highly commended by Tacitus, and *Menebrates*, perhaps of an earlier era, who first endeavoured to abolish the medical characters of weights and measures, as liable to be mistaken by transcribers, and to substitute words. The improvement, however desirable, was soon overlooked, and Galen complains that the characters were again employed.

There is much reason to suppose, that, from the time of Celsus, physicians again returned to the more certain road of observation and sound reason; but either the rage of innovation, or the desire of distinction, excited another sectarist, who, like Asclepiades in a former, and Paracelsus in a later, era, attempted to overturn all that his predecessors had collected. This man was *Thessalus Trallianus*, who boastingly styled himself, on his tomb, latronice. His father was of the lowest rank, and Thessalus himself without the advantages of education. This is the account, indeed, of Galen, who, on every occasion, eagerly censures him; but we have the evidence of Pliny to convict him of the most disgusting arrogance, and the most consummate ignorance. He gained access to his superiors by flattery, and a subserviency to their pleasures; nor did he profess himself a physician till he had disgraced himself by every species of infamy in their service. His system differed, however, very little from that of Asclepiades and Themison. If, in their opinion, health consisted in the pores being adapted to the fluid, and disease in their being unsuitable, Thessalus thought the same. But in the mode of relief he aimed at changing the state of the solids rather than the fluids. He also was the first who in fever ordered three days abstinence and rest, from which physicians were afterwards called *diatritarii*. His peculiar pathological opinions introduced a singular language, which has not been properly explained, viz. *metasyncrasis* and *metasyncritical* remedies. In the language of the methodic sect, *συζυγίσις* is opposed to *διακρίσις*, the former meaning to mix and unite, the latter to separate. *Μετασυζυγίσις*, therefore, means the separation of bodies previously united. Cœlius Aurelianus uses the words *reincorporate* and *reincorporatio*. The chief works of

Thessalus, quoted by Cœlius Aurelianus, relate to diet; but Galen mentions his name on a subject of surgery, which leads us to suppose that he wrote some surgical tracts.

Among those who recommended themselves by the novelty of their fancies rather than their improvements, we may mention *Crinas*, of Marseilles, who only allowed food when the horoscope of the patient permitted; a system sarcastically hinted at by Juvenal; and *Charmis*, from the same city, who, with less discrimination and more eagerness than A. Musa, allowed only of cold baths and cold drinks. Authors of a superior character, in this era, were *Rufus Ephesius*, who was perhaps the first medical lexicographer, and who wrote *De Nominibus Partium*, and *Erotian*, whose *Lexicon Hippocraticum* is still a work of great value. Rufus, who is placed by some historians in the time of Trajan, wrote many other works, particularly one on the affections of the bladder. His poem, in hexameter verse, on plants, is wholly lost, unless, as has been suspected, the lines on the plants consecrated to the gods, added by Aldus to his edition of Dioscorides, and preserved in the Greek bibliotheca, be a part of it, as Fabricius suspects.

In this era also, from the age of Nero to that of Trajan, *Dioscorides* and *Pliny* lived. The vast work of the latter has furnished many parts of this history, and the *materia medica* is indebted to each author for the most important aid. We have mentioned them more particularly in another place. From the Preface to *Arius* it is probable that he was himself a practitioner of medicine, though to no great extent; and, from the predilection he seems to feel for the sect of Asclepiades, if we may guess from his almost exclusively quoting his followers, he was probably a Methodic.

It will be obvious, from this history, that the doctrine of the Methodics had, at no period, a very general currency, and about this time the Asclepiades were divided into many subordinate sects. One of these, the EPISYNTHETICS, endeavoured to reconcile the various discordant opinions of different authors; and another, the ECLECTICS, to select from each system what was most probable. The chief of the first was *Leonides of Alexandria*, whose works are lost, and from the quotations which remain in other authors, it is not easy to ascertain his peculiar opinions. The chief of the eclectics was *Archigenes of Aphamea*, a most excellent author, highly commended by Haller in all the different departments of medicine. He was a scholar of *Agathinus*, one of the chiefs of the Episynthetics.

Another sect into which the Methodics divided, and which was at last absorbed in, or absorbed, them, the PNEUMATIC, merits more particular notice. The chief of this sect was *Athenæus of Attalia*, a man whose system, according to Galen, was polished with greater skill than that of any of his cotemporaries. The philosophy of the Pneumatics was derived from the Porch, since they allowed Chrysippus to be their great prototype. Athenæus supposed that fire, air, water, and earth were not really elements, but that their qualities, heat, cold, dry, and moist, merited this title. Following the Stoics, he introduces a fifth principle, viz. a spirit governing and directing every thing, and occasionally, when offended, inducing diseases. From this new principle they were styled Pneumatics. Agathinus,

already mentioned among the Episynthetics, was in a subsequent period a Pneumatic, in consequence of his attending Athenæus. He explained, it appears, at some length, the principles of his sect, in a tract on Discoveries since the time of Themison. He wrote also on the pulse. *Herodotus*, *Archigenes*, and other physicians of character, were followers and pupils of Athenæus; but the fame of each was eclipsed by that of Aretæus. It is singular that he never mentions Galen, nor is mentioned by him; and, at the same time, the quotations of Ætius from Archigenes bear a considerable resemblance to the observations of Aretæus on the same subjects. Was the Attic dialect of Archigenes more agreeable to the Roman ear than the Ionic of Aretæus? or were they one and the same, differing only by a change of dialect? We must, for want of further information, leave this subject in its former obscurity.

The language of Aretæus is distinguished by a luminous terseness, which impresses the idea with considerable force. He can scarcely be styled a Methodic, and indeed bears few marks of that sect, and particularly differed from them in investigating the causes of diseases by anatomical dissections. The nerves, he supposed, did not run from their origin to their termination in straight lines, but crossed each other in the form of an X, passing in this way to different sides; and he thus explains the disease felt on the side opposite to that where the head was injured. His practice was that of the most judicious of the ancient physicians, and he was particularly fond of exciting vomiting by white hellebore. This operation, he remarked, relieves the breathing, changes what was of a bad colour to a good one, and restores plumpness to those who were emaciated. He used the most active purgatives, bled frequently and freely from different parts, though he argues very forcibly against the refinement of some practitioners, who prefer small veins, which are the branches only of those from which blood is usually taken. He employed arteriotomy, cupping glasses, and leeches; but preferred curing acute diseases by diet. He gave wine more freely than former physicians allowed, and employed opiates with little reserve. He was peculiarly partial to castor, as a nervous and antispasmodic medicine, thinking it also an assistant of digestion. He recommended asses', mares', sheeps', and women's milk, used frictions and the actual cautery, and advised the operation of lithotomy. In short, practitioners of any age will derive from Aretæus the most sagacious and useful medical observations. His practice is active, enlightened, and discriminated. Aretæus is, by some authors, referred to the age of Nero. His era is, indeed, uncertain; but the Ionic dialect was not wholly disused even in the time of Hadrian.

An author of this era, and of the Methodic sect, whose works are lost, was *Soranus* of Ephesus; and we have reason to regret it, because Galen, who loses no opportunity of criticizing the Methodics, speaks respectfully of Soranus. They were translated in a barbarous style by Cœlius Aurelianus, an African; but even in this dress they have reached us in an imperfect state. Yet from Cœlius we have the only systematic and connected view of the Methodic doctrine; for by Soranus only it was brought to a perfect state. As the cycles of the Methodics are often mentioned in medical works, we shall add a short description of the meaning.

The cycles were periods supposed to consist of three days each, or combinations of three, and during these the same plans were continued; but at the end of each cycle the exertions were increased, so as at last to rise to the most active measures. The resumptive cycle consisted of common foods: the metasyncritic of a more acrid and stimulating diet, with frictions, baths, rubefacients, sternutatories, &c. The cyclus vomitorius was distinguished into two, as the vomits accompanied the sparer diet of the first, or the more stimulating diet of the second. Each cycle consisted of four diatri, though sometimes prolonged to sixteen days; the additional diatri containing four days.

We have already observed, that in all the wanderings of the fancy, the natural good sense of physicians occasionally brought them back to the safer road of patient thinking, and accurate observation, which so much distinguished the Hippocratic school, the real *μεθοδος* of the healing art: but we have now to notice the revolution which for ages gave a stability to the science of medicine, and fixed an oracle, who for more than one thousand five hundred years dictated to the world, and whose decisions were listened to with the most implicit deference. We allude to CLAUDIUS GALENUS, of Pergamus. Galen lived in the second century of the Christian era, and was born during the reign of Severus. He studied at Alexandria, but chiefly practised at Rome, and was the physician of the amiable and benevolent Marcus Aurelius, one of the few emperors who added lustre to the purple. Galen was distinguished in his earliest years, for a lively fancy and uncommon ingenuity. He attained all the learning of that era, and was soon disgusted with the prevailing systems of medicine. He professed, indeed, to select from each what was most valuable; but has almost exclusively confined himself to commenting on and illustrating the works of Hippocrates, which he thinks succeeding physicians had either misunderstood or misrepresented. Yet he seems to have taken the qualities of the four elements from Athenæus; and though Hippocrates mentions, somewhat equivocally, the Spirit, he apparently borrows the vital, animal, and natural spirit from the Pneumatics. Galen wrote very diffusely on every part of medicine; but he added only dress and ornament to the system of Hippocrates. In fact, minute distinctions, refined speculations, and abstract reasoning are the whole for which the medical world is indebted to him. They did not lead Galen himself from the path of truth; but they had the most fatal influence on his successors, who speculated when they should have observed, and reasoned when they should have acted. The doctrine of concoction, the most fatal idea which ever occurred, was completely established in the school of Galen.

The splendour of Galen's fame dazzled his cotemporaries and successors, so that we find few who afterwards dared to think beyond his circle. *Quintus Serenus Samonicus* wrote, in Latin verse, on medicine in the following century; but whether that was the work of the father or the son is still doubtful; nor does its real merit call on us to enlarge on it. *Alexander Aphrodisæus*, who wrote a treatise on fevers, and a work intitled *Interdicta Medica*, and *Problematica Physica*, scarcely deserves more attention. *Oribasius* has been styled the ape of Galen. The twenty-fourth and twenty-fifth books contain, indeed, an abridgment of

Galen's anatomy; but we find a description of the salivary glands, which, if known to the Pergamene, has never reached us in any of his works. *Oribasius*, who lived till near the latter end of the fourth century, was the physician of Julian, and his collections were completed about the year 360. It is not, however, true that he collected from Galen only; for even in his first fifteen books, the only ones we possess, except the anatomical ones, other authors are mentioned, and we find numerous quotations from preceding physicians. *Oribasius* was not only a physician, but high in the confidence of the emperor Julian, who appointed him the Quæstor of Constantinople; and though in the succeeding reign he was for a time disgraced, and even banished, his real merits were too considerable to admit of the continuance of his exile.

His anatomy, we have observed, was copied from Galen; but the remaining books of his medical collections, amounting, it is said, in the whole to seventy-two, besides his quotations from authors now lost, contain some practical remarks of importance. His recommendation of scarifications, instead of cupping, is not, we think, one of these; for ligatures, bathing the legs, and the application of stimulants previous to the use of the lancet or needle, answered the same purpose as the rarefaction or exhaustion of the air.

Oribasius first described the singular madness styled *Λυκανθρωπία*, in which the patients avoid the society of mankind, haunting the most desolate places, and wounding themselves with stones, &c. Some critical disquisitions have been employed to determine whether they "open" the tombs, or only "dwell" among them. The question is of little importance, though, as it is confessedly the disease mentioned in the New Testament, if we recollect rightly, the possessed are there said to "come out of the tombs exceeding fierce;" and the tombs of the pagans were generally open to receive the oblations to the manes of the deceased. As we have pronounced the question to be a trifling one, we shall not enlarge on it. *Oribasius* wrote four books also on diseases, and several others, which were chiefly abridgments of Galen. Some receipts, quoted by *Ætius*, seem to be his own; but the commentaries on the aphorisms of Hippocrates, attributed to him, are of a much later era. Excepting the collections, the nine books of his synopsis, addressed to the younger Eustathius, and four, *De Euporistis*, to Eunapius, are the only works which remain of this author, who certainly merits more attention than he has received.

About the same era *Nemesius*, bishop of Emesa, abridged the physiology of Galen, intitled *Natura Hominis*. *Vindicianus*, the archiater of Valentinian, addressed to that emperor his *Carmen Epistolare*; and *Theodore Priscian*, the disciple of *Vindicianus*, and archiater to the second Valentinian, wrote his four books *De Curatione Morborum*. The last work has been attributed to *Q. Octavius Horatianus*, the disciple of *Priscian*, and under his name the treatise is annexed to the Strasburg edition of *Albucasis' Surgery*. Several authors of this century, whose works are still extant, merit little more than the mention of their names. The chief is *Marcellus Empiricus*, who wrote *De Medicamentis Empiricis*; *Plinius Valerianus*, whose work *De Re Medica* is referred by *Gunzius* to *Siberius*; *Vegelius Renatus*, a different person from the *Tactician*;

and *Calius Aurelianus*, already noticed, the last medical author who wrote in Latin.

After the lapse of nearly one hundred years, in which scarcely the name of a physician is recorded, we meet with *Ætius of Amida*, of whose sixteen books (iv tetra-biblia) but eight have yet been published in Greek, though we possess the Latin version of the whole. He is chiefly distinguished as an original writer, by his chiro-surgical operations, and in this line his practice seems to have been extensive. In medicine he recommends punctures in dropsies; but the observations on these subjects are taken from Archigenes and Leonides. His remarks on cauteries, both actual and potential, are more peculiarly his own. He advises them freely in many complaints, and directs numerous drains to be made. To keep these open by tents seems to have been the improvement of a subsequent era; for in many places where caustics are recommended by *Ætius*, tents could not be used. Setons are only mentioned 800 years afterwards. From Leonides he also describes the *dracunculi*, by modern authors called the *venæ medinenses*, an appellation given by the Arabians. *Ætius*, who had studied at Alexandria, introduced much of the Egyptian pharmacy, and was particularly fond of external applications. He introduced also charms and amulets, so common in the same country; and, though a Christian, and an officer of the emperor's household, seems not to have been exempt from credulity. Many boasted and high priced remedies he has taught us to prepare; but adds no opinion of their utility, though of other medicines, and indeed generally of those truly valuable, his encomia are usually warm.

Palladius of Alexandria was but a few years later than *Ætius*, and his Synopsis of Fevers, as well as his Commentaries on different parts of Hippocrates, are still extant. He differs, however, little from the system of Galen, and merits no particular notice.

Alexander Trallian, so called from his native place, Tralles, a city in Lydia, was nearly of the same era, and a writer more original than any that have occurred to us since the days of Galen. He limits his observations to the signs of diseases and their remedies; and though he shows too great confidence in the efficacy of some apparently trifling medicines, and is particularly fond of amulets; yet, in many parts of his work, he displays great judgment, and extensive experience. His observations on bleeding in syncope are valuable, and those on the use of emetics, particularly of purgatives in fevers, highly useful. He is apparently the first author who mentions rhubarb; but he certainly means the Rhapontic, as he speaks of it only as an astringent. The white hellebore had at this period been neglected, and even Alexander speaks slightly of it: nor was it again recommended till *Asclepiades*, more than fifty years afterwards, employed it with success. Alexander was by no means a servile follower of Galen. On the contrary, he frequently differs from him, and in some instances, particularly the treatment of hectic, boldly pronounces him wrong.

Though Christianity was now established, and the physicians lately mentioned were Christians, yet the next author was the first monk who wrote on, and probably practised, medicine. We shall call him *Theophilus*, though, from his sanctity or his talents, he was also

called *Philotheus* and *Philaretus*. There is, however, a singular confusion arising from the name of Theophilus, which was given to a cotemporary of Alexander, called by him *Jacobus Psychrestus*, or *Psychochrestus*. The latter was by birth an Alexandrian, archiater to Leo the Thracian, and a count of the empire. If they were, therefore, the same, he must have become a monk in his latter years, a circumstance by no means uncommon. Jacobus Psychrestus left apparently behind him no medical work, though Theophilus, who by some historians is placed in the beginning of the seventh century, and certainly a different person, is the author of five books *De Fabrica*, in the collection of Celsus Crassus, and a tract *De Urinis*, the first work professedly on the subject, in Henry Stephens' *Principes*. His scholar, *Stephen of Athens*, was the author of a Commentary on some part of Galen's works.

Paulus of Ægina is the last author that claims our particular attention. He flourished near the end of the seventh century, and was the first physician who, by his particular notice of female diseases, appears to have paid very particular attention to them: indeed he seems to have practised midwifery. In medicine he does not merit any great regard; but his surgical observations are valuable, and often new. What relates to lithotomy and herniæ are the most important parts; but the observations on aneurisms are sometimes new, and generally valuable.

Some Byzantine physicians, dimly seen through the obscurity of the darker ages, we may shortly mention. *Nonus*, who lived near the end of the tenth century, by the command of Constantine Porphyrogenetus, wrote an Epitome of Medicine, chiefly taken from *Ætius*, Alexander, and Paulus; and near a hundred and fifty years afterwards, *Symeon Lethius*, who held some office in the palace of Antiochus, wrote a Syntigma de Ciba-rorum Facultate, in which he copied chiefly the work of *Psellus*, who was his cotemporary. Both treatises still remain, but are of little value. Demetrius Pepagomenus, near the end of the thirteenth century, was a distinguished author on hawking; but he was the physician of Michaelis Palæologus, and left also a Treatise on Gout. Somewhat later lived *Myrcpsus*, the author of the *Antidotarium*; and the scene closes with John, the son of Zachariah, honoured with the title of *Actuarius*, nearly answering to what we mean by physician in ordinary, in the court of Andronicus Palæologus. His six books on the Methodos Medendi, and his Treatise *De Urinis*, have been commended by some practical authors; and the latter was thought, by H. Stephens, worthy of a place, in his valuable work, among the *Principes Artis Medicæ*. All his works are in a great measure compilations from his predecessors, but there are some original observations respecting the palpitation of the heart, in which Actuarius seems first to have recommended bleeding and purging. He is also the only Greek physician who speaks of the milder purgatives, as senna, manna, cassia, and myrobolans. The pods of the senna were then only employed, and it was brought from Syria under the name of a fruit. These medicines were professedly borrowed from the Arabians, whom he calls barbarians. He mentions sugar, also, and what seems to have been distilled water of roses, derived from the same source. Indeed

distillation appears to have been known prior to the era of Actuarius, which was probably about the end of the eleventh century.

We have greatly regretted, in this long career of the Grecian medicine, that no author has connected the revolutions of this science with those of the Grecian philosophy. We perceive, in every step, how greatly they would illustrate each other; and, but for the extent to which our article would be thus drawn, we should have enlarged a little on the connection. We have, in this part of our history, traced, with anxious care, the succession of the different sects, the influence of prevailing opinions, their alternate fashion or decline, and while these, with some neglected portions of the history, have detained us, we have certainly omitted, not without design, what may be found in every common author. We ought not to conceal that the history of medicine has not hitherto been that of a science. We have seen the scattered limbs: we wished to see them connected, so as to form an entire body; and of this connection we have endeavoured to give the outline.

While we have less anxiously detailed the medical opinions of philosophers, we must not omit some observations of Dr. Friend, whose history is chiefly filled with discussions on different portions of ancient medicine. He remarks, that the historian Procopius was probably a physician, from his minute and scientific description of wounds, and of the plague. He adds, too, that the professional character of St. Luke is obvious, not only from his more polished language, but from his expressions relating to diseases. The curiosity of the subject has led us to pursue it, and we certainly find, in the relations of the cures effected by the miraculous power of our Saviour, the elegant terseness of Aretæus.

When science declined in the west it again rose in the east. In pursuance of the plan just mentioned, we have not omitted to notice the gradual steps by which medical knowledge gradually approached its former cradle, seeking, in its decline, the protection it had received in its commencement. In the later ages of Grecian medicine we perceive a strong predilection for an education at Alexandria, and we have already traced its progress in Asia, as we catch transitory glances of its occasional appearance. Alexandria, once the receptacle of the famous library, burnt by accident during Cæsar's attack, received, in return, by the bounty of Anthony, the famous collection of Mithridates, already mentioned as a legacy to the Roman people; and even at the commencement of the ninth century its professors were highly celebrated. Other circumstances favoured the progress of medicine in the east. When Valerian was conquered by Sapor, the king of the Persians, and carried captive to his new city, Grandisapora, he was followed by many Greek physicians. So early as the sixth century a medical school was founded in that city, and an hospital established in it. Hospitals were, indeed, not unknown in the latter ages of the Roman empire, and seem to have been first established before the reign of Justinian. Its school was highly celebrated, and much frequented by the Arabian physicians, even at the time of Mahomet; but Persia was conquered by the Saracens in the year 460, and medicine was scattered by their means through the wide extent of their tributary regions, even to the confines of Spain. Previous, how-

ever, to the conquest of Valens, Sapor had married the daughter of the emperor Aurelian, and probably the medical knowledge of Greece had already attracted the attention of the Persians. They left, indeed, no traces of their acquisitions; for the earliest eastern medical authors were Syrians. *Aaron*, the presbyter first collected what he called the Pandects of Medicine, from the Greek, about the time of Mahomet, A. C. 622, which were only translated into Arabic by Masegawaihus, in 683. Near a century afterwards we find Alexander, the second caliph of the house of Abbas, requiring the assistance of *Bactishua*, who resided at Grandisapora; so that this city still retained its character for the acquisition of medical science, and the family of Bactishua continued famous for many succeeding generations. To them the eastern nations were indebted for many translations of the Grecian authors into Syriac and Arabic.

All these translations, and even *Honain's*, were very imperfectly executed, though the latter, disgusted by the treatment of Mesue, had retired two years to the Grecian islands, where he had cultivated his knowledge of their language. Indeed, on all occasions the Arabians take the liberty of altering the arrangement, and often the sense, of the Greek authors, so that they can scarcely be recognised in their new forms. The names of plants are also so much changed, that many are, at present, unknown.

Mesue was the first author, after Aaron, who wrote on medicine. He also is styled a Syrian, as he probably wrote in the Syriac language, and was apparently educated under one of the descendants of Bactishua. Yet, when we compare his works which now remain with the criticisms of Haly Abbas, we are obliged to remove him to a later date, or admit, with the best historians, that there were two or more of that name, of very different periods.

Serapion seems to have been next in succession to Mesue, and was probably the first medical author who wrote in Arabic. Historians have differed also about his era, and the knot, as usual, has been cut, by supposing that there were other authors of this name; for Serapion is only a Patronymic; but Haly Abbas, who wrote near his time, quotes his works as they have been handed down, and places him between Mesue and Rhazes. In other respects he merits little attention.

Rhazes, the great luminary of the Arabians, flourished about the middle of the tenth century. To him it is supposed that we are indebted for the first description of the small pox; and, in fact, he is the first author on this subject which has reached us, though we are informed that it was publicly described by a preceding physician, *Amrou*. The two great works of Rhazes are the *Continet*, and the ten books styled *Almanzor*, addressed to Mansor, king of the Corassini. The first appears rather a common place book, in which facts and observations are obscurely noticed for his own recollection. The second is a full and complete view of medical science, taken almost exclusively from the Greek physicians. Rhazes, however, was the first author who spoke professedly of the diseases of children, and he first described the spina ventosa. The Arabians are said to have been the earliest physicians who applied chemistry to medicine, and chemical remedies have been attributed to Avicenna. We were therefore anxious to

point out the early traces of this connection in the Greek authors; and Rhazes certainly, in many instances, spoke of chemical preparations.

Haly Abbas, or Haly, the son of Abbas, we have already mentioned. His only work is styled *Almaleki*, or the Whole Book of Medicine. One half of this work is theoretical, and the other practical. Haly, however, is chiefly valuable for his remarks and criticisms on Mesue, Serapion, and Rhazes. Liberal in his censures on others, he has added nothing from himself to the stock.

Avicenna is the most celebrated author of the Arabians. He flourished early in the eleventh century, and was born at Bockara, in Chorasán. He was the last of the Arabian authors of medicine; for his successors were born in Spain, where the Saracens were then triumphant, and little communication seems to have been held between the eastern and western empire. Avicenna has, however, little of his own: he was merely a compiler, though his chief work, his Canon, was for centuries commented on, and the syllabus or foundation of the lectures in every university. Of *Albucasis*, undoubtedly the same author who is sometimes styled *Alzaharavi*, we have already spoken in the history of surgery. It is, therefore, only necessary to mention him, as it preserves the connection with the Arabian authors, and to add, that he flourished near the end of the eleventh century.

Avenzoar, or the son of Zohr, was an Arabian of the western empire, born at Sevil, in Spain, apparently about the beginning of the twelfth century. He lived to the very advanced age of a hundred and thirty-five, and continued his practice to the last, from which he has been called *Experientator*. The term probably implies the *experienced*; for he deserves not the title of *empiric*, which, in the opinion of some authors, this term implies. He treats of medicine in a rational, often in a dogmatic, manner, and seems first to have described the inflammation of the mediastinum, and of the pericardium, as well as the dropsy and empyema of the pericardium. It is a singular remark, that he cannot follow Galen's advice in giving asses' milk in consumptive cases, as it is unlawful for the Saracens to drink the milk or eat the flesh of this animal, and that he, therefore, substituted goat's milk. It is only, however, to the stricter sects of Mahometans that the ass is an abomination; but this circumstance may account for the use of goat's milk. He first recommended the bezoar, and seems to have been particularly expert as a surgeon. From some parts of his works we should even suspect that he had dissected dead bodies. In his time, surgery, pharmacy, and medicine, seem to have been practised by different persons, and neither Avenzoar nor Averhoes quotes the Arabian physicians of the east. The little connection between the Arabians of the east and west seems to have been owing to a political, or rather a religious, dissention respecting the true caliph.

Averhoes was also a Spaniard, who flourished early in the thirteenth century; but rather distinguished for his Commentary on Aristotle than for his medical writings. His *Compendium Medicinæ*, however, in seven books, has been highly commended by some authors.

Mose Ben Maimon, a scholar and a cotemporary of Averhoes, was born at Corduba; and, though a Jew, was archiater of Saladin, the sultan of Egypt. He was

the author of a Treatise on Regimen, addressed to the sultan of Babylon, and of Aphorisms, according to the Doctrines of Hippocrates and Galen.

The works of some other Arabian authors are extant, particularly of *Abenguefit*, *Bulcasen*, *Jesu Haly*, *Camanusali*, &c.; but we cannot find that they contain any thing peculiarly interesting to the progress of the science. Indeed, during its cultivation in the east, we find little added to the stock. The Arabians certainly introduced many new medicines, made some additional progress in medical chemistry, and mitigated the severity of the Grecian practice. The new diseases, which they described, are few. The small pox was a native of the east, and the others were in no respect highly important. They seem, therefore, to have cherished, and but slightly to have animated, the spark. The Arabian writers refine, indeed, with great fancy, and distinguish with the most minute precision; but their metaphorical and ornamented language they have wisely left to their poets. Perhaps, from the example of their Grecian masters, they are often concise, and generally reason with correctness and precision.

Thus while medicine was declining in Greece it was kept alive in Arabia; but it seems scarcely to have survived the thirteenth century in either. This was the period of its downfall. Europe and Asia were obscured by the cloud of ignorance, and the arts of war or poetry were alone cultivated. European genius began first to penetrate the obscurity; but in this cloud of barbarity we for a long time catch but a few imperfect rays. As we found medical science stealing by almost imperceptible steps from Greece to Asia, so we shall here perceive, that, from the western extremity of the extensive empire of the Saracens, it gradually expanded to different parts of Europe. It is too much the fashion to refer the spread of knowledge to the Crusades. The human mind wants not such a powerful momentum: the gradual expansion of its own powers will solve the problem. The short distance from Spain to Italy, and the constant intercourse, even at this time, gradually introduced the medical knowledge of the Arabians to the latter country. It has been supposed that Latin, Hebrew, and Arabic professors of medicine were settled at Salernum in the seventh century. This opinion has, however, no well founded support; but it must have attained some credit, as a school, before 802, when Charlemagne founded a college there. It will be obvious, however, that, at this period, medicine could have gained little from the Arabian authors, since they were then imperfectly known even in the east; so that if, in reality, Salernum was so early a school of medicine, it must have gleaned the little knowledge it possessed from the later Grecians and the Byzantine authors. We are consequently ready to deny this early antiquity of Salernum as a seminary of medicine, and the more willingly, as its first author, *Constantine the Carthaginian*, flourished only at the end of the eleventh century. He did not collect all the accumulating science of this establishment of Charles the Great, but is expressly said to have resided, for a long period of his life, in Babylon and Bagdat. He was appointed secretary to Robert Guiscard, duke of Apulia, about the middle of the eleventh century; and there is much reason to believe that Salernum was established as a medical school about that time. Its appellation, *Civitas*

Hippocratica, shows that it was considered to be a scion of the Grecian stock; and, however barbarous the Latin style of the African may appear, it is said that he was intimately acquainted with Greek. He was afterwards a monk of Mount Cassino, thence called Cassinus, and dedicated his work, *Breviarium dictum Viaticum*, to its abbot, Desiderius, raised afterwards to the purple by the name of Victor the Third. Several other works, particularly the *Antidotarium*, and the *Loci Communes*, were written by him; but the substance is copied from the Greek and Arabian authors: the latter is apparently a servile translation of the work of Haly Abbas, though professedly an original, and, as he remarked, greatly wanted. The *Schola Salertina*, a Treatise on Diet and Medicine, in Leonine verses, was probably composed very early in the twelfth century, and was for a long period highly celebrated. It is said to have been written by John of Milan, and was dedicated to the duke of Normandy, son of the conqueror.

Salernum perhaps justly boasts of its priority as a medical seminary, and the school of Montpellier is the next, the foundation of which Astruc, in his memoirs on this subject, refers to 1150. That of Paris was founded, according to Naudæus, by papal authority, in 1220, and the school of Bologna in the following century. To this chronological series there is but one objection, that *Ægidius*, whose Latin hexameters on the *Virtues of Medicines, the Urine, and Pulse*, written towards the close of the twelfth century, is somewhat severe in his reflections on those who were educated at Montpellier; a circumstance which must have arisen, if the dates admitted, from personal opposition, as the character of the school could not have been, at so early a period, ascertained.

Few, however, were the physicians of character educated in these seminaries. One road to fame and fortune was obstructed; for the chief physicians of kings and princes were Jews; nor was the intolerance of the Spaniards so rigid as to reject this nation when their own lives and healths were in danger. The emperor Frederick II. attempted to restore the study of anatomy. In his Treatise on Hawking he introduced several valuable remarks on comparative anatomy, and instituted public dissections and demonstrations. Fifty years after this attempt, his laudable career was checked, in 1300, by a bull of pope Boniface, who forbade the dissection and preparation of the human body. To this edict Mundinus alludes, when he declines a demonstration of the internal parts of the ear; because it is necessary to separate the bones by boiling, which "*propter peccatum dimittere consuevi.*" Mundinus was an anatomist and a physician of considerable celebrity: indeed, so great was his credit, that any observations on the structure of the body, which did not coincide with his, were supposed to relate to *lusus naturæ*.

Arnold of Villanova and *Peter Julian the Spaniard* (afterwards pope John XXI.) were both celebrated for their knowledge of medicine, about the end of the thirteenth century. The former has been chiefly commended for his chemical knowledge; but, though none of his works remain, it is certain that he was not less famous as a practical physician. The latter was the author of several works, both physiological and practical; but all are copied from the Arabian or the Greek authors.

Gordonus, a Scotchman, was professor at Montpellier

early in the fourteenth century, and his system of the practice of medicine, entitled *Lilium Medicum*, contains some remedies not yet wholly forgotten. These are the troches, which still bear his name, and the *pulvis ad guttetam*. *Petrus de Apono*, an author of the same era, was one of the first professors in the university of Padua, then recently established. His chief credit was derived from his chemical remedies, of which very few were invented by himself. He practised at Bologna, and attained a high degree of reputation, with a handsome fortune. Apono commenced a supplement to *Mesue*, which *Francis of Piedmont*, in the service of Robert, king of Naples, continued.

Another physician in the service of Robert was *Johannes Sylvaticus*, styled *Pandectarius*, from his *Pandects*, or Medical Vocabulary. He was a Mantuan by birth, and educated in the school of Salernum; but his *Pandects* are written in so singular a style that they contribute little to their professed object, the explanation of the Greek and Arabian authors, and actually require a dictionary to explain them.

Nichol. Nicolus de Falconius, a Florentine, was nearly a century later, and must be distinguished from *Nicholaus*, a Florentine also, but of a later date, a celebrated patron of science. He appears to have been a physician of no common genius and learning; but his most distinguished work is his *Sermones Medicinales*, published at Venice, in four volumes, folio. The last author we shall mention is *Valescus de Tarenta*, who has given a compendious view of the doctrines of the Arabians, and of the physicians of the middle ages. He lived in the fifteenth century, and is one of the few authors who give opinions of their own. He appears to have been an able and experienced physician.

During this obscurity, Greece still retained her former treasures, and could boast of a few physicians to whom they were not unknown, and by whom they were not neglected. A warlike race, whose martial spirit was aided by enthusiasm, burst at once from its fastnesses, and soon overwhelmed the Roman empire in the east. The Turkish emperor, Amurath, in the year 1430, took by storm Thessalonica, from whence *Theodore Gaza*, a man of considerable learning, escaped, with some of his literary treasures to Italy. When Constantinople was taken, a few years afterwards, and the Byzantine kingdom wholly overturned, many others followed his example. All were warmly received by *Lorenzo de Medicis*, and the manuscripts, thus rescued from oblivion, soon disseminated the stores of Grecian poetry, history, philosophy, and medicine. The human mind was roused from its lethargy by many other events in this century. The invention of printing facilitated the communication of knowledge. *Colon* and *De Gama* discovered, or facilitated, the access to either India, from whence the *materia medica* gained new acquisitions. The Scurvy, first observed in Germany, in 1482; the *Sudor Anglicanus*, first noticed about the same time, followed by the *Lues Venerea*, and the *Morbus Petechialis* in Italy, equally animated the spirit of enquiry to prevent or relieve the effects of such afflicting scourges. During this era *Fracastorius* and *Massa* were the chief luminaries of the Italian schools; *Sylvius* and *Fernelius* of the Paris; *Lommius*, the excellent author of the *Observationes Medicinales*, was a disciple of *Fernelius*, and practised at Brussels. All these authors were warm

admirers of the Hippocratic medicine, and with equal zeal and perseverance endeavoured to revive it. *Botallus*, a Piedmontese of this era, a disciple of Fernelius, archiater to Charles IX. and Henry II. of France, chiefly distinguished himself by his recommendation of profuse-bleeding. In this practice he might have found examples both in the medical authors of Greece and Arabia; but evacuations, so indiscriminate and profuse, must be often injurious. The fatal effects of his plans are even yet felt; for, in France, venesection, almost forgotten in England, is still freely and copiously practised. *Duretus*, *N. Piso*, and *Hollerius*, were also French physicians, but with more correct views, under the guidance of Hippocrates, whom they admired and illustrated. *De Gorris* (*Gorraeus*) and *Fæsius* of Dijon were equally able illustrators of the ancients in the *Definitiones Medicæ et Oeconomia Hippocratis*; but the most striking features in the history of this era are the attention paid to prognostics, and the publication of select observations and consultations. For the latter we are indebted to *Forestus* and *C. Piso*.

As we approach nearer our own times, we shall pass more hastily on; and, as we have explained in distinct articles the prevailing systems of medicine, we shall connect only the historical links, except where we find any important fact omitted or misrepresented. The extravagant and erring spirit which we have in this history so often found expatiating beyond the sphere of sober investigation and patient observation, seems again to wander in the 17th century. In its commencement, indeed, *Bellonius* and *Riverius* still pursued the system of Hippocrates; and though *Sennertus* endeavoured to unite the doctrines of the Coan school with the more judicious parts of the chemical system which then began to prevail, it was reserved for *Van Helmont* to inundate the whole science with the mysticism of the alchemical doctrines and language. *Paracelsus*, who first introduced chemistry into medicine, was an ignorant boaster, the Jatronic of modern eras, professing to cure all diseases by chemical remedies. He burnt, in solemn state, the works of the ancients, as no longer necessary; and, in possession of the universal medicine to secure immortality, died himself in an hospital at the age of forty-seven. He lived near the middle of the 16th century, but then appeared like a single transitory meteor, so that we reserved any notice of his extravagancies till we could combine the whole of the chemical sect. *Van Helmont*, the next in succession, was a man of superior talents, distinguished by sagacity and judgment, which might have been more advantageously directed, but which still render his works, collected by his son, not unworthy the attention of the modern physician. He is considered as the first discoverer of factitious air, to which he gave the name of gas; but *Rey* had published, somewhat earlier, essays on the cause of the increase of weight in lead when calcined. His son was more mystical than the father, but acute and ingenious, and the friend of *Leibnitz*. He was succeeded as a chemical pathologist by *Sylvius de la Boe*, whose doctrines of alkalis, acids, and effervescence, even to our own time, disgraced the science. The prevalence of the chemical system, in the school of *Leyden*, probably led *Boerhaave* to select some portion of *Sylvius*' doctrine to fill up his eclectic system; and *Hoffman*, amidst more judicious and scientific views, returns often

with a partial fondness to acids, alkalis, and acrimony. In our own times the chemical doctrines infected *Willis* and the whole tribe of *Boerhaavians*; nor are we, at this moment, exempted from the mania, under the more fashionable names of oxygenation and deoxy-generation.

This century was, however, distinguished by exertions more honourable for science. It was the era of the discovery of the circulation of the blood, a subject already noticed, and of the dissections of animals, to ascertain many important points of physiology. In both *HARVEY* was a distinguished and active philosopher; and, while the circulation was decried or opposed by ignorance or prejudice, his other labours were warmly received. *Spigelius*, *Sanctorius*, *Asellius*, *Pecquet*, the two *Bartholines*, and *Rolfincius*, equally promoted physiology, or disseminated the discoveries of others, obtained by their dissections, assisted by the newly discovered art of injections, and the use of lenses; for microscopes, in the complex sense now affixed to the term, were the invention of the following century.

Another distinguishing and honourable feature of this century was the institution of medical and philosophical societies. Our own Royal Society was the first of these, and it was followed by the Academy of Sciences at Paris in 1667, established by the judicious and penetrating *Colbert*. The *Academia Naturæ Curiosorum* was at first a private society, and its origin is traced from 1652; but it was established, some years afterwards, by the authority of the emperor *Leopold*, and then styled *Academia Cæsareo-Leopoldina*. Its publications were continued, under various titles, till within these few years. It will fill but a small space to pursue this subject. The Royal Society at Berlin was founded in 1700 by the advice of *Leibnitz*, and first published its transactions (*Miscellanea Berolinensia*) in 1710; the Petersburg Academy in 1724, which first published its "Commentarii" in 1726; the Bologna Society, founded by *Marsigli*, first published its "Commentaries" in 1731. The Breslaw collection, afterwards called *Commercium Noricum*, was published from 1717 to 1731, under the former title; and from that time to 1745, under the direction of *Dr. Trew*, distinguished by the latter. The Royal Society of Norway began to publish their transactions in 1771; of Denmark, in 1745; and the Royal Academy of Sweden in 1739: the Royal Society at Upsal in 1720; of Basil in 1751; of Gottingen in 1752; and of Montpellier in 1766. Within the years 1771 and 1792 we have seen philosophical societies established in Hesse, Philadelphia, Brussels, Boston, Ireland, Padua, Edinburgh, Calcutta, and New York. These have admitted into their plan medicine as a branch of natural philosophy, and several medical improvements of importance have been published in their successive volumes. Establishments more closely connected with medicine are also numerous. The first work of this kind was *Thomas Bartholine's Cista Medica Hafniensis*, in 1662; and a similar one appeared in 1679, at Paris, entitled *New Discoveries in every part of Medicine* by *Nicholas de Blegny*. The *Zodiacus Medico Gallicus*, in Latin, by *Bonnet*, succeeded in the following year at Geneva; and in the same year, the lexicographer *Blanchard* published, in Holland, *Collectanea Physico-Medico*. The *Recueil Periodique d'Observations de Medicine* appeared at Paris in 1754, and was continued

under the title of *Journal de Medecine*; but this collection was preceded by the *Medical Essays of Edinburgh*, which were begun in 1733, and continued to 1742. These were succeeded by three volumes on a more extensive plan, entitled *Essays and Observations Physical and Literary*, and by the *Medical Commentaries of Dr. Duncan*. Two volumes of a collection entitled *Acta Medicorum Suecicorum* have appeared, which are not, however, exclusively medical, and two volumes of collections of a medical society at Copenhagen. The Royal Medical Society at Paris published their first volume at Paris in 1779, and continued their volumes, at irregular intervals, till the year 1788. Four societies have collected medical observations in London; the college who published their first volume in 1768, and their third in 1785; a society who published "*Medical Observations and Enquiries*" in six volumes, from 1757 to 1784; another society, to whom we are indebted for "*Medical Communications*," of which two volumes have appeared, commencing in 1784, and concluded in 1790; the Medical Society, whose memoirs are still continued, and have extended to six volumes; and another society, whose collected labours are entitled *Transactions for the Improvement of Medical and Chirurgical Knowledge*, in two volumes, appeared in 1793 and 1800. A collection also, entitled *Medical Facts*, has been continued in numerous volumes; and medical journals in a profusion which baffles our enumeration.

The conclusion of the 17th century was distinguished by some of the brightest luminaries which have illustrated this science; *Sydenham*, *Morton*, *Baglivi*, and *Boerhaave*, though the fame of the latter was chiefly conspicuous in the next century. Of *Sydenham* and *Morton* we need not speak, for their merits are sufficiently known; and the Boerhaavian system we have explained in a separate article. In treating, however, of this venerable and highly respected eclectic, we have mentioned a philosophical sect, whose tenets we have not explained. In fact, the sect fell so nearly within each century, that it was not easy to fix accurately its precise era. The application of mathematics to astronomy by Kepler, and to the laws of motion, as well as to the system of the world, by Newton, led to the opinion that its powers were irresistible, that it might unfold every secret of nature. *Borelli*, at the end of the 17th century, applied this science where it properly admitted of application to the motions of animals, and showed the advantages and disadvantages derived in these motions from the origin and insertion of the muscles. His scholar, *Bellini*, in the beginning of the following century, went farther, and, from mathematical data, endeavoured to explain many functions of the human body. *Keil*, a philosopher and a mathematician, rather than a physiologist, calculated from imaginary data the power of each organ, and gave the stomach, for instance, a force of compression which must so overcome the resistance as to destroy its organization; and *Pitcairn*, with his followers, calculated the ratio of medicines in proportion to that of the constitution. In the principles of medicine of this last author, and in some of the early volumes of the *Edinburgh Medical Essays*, this phrensy is carried to a most ridiculous height, indeed so far as to undermine its own best security; for, if such were truths, mathematics had no certain foundation. From the chemists and the mathe-

maticians, as we have seen, Boerhaave drew his theory; but his practice was founded on the sound observations of the Coan sage, and his most respected followers. The fatal doctrine of concoction held its ground, and was supported in all its rigour. Thus fever was not to be checked, but encouraged: most destructive delusion! millions have been the victims to this fancy.

While Boerhaave held the reins of empire, and ruled with a sway almost as absolute as that of Galen, two rivals arose who overturned his apparently well established dominion. Hoffman and Stahl were rival professors at Halle, yet without acrimony, and without, at least, open opposition. Hoffman was a voluminous writer, but not the founder of a sect; for he does not always reason with consistency, nor are his arguments directed to any definite system. He wanders from the mechanical to the chemical doctrines; but, in the midst of these, directs the reader's attention to the exertions of the vital powers, in changing the direction and the balance of the circulation. Stahl, with scarcely less industry, but with acuteness and talents eminently superior, aimed at changing the whole of the science. He acknowledged, with Van Helmont, a ruling power, guarding the constitution against disease, and repairing every defect which might occur; but, with this superintendance, he considered the human system as a living and an irritable machine, susceptible of various and irregular motions, and consequently of topical congestions. This is the meaning of "spasm," of "tonic motion," and similar expressions; nor can we avoid the suspicion, that, when Hoffman speaks of spasm, he means what Stahl styles his tonic motion, for each is attended with topical congestions. Whatever becomes of this idea, it is evident that the germ of this new doctrine gradually expanded. Even Boerhaave, in his later years, did not reject the consideration of a nervous fluid, though consistently with his humoral pathology he considered it as "inactive;" and Gaubius his successor treats at some length of the diseases of the vital solid. Indeed the heresy began in his own family; for his nephew, *Kauw*, Boerhaave, who practised with credit at Petersburg, considered the influence of the nervous system in his work entitled *Impetum faciens Hippocrati dictum*. Haller, though chiefly of the mechanical sect, and who is entitled to our gratitude for his industry, rather than his genius, assisted this new revolution by his experiments on irritability; and Dr Cullen at last constructed, on this ground, a system highly ingenious, though, like many first efforts, sometimes too refined, perhaps occasionally incorrect. See BOERHAAVIAN and CULLENIAN SYSTEMS. On the same foundation Dr. Brown has still farther refined; but, while the Boerhaavians made the human body wholly material, he considers it as wholly spiritual, created only by heat, motion, and other stimuli. See BRUNONIAN SYSTEM.

Of living physicians, as of surgeons, it is not "our hint to speak;" nor, indeed, in the present era, have we any revolution to describe, or any marked improvement to praise. When, in the history of surgery (see CHIRURGIA), we pointed out the objects of the surgeon, we discriminated those of the physician. We there engaged also in a slight disquisition on the talents and acquisitions necessary to the surgeon. This calls on us for a similar explanation; yet, as coming "nearer to our own business and bosoms," it is a task we would

wish to decline. Necessity, however, imperiously demands it; and the consciousness of holding the mirror up to what appears to us the character of an accomplished physician, will be our best shield against the censure we must consequently encounter.

It would appear superfluous to say, that a physician should be at least acquainted with the ancient languages, did we not daily see pretenders to that character without even a knowledge of their own. The observations of Hippocrates and his followers should be read in their own language; and we would engage to promise a classical scholar the highest literary entertainment from the simple elegance of the Coan sage, the polished eloquence of Galen, and the expressive terseness of Aretæus. Among the Latins his prospects are less alluring; and the Augustan elegance of Celsus must atone for the barbarisms of Cœlius. Yet in more modern times Lommius, Read, Friend, Heberden, and Baker, will compensate for Stahl and Brown; and the sterling sense of Haller, Gaubius, and Burserius, will instruct, if their language should for a moment disgust. The modern languages are equally necessary, at least the French and the German. It is indeed to be regretted, that vernacular tongues are so much employed; for no position is more truly unfounded than that what deserves to be translated has already appeared in an English dress. The Italian is perhaps less necessary; yet Sarccone, we believe, still retains his original garb, and different modern writers of that country seem to merit more attention than they appear to have received.

If, as has been supposed, the practice of medicine requires the active exertion of the intellectual powers with their full energy, it will at once be obvious, that every method by which the physician's views are early contracted must be injurious. For this reason, to spend the first period of his life in an apothecary's shop has appeared a plan of the worst tendency, for this is the time in which he must endeavour to attain an intimate acquaintance with the classics, a competent knowledge of mathematics and of natural philosophy. Man, the most glorious work of the Creator within our limited observation, is not indeed regulated by the laws of matter and motion; but each must be often taken into our views, in reflecting on the deviations from health and the means of restoring it; and, so intimately is every part of nature's works connected, that we cannot draw the line where the vital powers begin, and those of matter and motion end. Mathematics are highly necessary to enable the student to follow the mechanical philosopher, and to understand the mechanical physician; for it is highly disgraceful in the modern physician not to be acquainted with the principles of every sect, or unable to comprehend their mode of reasoning. Without mathematics, Haller, Hamberger, Bellini, Van Swieten, and Sauvages, will be often unintelligible. The utility of mathematics is not confined, however, to their aids in pursuing other objects. They accustom the mind to close, abstract investigations; give a habit of connected and accurate reasoning, of connecting consequences with premises by their strict relations, rather than by loose analogy. In these views we have often reason to regret the neglect into which the mathematics have lately fallen.

Natural philosophy is highly necessary, independent of its connection with matter and motion. We are

advancing rapidly into these branches, where, as in the human body, we see effects without being able to comprehend causes; we mean in the sciences of electricity and galvanism, and have reason to suppose that the discoveries in these will, at no great distance, materially illustrate the functions of the human system. It is disgraceful not to be intimately acquainted with each, and in the acquisition of either mathematics are useful, if not necessary. The great supports of this position are the papers of Columb and Van Swinden. Another assistant in acquiring this habit of close reasoning is logic, a science essentially useful, though, in consequence of its abuse, too much neglected. When properly regulated, it gives the distinctions so necessary to the clear enunciation of a proposition, and the conduct of the reasoning either in support or in opposition; and it leads the mind, by easy steps, to detect the fallacy of a too unlimited statement, of an unsuspected subterfuge, or of inconsequential reasoning. Were logic more generally studied, many bulky volumes would neither have tired our patience, nor disgusted our judgment. Fatal as its neglect has been in every science, it has not been more severely felt than in medicine.

Of chemistry we need not now speak: it is acknowledged to be an essential part of the physician's education; nor should any science which is supposed ornamental in a gentleman be omitted. Geography, for instance, may appear far from a necessary branch of medical knowledge; but it would be disgraceful to speak of the ipecacuanha as a production of Russia, or the cortex peruvianus of the arctic circle. A knowledge of botany is highly necessary, especially an intimate acquaintance with the natural families, as it will often enable a physician to apply his indigenous species of plants to useful purposes where the exotic is wanting.

All these are, or should be, preparatory sciences, for medicine itself is a study which will fill all the time usually allowed for its attainment. Where then can this varied knowledge be acquired? not behind the counter; not in dispensing the prescriptions of others; not in staring at diseases, without information, or without principles. In this way, the student either attains no knowledge or crude imperfect ideas, which he can scarcely ever correct; or, if correction is in his power, it will require more trouble than the acquisition of juster notions. This kind of education also narrows the mind in another view. We look with some partiality to our earliest instructor; our first ideas stick to us with peculiar force, so that it is of consequence where they are acquired. Those who are accustomed only to a narrow circle cannot easily expand their ideas beyond it, as the native of Switzerland thinks his valley scarcely less than the whole world. We do not indeed contend, that able and enlightened physicians have not, at times, escaped from the shop; or, on the other hand, that the deepest and most profound philosophers have been the best practitioners. Exceptions *prove* a general rule; but some distinctions are requisite in the full discussion of this question, which we shall soon consider.

We have, in different parts of this work, hinted that a physician should be, from his earliest years, educated with the view to his future profession. If the best parts of his life have been directed to other pursuits, he will seldom acquire that extent of information, and readiness of application, which the practice of his profession

requires. In the most advanced period of his life, what he may have seen at his first entrance into the study may happen to be applicable, though, through the whole interval, it has been never necessary. It must not be supposed, that the most splendid abilities or the deepest knowledge are *always* requisite. Many diseases are obvious in their causes, appearances, and treatment; but, on the other side, many serious complaints assume, at first, a common form, and it requires no little sagacity to trace them in their bud; no little knowledge to obviate the fatal consequences. Were it always possible to say whether a disease was common, great abilities or extensive knowledge might not be necessary; and we thus find physicians, with little real skill, but with policy and address, pass through life with credit, sometimes with the highest applause. It is not, however, enough to possess knowledge, but the mind should be ready and active in its application. It is often necessary to adopt at once a plan, and to pursue it with active decision: it is necessary to weigh contending difficulties, and at once to seize the path where the fewest or the least important appear, or where the inconveniences are counterbalanced by the advantages. This rapidity of decision, the result of great and extensive knowledge, as well as readiness of resource, is often equally the offspring of ignorance. No difficulty can be experienced by those who are unable to anticipate danger; and doubt, the consequence of different plans contending for superior eligibility, can scarcely be felt by those who have none. Physicians are called on, in general, to act with this prompt decision; and to hesitate is usually accounted a mark of ignorance. A man must have merited the confidence of the world before he can require time for consideration, and his reputation be firmly established before he can own himself at a loss.

Readiness of resource is partly owing to habit and long experience; but it may be easily acquired by a ready arrangement of ideas, and clear distinct views. The able and experienced physician, who can at once comprehend the object to be attained, will, at the same moment, perceive the various methods by which it may be effected, and he has only to choose the most convenient and the best adapted to the habit or idiosyncrasy of his patient. In his progress new views will generally open, and the soundest judgment is shown in steering between the opposite extremes of varying the plan according to the variety of symptoms, or obstinately persisting in it, notwithstanding every change of appearance. The first is pleasing to common observers, as it shows diligent attention; but it is a proof of weakness and indecision. The last, perhaps the most venial error, is the effect of too great confidence; and, unless accompanied with extensive knowledge which dictated the first opinion, and an acute sagacity in discerning the effects of the medicines, is scarcely less injurious.

It has been supposed, that extensive reading rather impedes by overloading the mind, than assists by giving information. Reading, however, with judgment and discrimination will produce no such effect. The mind should be so regulated that each new fact may be combined with the former stock, or, if, in opposition, reserved for subsequent mature reflection. It will then come in aid, to limit, to confirm, or to invalidate preconceived opinions. If reading and practice proceed, *pari passu*, the advantages will be still more considerable.

Each new observation may be soon brought to its proper test, and its value consequently justly appreciated. Facts in medicine have lately accumulated so rapidly, that we are oppressed by the load rather than informed by the substance. To discriminate between the true and the false, the important and the trifling ones, is no easy task. To say that any author states as a fact what he does not know to be true must appear harsh, perhaps unjustifiable; but the internal evidence often shows, that the case cannot have existed as the *writer* (we should have said the *author*) describes. When we find the symptoms loosely detailed, the necessary connections omitted, the effects of medicines imperfectly or inconsistently described, we may rest assured that it is the manufacture of the closet. When we find violent complaints cured by the most inert remedies, we may be equally certain that the violence of the symptoms are magnified, or the real effects of the medicines disguised; and, as has been often hinted, when an inventor describes his plan as infallible, suspicion should open all her eyes to detect the fallacy; yet many such deceptions occur with no culpable intention. A young sanguine practitioner seems to think every case the same, and always finds wonderful benefit from his plans. When he reviews them with a calmer, more experienced eye, he doubts whether they have been so successful as he supposed, or indeed whether they have succeeded at all. This is not indeed a singular case: it is the unavoidable progress of the mind from youth to age, from confidence to doubt, from hesitation to scepticism.

The mind of the physician should, in the most arduous and difficult circumstances, be unruffled. Doubt and hesitation should never be seen in his countenance, or in unsteady, vacillating councils. In the midst of uncertainty he should be calm. In the most adverse events, while he may express his surprise, he should never appear without his resources, nor until the case be wholly desperate should he suffer those around him to despair. For doubt and apprehension of the event there may be a more early foundation, and suspicions may be cautiously suggested that, should any given remedy fail, the danger would be increased.

In emergencies, friendly and affectionate anxiety may suggest additional advice, or a remedy of a doubtful quality and uncertain effects, the boasted panacea of some fashionable quack, recommended by an archbishop, a judge, or any other old woman; for, in such circumstances, each appellation is synonymous. No physician, whatever may be his character, is justified in refusing professional assistance, when required; nor, to his coadjutor, in this respect, ought he to withhold whatever his former experience with the patient has taught him. If he gains from his assistant, the patient has the advantage; it is his fault if the patient suffers. In every consultation it should be known whether the first or the second has the implicit confidence of the patient and his friends; and the conduct should be suitable.

In the administration of a quack remedy more caution is necessary. It should be known whether it is a mere name without effect, or whether it has any decided positive power. If the former, it may be indulged; nor is it a great sacrifice, in case of a fortunate event, that the medicine has the credit, if, in contrary circum-

stances, the friends of the patient feel satisfied that every thing which art could devise has been attempted. This doctrine we know will not be popular among physicians; but they ought to recollect, that to cure their patient is their first object; to gain fame, a secondary one. If indulged with their favourite remedy, they will agree to combine other means; confidence will be supported, hopes raised, the spirits cheered; and, in case of a sinister event, the candour and liberality of the practitioner will secure general esteem. Yet he would merit the severest censure, if, indulging such fancies and prejudices, he omitted, for a moment, the efforts which he yet retained. The conduct we recommend is only justifiable where the case is desperate, or the boasted panacea inert.

In some circumstances, however, the remedy is active, and the ingredients well known. The physician must then decide whether it is adapted to the complaint, or whether its effects may not be too powerful. When he has stated, fully and impartially, his opinion, the friends or the patient must determine. We think, that he is not justified in leaving, as has happened, the patient to his fate. It is rather his duty to look on, to watch, to regulate, or correct any errors. He may yet save the devoted victim from destruction, from falling a sacrifice to prejudices either his own or his mistaken friends.

There is yet another situation in which an active quack medicine may be allowed. In continued chronic complaints the patient is often weary of his physician, and willing to try the recommendation of some interested adviser. He has, for instance, been using a mercurial alterative, and wishes to try Spilbury's drops. They are no other. Why then may he not be indulged? Low indeed must be the credit of his physician, if he should suffer by adding one to the many boasted cures performed by this medicine, which is only the hydrargyrus muriatus in small doses, a preparation of mercury generally employed. Yet we must repeat, that, in every such instance, the physician is inexcusable if he do not guard the patient against any probable inconvenience that may result from the supposed qualities of the secret remedy, and suggest the best methods of preventing them. These few remarks we have suggested as a kind of supplement to the very liberal and judicious observations of Dr. Gregory in his most valuable lectures on the "Duties and Qualifications of a Physician," and to this work we would refer the young practitioner for his more general conduct.

Had we room, we might enlarge a little on the *policy of medicine*. Hoffman has left us a dissertation entitled *Medicus Politicus*, though its object is different; but the art in this age is greatly improved, and an amusing treatise, copied from life, might be easily written. Our object is however to make the practice of medicine respectable, not contemptible.

It was a question suggested respecting surgery, whether it had been improved in later periods. The same question has been agitated respecting medicine, and perhaps it may, in this part of our article, merit a short notice. The argument, that medicine has not improved, has been supported by the most inconclusive reasoning; viz. that we still resort to the older authors, and that diseases are still mortal as before. To engage

in an extensive discussion is inadmissible, but, as in the article referred to, we may adduce a few instances.

In the conduct of fevers, is it no improvement that the rigorous abstinence of the early days, enjoined by the ancient physicians, is, at least, abridged or softened? that the great heat, the close rooms, the warm stimulating medicines, and the sudorific regimen of the modern Galenists, are wholly abolished? It may be asked, whether either plan is justly or advantageously superseded; and we hazard little in replying, that the recoveries under the later mode of treatment exceed those under the former three times told. Death, from a fever, is now comparatively rare: formerly, recovery was equally so; and many, whom we remember among the recoveries, lingered out the remaining period of life without the slightest enjoyment of an hour's perfect health.

In internal inflammations the constitution is equally preserved by the rejection of the indiscriminate bleedings so often and so copiously employed; nor is the excitability exhausted by the numerous blisters applied, under the mistaken idea of derivation. In childbed how is the strength preserved, and inconveniences avoided, by the cool regimen, by the discharges from the bowels, and the early application of the child to the breast? How is the strength and health of the child augmented by copious and frequent ablutions? In dysenteries, what pains are saved by the free use of cooling laxatives; in scirrhus livers, how long is the life comfortably preserved by the free use of mercury? The paper would fail before we could enumerate the advantages of modern improvements in the practice of medicine. Let us take up the subject more generally. Abstruse disquisitions respecting the causes of disease, and the operation of remedies, are now seldom indulged. Our indications are more clearly pointed, and the means usually better chosen and more direct; less depending on pathological enquiries, and more closely connected with the changes to be produced. Dr. Friend was supposed to be master of all the medical science of every æra; and yet, if any modern physician, who had for some years escaped from his early studies, were to read his *Reflections on the Practice of the Ancients*, they would suppose themselves engaging in a new and most intricate science; so disguised and involved are the most common observations and directions. This was, in fact, our own case:

We had intended to have closed this article with a sketch of a medical library, but we feared to terrify the indolent practitioner, or to repress the timid. Yet perhaps we may find an occasion to resume this subject under a later article, *STUDIUM MEDICINÆ*. At the conclusion however of so long a work reasons of necessity must at last decide.

Le Clerc *Histoire de la Médecine*; Friend's *History of Physic*; Blumenbach's *Historia Medicinæ Literaria*; Schultze *Historia Medicinæ*; Conringii *Introductio*; Halleri *Bibliotheca Medicina Practica*.

See *CHIRURGIA*; *BOTANY*; *MATERIA MEDICA*; *OBSTETRICATIO*; *MEDICINA FORENSIS* et *POLITICA*.

MEDICINA FORENSIS et *POLITICA*. Medicine has for ages been the guide of the police and of justice, without ostensibly mingling in their contests. When Acron of Agrigentum is said to have kindled fires to

promote the circulation of air in order to check the plague, of Athens, or Numa constructed sewers to keep the imperial city from the noisome stench of impurities; they acted as able politicians and judicious philosophers; and an early work of Hippocrates on a kindred subject should have particularly fixed the attention of physicians. Many similar regulations are indeed the result of good sense, reduced to practice by an active mind and well directed views; but many years elapsed before regulations of this kind were digested by a regular scientific publication, professedly on the subject. The *Criminal Constitution of Carolina* was the earliest work in which the rudiments of forensic medicine were developed, and the first edition of this work appeared in the beginning of the 16th century. The origin of political medicine in modern times may be dated about forty years later, and its first publication by Joach. Struppe, at Frankfort, appeared in 1573. His work in quarto contains the necessary precepts for preventing the air from contamination by filth, by injurious occupations, and by sepulture in the midst of cities. He adds regulations respecting the occupations of millers, bakers, butchers, &c., on the proper instructions necessary for midwives, on the establishment of infirmaries, on the propriety of visiting the shops of apothecaries, and of guarding against the arts of quacks. In the same year, he published his *Anchor of the Hunger, Thirst, and the Health of Mankind*; in which he particularly treats of the substances which may occasionally supply bread, and the means of preserving meat from putrefaction. At the end of the same century, Fortunatus Fidelis of Sicily published his work on the department of forensic medicine, *De Relationibus Medicorum*; and, under the name of Reinesius, his *Schola Ictorum Medica*. The subject was still further pursued by Paul Zacchias, principal physician to the pope, who published his *Quæstiones Medico-Legales* in 1621, &c. in nine volumes, quarto, at Rome. About the end of the same century Paul Amman, a native of Breslaw, and a professor at Leipsic, published the *Medicina Critica seu Decisora*, as well as the *Irenicum Numæ Pompilii cum Hippocrate*; and, in the same century, G. Welsck of Leipsic published his *Rationale Vulnerum Lethalium Judicum*. We may just add, as objects of curiosity, that this author first described the purple miliary fever of childbed women, as a new disease, in 1655; and, about the same time, a German clergyman first described the method of recovering persons apparently drowned.

To pursue the history through the 18th century would be useless, and almost impracticable. We engaged in it chiefly from curiosity, and need only add, that the minor works on this subject are collected by J. C. Traugott Schlegel, published in six small volumes at Longosalissa; but we must remark, that of this city and some others we have found it impossible to discover the vernacular name. The obscure towns in Germany have not found a place in any Latin or geographical dictionary to which we have access.

To account for the numerous German and French publications on this subject, we must observe that the laws of these countries are much more minute in their distinctions respecting crimes than the criminal code of this kingdom. This may be one reason why the sub-

ject has been so much neglected, that it has not formed any portion of a course of lectures; and very lately only has a professor of forensic medicine been established in a British university. To treat of this branch of medicine, therefore, with all the subtlety of a German lawyer, will be unnecessary, and we must confine ourselves to the outline of those topics, which must be the subject of inquiry in an English court of justice.

We must first consider forensic medicine as it is a branch of medical investigation, and next as it is connected with the conduct of the surgeon.

MANIA is one of the most frequent subjects of forensic inquiry, in which the physician is called on to decide; and, to the disgrace of science, we find the most opposite opinions adduced by practitioners of eminence. Much depends on the period during which the physician sees the supposed lunatic, and more on a few necessary distinctions, which we fear are sometimes designedly neglected. It is possible for an interested relation to fix on a day when the patient is calm and rational, an hour when he is usually collected, to introduce the physician who pronounces him sane. Another, in different circumstances, might pronounce him mad. It is necessary, therefore, to guard against such deceptions, to visit him frequently at different times, and at the most unsuspected hours. If this is refused, a collusion will be evident. We remember seeing a man, who was confined for a crime and defended on the plea of idiotic insanity. We visited him frequently, while unsuspecting any such examination, and found the plea strictly true. Yet, when called into court for the purpose of acquittal, when cleaned and dressed, roused also perhaps by the novel appearance of the scene, his look assumed a meaning, and he was almost rational.

In the general relations of life, a man may be thoughtless, ridiculous, and extravagant, yet these errors will not be sufficient to fix the charge of insanity, which consists either in false perceptions or erroneous reasoning, on objects distinguished in their true colours. Many individuals of this kind require guardians for their property as much as persons really insane; but the law entrusts no practitioner with such discretionary power. The difficulty arises when this wild absurd conduct is attended with no such inconsistencies as lead to the suspicion, that the perceptions or the reason are affected. This situation is a question of prudence, rather than of jurisprudence, or medicine. The reflecting physician will not fix, unnecessarily, the stigma of insanity on a whole race; nor will he expose a family to ruin by a too great delicacy. In this difficulty, he will rather take the opportunity of a calmer moment to induce the patient to adopt such plans as may prevent the ruin of the family, and may properly make use of the alternative as an argument, in case of refusal. But this, as we have said, is not a medical question.

There is another doubtful state, in which the physician is often called on to decide, viz. when from disease, from general weakness, or any constitutional cause, the mind is so much enfeebled as to render it uncertain whether the patient can judge of the proper disposition of his affairs. This too is a question of discretion, for the afflicted person may be taught to answer common questions readily, or may be awed by some interested attendant. In this case, if the physician,

when alone with his patient, talks to him of his affairs, suggests, for the sake of a reply only, some objections to his arrangements, he will soon find whether the testator has judged properly, or only repeats a lesson. The circumstances themselves often suggest doubts; and when an infirm old man disinherits obedient or near relations, for the sake of those connected with him only by accident, the presumption is, that his mind is not sound.

We have said, in the article *MANIA*, that by a fiction of the law every mania, we have been informed, is supposed to be relieved by occasional lucid intervals, and that if the act of a madman is reasonable and proper, it is a proof that the interval was a lucid one. Thus in the case, which has just been considered, whatever be the apparent state of the patient's mind, if his will be judicious and proper, there is no reason why the physician should not pronounce him in a sound state. Yet, in criminal cases, the law is not equally indulgent, nor has it always, perhaps, been equally humane. Lucid intervals, in cases of murder, are not allowed, and the man who has been proved to be mad on the Monday and Wednesday is not allowed to be sane on the intervening day; yet decisions have occurred of a different kind; and an art in planning, a coolness in executing, a deliberation in the conduct, have been supposed to constitute soundness of mind. On these grounds lord Ferrers and Mr. Oliver were executed. Yet, if the *motive* is at any time connected with the hallucination, the subsequent action should certainly be considered as a part. In later trials the opinions have leant more on the side of humanity.

The question of confirmed insanity must be decided by a comparison of the patient's state with the pathognomonic symptoms. Yet there are many sources of doubt, and often room for hesitation. In many instances the mind wanders, at first, on one subject only; and, when the madman has any point to gain, he will, with great success, counterfeit a calm reasonable state. Each point must be carefully guarded; yet the experienced physician will not be easily baffled. A wildness of the eye, a tension of the skin of the temples, a dry furred tongue, often a hurried pulse, will explain the real state. The madman is also a coward, and we have drawn from this a good pathognomonic symptom. If threatened with some vehemence with any punishment, however wild and impracticable, he will shrink and tremble, forgetting all his art, or returning to his original deviation of mind.

Returning sanity is another point of doubtful distinction; nor do we see that it is possible to lay down any rules, except the absence of the pathognomonic of the disease. Yet we have often witnessed the return of persons from the appropriate receptacles, with a wildness of the eyes, a quickness of utterance, rapid unsteady motions, which showed corporeal disease, though the mind was calm. Such persons should not be pronounced secure; and, though confinement may not be necessary, the most pointed caution should be continued.

Dissembled insanity might more properly belong to another head, *morbi simulati*; but we may more easily speak of it in this place. An experienced practitioner will soon detect the absurdities which assume the form of insanity; for, though incoherencies, wildness, and

obscenity, may be imitated, the hurried look, the rapid pulse, the dry tongue, and the sleepless nights, cannot be assumed. Above all, the cowardice, the apprehension of punishment, the influence of threats, are seldom to be discovered. A French author details the symptoms of madness, for the purpose of this distinction, so elegantly as to induce us to copy the picture.

"Thus to neglect what most deserves attention, and to value what is least deserving of it; to rejoice or weep without an adequate reason; to despise what is terrible, and to fear what is ridiculous; to admire trifles, and to reject what is excellent; to love the objects of hate, and to hate those of love; to hope without an object, and to despair while in security; to be pleased with things which excite no agreeable sensations in others, and to fly from what every one would anxiously seek; to be timid with those who demand no deference, and bold to those whom they ought to respect; such are the infallible marks of a wandering mind."

In either of these cases, an excellent criterion may be found by inducing the supposed lunatic or the pretended convalescent to write. If engaged in a correspondence particularly respecting his own affairs, he will soon betray insanity, should it remain. In the servile war, the slaves who opposed the spears of their former masters yielded, when they saw them armed with whips; so the most furious maniac will often submit on presenting him a pair of hand cuffs, which will only irritate the counterfeit.

MORBI SIMULATI. Dissembled diseases sometimes claim attention in a court of justice, but perhaps more frequently in an infirmary. The latter is, as usual, the school. Insanity, of which we have already treated, is the most frequent, and, next to it, are the different nervous and spasmodic complaints. We must not, however, always accuse the patient. The timid girl will have the catchings and the gesticulations of chorea more frequent on the access of a stranger; and the disease, to the attendants apparently cured, will appear to return. On the contrary, these and some other diseases will occasionally seem to lessen on the approach of the physician. The wanderings of delirium will cease, and the wildness of the eye be converted to an expression of meaning. These are circumstances which must be kept in view, as tending to explain the opposite course. The diseases counterfeited are catalepsy (commonly styled ecstasy) and convulsions. Some patients possess even a command of the features, and others, it is said, of the pulse; but, in general, an unchanged expression of countenance and an unaltered pulse will explain the deceit. Boerhaave is reported to have cured real fits by threatening, *câ quâ pollebat gravitate*, to burn the next patient seized, with a hot iron. To heat a poker with the same gravity has cured pretended ones, especially if they felt the heat approaching. Plunging the suspected patient in cold water is still more effectual, and it will not injure if the disease be real. Dashing cold water in the face, unsuspectedly, will succeed; but, as the bathing requires preparation, it will not be necessary, in case of deception, to proceed to extremities.

Pains in the limbs, which sometimes happen without fever, is a fertile source of deception, and blisters will often have little effect in detecting the fallacy. We have not, however, found patients of sufficient constancy to endure a few smart electrical shocks; and the

galvanic, if the skin is punctured, will be probably still more effectual. In cases where fever must necessarily attend, the detection is easy. No one can counterfeit the febrile symptoms enumerated under FEBRIS; though by topical stimulants inflammation and fever may be brought on.

In the time of Galen, tumours were produced in the knee by the *scimen thapsi*; and Zacchæus, in his numerous quartos, has copied many tales of this kind. We have seen abscesses produced by inserting splinters under the skin, continued ulcers by stimulating dressings, and even hæmoptoe occasionally returning by artificially exciting cough. Yet while we awaken suspicion, we would not silence the feelings of humanity. We have seen cases where no deception could exist, where no motive could be found for fallacy, that appeared at the first sight fictitious. We have known the urine retained six weeks without any remarkable vicarious discharge: we have known a nail of no inconsiderable size, such an one as fastens the hoops of small barrels, retained in the throat till it formed an abscess: yet in each case no deception could exist.

The mendicant with his ulcers counterfeits both deafness and dumbness; but these deceptions are best detected by the beadle, or by a little address. "How long have you been dumb, my good friend?" says a passenger, with the most insidious humanity.—"Three weeks, sir," replied the incautious deceiver.

IMPOTENTIA. This disease rarely requires the interposition of a physician in a court of justice. The complainants, who are commonly females, can relate their grievances in terms sufficiently guarded and clear. The causes and cure we have already considered, and we see but one circumstance in which it requires our attention in this place. The extirpation of the testicles is an operation obviously designed to prevent generation. But in the human species, as we have seen, they are originally seated in the abdomen, and fall through the rings of the muscles into the scrotum. If they do not appear in the scrotum it is no evidence of their absence, and it has been said that their influence on the genital powers are more conspicuous while they remain in their original seat. It is at least certain that this influence is not less, so fallacious is the logical maxim, when applied to medicine, *De non apparentibus et non existentibus eadem est ratio*. If they did not exist, or were not evolved, the beard, the graver tone of voice, and every mark of virility would be absent. If they had been extirpated, the *cicatrix* would remain. It has been said that one, three, and even four, testes have been discovered. One has certainly been lost by accident, has decayed, or been extirpated, without injuring the generative power: sometimes the other has enlarged, but more often continued of the same size, with little apparent diminution of the powers. The stories of three and four testes we cannot disprove; but there is much reason to suppose that many of these have arisen from an enlargement of one or each epididymis. They at least furnish no grounds for a legal process.

From what has been said under the article IMPOTENTIA, q. v., the physician will be sufficiently directed in his judgment; nor need we enlarge with the disgusting indecency with which the old authors expatiate on this subject, nor on the public display of the active powers in the venereal act, which some of the canons

enjoined. The original authors seem plainly to hint that this indecency was only the prelude, like the modern actions for crim. con. to a divorce, and designed as a justification of the most licentious conduct; for divorces, they add, were less frequent since such exhibitions were abolished. This practice began, it is said, early in the thirteenth century, and ended about a hundred and fifty years afterwards.

Poisons. This frequent cause of violent and premature death is often the subject of inquiry in courts of judicature, and the physician is usually called on for his opinion. Science has been often disgraced by the crude, the injudicious, and often the opposite, opinions offered on these occasions; nor has humanity had less cause to regret the sacrifice of lives on the most vague and inconclusive evidence. Poisons may be accidental or designed. We shall begin with the latter.

The marks that poison has been administered are the sudden appearance of extraordinary and unsuspected symptoms, as uneasiness, nausea, an acute pain in the stomach, palpitations, faintings, disagreeable and fetid eructations, vomiting of blood, and bile, hiccough, sudden debility, smallness and inequality of the pulse, cold and clammy sweats, coldness of the extremities, paleness, livid nails, general œdematous swellings, windy distention of the abdomen, sudden relief with an equally rapid return of pains, blackness and swelling of the lips, burning thirst, loss of voice, a livid countenance, vertigo, convulsions, rolling and starting eyes, loss of sight, with a dilated pupil, lethargy, suppression of urine, a fetid smell of the whole body, purple eruptions, livid gangrenous spots, and an alienation of mind. All these symptoms are undoubtedly equivocal, and occasionally attend other diseases. They are marks of poison only when they come on suddenly, without any known cause; when the food, if unsuspected as the vehicle, sudden cold, violent affections of mind, or deleterious vapours, cannot be accused; for these will induce many of the symptoms, though seldom in so considerable a degree as arises from poison.

If the patient be not a suicide, and still retains his senses, he can explain the taste of the food, or medicine, which has induced these symptoms, so as to direct the future inquiries. When no satisfactory explanation can be obtained we must depend on the evidence collected on dissection. Poisons, so far as they are the object of our present inquiry, are violent, inflammatory, stimulants, or sedatives. The pungent stimulants betray themselves by the taste, the pain in swallowing, and the inflammation of the fauces; and they must be treated under the head of accidental poison, as they cannot be given without suspicion. The chief substance to be considered here is arsenic, which is nearly tasteless, and violent in its action, even in trifling doses. Its power is shown by violent inflammation and gangrene in the stomach; and it is discovered by calcining the contents of the stomach with the black flux, when the smell of garlic will betray even such an impregnation as will not often be fatal. Some of the saline mercurials show no very decided action on the tongue or fauces, and will produce similar effects. These may be discovered by adding ammonia, and heating the whole in a close vessel, when the mercury will be so far revived as to whiten copper on rubbing. In this way mercury can be often discovered in those quack medicines where its

existence is utterly denied; for the ammonia contributes to precipitate the mercury, reduced in part to its metallic state, and enables it to appear on the copper. The suspected substance, if arsenical, heated between plates of copper, will give a whitish tinge to the part of the plates in contact with it. Independent of these trials, when the stimulant poisons have been the cause of death, the abdomen is greatly inflated, becomes rapidly putrid, dark spots appear on the body, erosion, inflammation, and gangrene, are found in the fauces and stomach, the blood is black and collected in the veins; above all, the villous coat of the stomach is destroyed. One other discriminating appearance, on dissection, is mentioned by a respectable author on jurisprudence. If, after a body has been long buried, should gangrened spots be found in the stomach, surrounded by a reddish circle, these were effects of changes during life. Should the colour of the whole be uniform, the putrefaction took place after death.

There are other poisons which kill by a partial stimulus. The chief of these is cantharides; but their peculiar action on the bladder will point out the cause. The violent inflammation, the rapidity with which it hastens to gangrene, will at once betray the crime, and, at the same time, point out the culprit. No such can escape.

The colocynth, the elaterium, and the tithymali, betray themselves by their taste, as well as by their local action, and can neither escape the detection of the person himself who is the subject of the crime, nor the attendant physician.

The narcotic poisons like the others, produce vomiting; but the faintness which is the effect of the vomiting in the former cases is the apparent cause of it in the present. The rapidly sinking strength, the dilated pupil, convulsions, stupor, sleep, vertigo, swelling veins, and cold extremities, point out the cause. Fortunately there are few such substances that do not betray themselves by their taste; but there *are* such, though we shall not point them out; nor shall we mention any poison that *can* be secretly administered. It is incumbent, however, on the practitioner to be cautious in these instances respecting his decisions; for no chemical analysis will assist him, and his only guide will be the discharge of substances which the powers of the stomach cannot change. He must compare with anxious attention the appearance of the symptoms after the supposed cause; trace with diligent circumspection every *other* circumstance that might have produced the effect; examine with care the patient's usual habits, his predispositions, his complaints, and at last remember that every medical conclusion is doubtful. Should he then be positive when the life of a human creature is at stake? One trial has been falsely considered to be decisive, viz. the effects of what might remain of the supposed fatal beverage on animals. This will hold true of the stimulant poisons; but by no means of the narcotic. The most innocent substances of this kind are occasionally fatal to animals; the narcotics, most injurious to man, are to many animals innocuous; and the human fluids changed by putrefaction are themselves poisonous.

Accidental poisons are received in the food, or are hastily swallowed by mistake instead of a medicine, before the taste betrays their nature. The former are chiefly copper, arsenic, and lead; the latter, nitre, camphor, ammonia, or the mineral acids.

Copper is greatly dreaded, and has frequently been accused with little reason. Copper culinary vessels, bell metal mortars, and all the various means by which this metal can be introduced to the system, have received an indiscriminate sentence of banishment. Injuries have undoubtedly arisen from them, and we would earnestly join in deprecating their use. When, however, we have said this in the way of caution, we may be allowed to add, that the dangers have been greatly magnified. The taste of copper is so peculiar that it can scarcely be disguised, and it will not generally fail to give the alarm in doses far distant from dangerous ones. Hunger, or eagerness to taste a luxurious dish, may however, hastily impel us, and such vessels should be avoided. The effects are chiefly on the stomach, and the quantity taken must be considerable to endanger life.

Arsenic has been swallowed accidentally when joined with any sweet substance to poison flies, or with other substances to destroy rats. The effects are so marked and discriminating as not for a moment to mislead, and they have been sufficiently detailed. It has been supposed that this metal may be accidentally introduced into the system when employed in fining wine; but for this purpose it is now wholly disused in this kingdom.

Lead has been accused of producing the Poitou colic when united with cyder, either as this metal is presented to it in the instruments employed in pressing the apples, or as added to correct the acidity of either wine or cyder. We cannot deny that in each instance it has produced the effect, since it is the peculiar consequence of swallowing any saturnine preparation. But these are by no means the constant, or indeed the most frequent causes of the disease. Another source is said to be the glazing of the common earthen vessels, since lead is used in the process, and in such vessels pickles are usually kept. Lead is not, however, always the substance employed, or it is not dissolved by the acetic acid. We have kept vinegar in such vessels for many days in a warm place, without its discovering the presence of lead on the addition of the most delicate tests. The alarm, therefore, we think unfounded. In these circumstances caution is almost as necessary as in the former, where the life of an individual is at stake. The credit of a house, the character of a professional man, are involved; and the feelings of those whose want of caution may have occasioned the mistake may be so excessive as to endanger their lives. Though their negligence may merit punishment, yet that punishment may be too severe.

Ignorant druggists have sold camphor and nitre instead of neutral salts; and by mistaking the vials, the aqua ammoniæ, some mineral acid, or other stimulating substance, has been swallowed. The eagerness to escape from the taste of a disagreeable medicine hastens the act of deglutition, and the error is sometimes not discovered till the whole has been swallowed. The medical treatment is not our object in this place. The only connection this subject has with medical jurisprudence, is to ascertain the cause of death when such substances prove fatal. If taken as a medicine, the effects of the poison must be compared with the symptoms of the disease; and should the latter be highly dangerous, the feelings of the mistaken attendant may perhaps be

relieved by the humanity of the physician's declaration, in which, if he offers truth in her fairest and most favourable hue, he will do no injury to any individual.

The symptoms which distinguish camphor swallowed in large doses are, giddiness, vertigo, delirium, and convulsions. Nitre produces, with the common symptoms of narcotic poisons, bloody discharges from the bowels and the urinary organs. The mineral acids and ammonia do not greatly differ in their effects, which are those of violent stimuli, rapidly exhausting irritability. Inflammation in the mouth, or fauces, with a burning heat at the serobiculus cordis, are followed by vomiting, by the sense of a heavy load in the stomach, and a consequent diminution of all its powers. From these symptoms, the remains of the medicine, and the report of the patient's feelings when it was swallowed, if he is able to report them, the nature of the deleterious draught may be ascertained.

The case of the SUICIDE is deplorable; yet he often repents before the termination of the scene, and can lead us to form a judgment of the treatment necessary. The physician's testimony may be called for, and no rule of morality can, we think, be violated by softening the most offensive circumstances. The feelings of the relatives may be essentially hurt by marks of disgrace to the body, which we believe never once deterred a determined suicide.

APPARENT DEATH has been the subject of much discussion, and premature interment the object of universal apprehension. Numerous are the tales told on this subject, many of which are exaggerated, and the greater number probably false. It is, indeed, possible that a person not yet dead may be interred; but it is highly improbable that any one should, in such a situation, recover their senses and recollection; for before these returned they must be suffocated by the want of air. The complaints, in which such apparent dissolution is most common, are the spasmi and comata of Dr. Cullen, drunkenness, excessive evacuations, narcotic poisons, strangulation, drowning, breathing deleterious gases, excessive cold, sudden and violent terror, and violent passions.

The want of motion, or feeling, of respiration and pulsation in the arteries, are neither singly nor in conjunction signs of death. The motion of the carotids, in the greater number of instances, continues longest, and their state should be most carefully examined. The experiment proposed by M. Bruhier is, to draw down the lower jaw, and if it approaches spontaneously the upper jaw, he thinks it a conclusive sign of some life remaining; but this may happen from the elasticity of the ligaments and other causes. It is certainly an equivocal proof. The eyes furnish the most certain signs, independent of putrefaction. If their transparency is lost, the eyeball sunk and wrinkled, and the pupil dilated so as not to contract by the strongest light, resuscitation is no longer in our power. The sunk features, in the eyes of experience, are a proof almost equally satisfactory; but putrefaction furnishes the only unequivocal symptom. Yet this we cannot always wait for. If any legal question depends on the state of the internal parts, dissection must be attempted at an earlier stage, since putrefaction changes every appearance by which we are enabled to decide. In cases of the slightest doubt, it is recommended to commence the dissec-

tion in the parts less essential to life, that if the stimulus of the wound excite the action of the remaining powers no considerable injury may ensue.

VIOLENT DEATH is apparently ascertained without difficulty; and when the cause proceeds so far as to destroy the organization of a part essential to life, little hesitation can be felt. Hæmorrhages, and the appearance of contusions, are often fallacious. The former certainly take place from a variety of causes independent of violence, and the latter may arise from petechiæ, or similar causes. We can scarcely, however, conceive a question to come before a court of judicature, where the difficulty would arise whether death was occasioned by a putrid fever or by blows; and we think the decision of the father of forensic medicine, Zacchias, decisive in this respect. In case of violence, he observes, there is an extravasation under the skin: the lividness from other causes only discolours the surface by a change in the skin itself. We know that Stoll in two cases discovered a considerable extravasation under petechiæ; but these instances are rare, and the danger of mistake very trifling. On the other hand, considerable extravasations may take place internally, without the surface being affected, as where the bruise consisted of a large heavy weight, which gave a considerable shock without making an impression on any particular part. This cause of death may, however, be discovered by dissection; though, undoubtedly, bruises after death may, before the blood has coagulated, occasion similar appearances. This source of error must be carefully investigated in the particular cases.

One very important subject of inquiry arises, however, out of these discussions. If a man, in an accidental or premeditated struggle with another, by any extraordinary exertion, break a blood vessel and die, though the struggle occasioned the death, yet it is deemed accidental. If this struggle be a pugilistic contest, where personal animosity is unsuspected, and the person thrown dies on the spot, a doubt will arise how far his antagonist was the cause of his death. Again, if, in the violence and heat of a quarrel, a person strike another with an inconsiderable weapon, and death follows as much from the passion as the blow, the doubt will be increased. In each instance, the physician and surgeon are called on to decide; and we know no cases in which such contradictory evidence has been given. The principles on which the decision should rest appear to be these. When, from prior complaints, any weakness or predisposition to disease, hereditary or otherwise, can be discovered; when the violence is such that, in a sound healthy body, it would not probably produce any dangerous effect, the blow or the fall should not be accused. If a man, subject to a spitting of blood, in a struggle should break a blood vessel; if a person with a full florid complexion, and a short neck, whose parent had died of apoplexy, and perhaps about the same age, should fall down dead in a trifling contest, where the exertion was inconsiderable, we should certainly not convict his antagonist of any thing but imprudence and misfortune.

When any contest has taken place, independent of personal animosity, and some slight injury has been seemingly received, the subsequent conduct of the patient should have great influence on the judgment of the practitioner. If he has received injury in his side or head, and, instead of a cautious mode of diet, should

indulge in every irregularity, the pleurisy or phrenitis that might ensue should not, in justice, be attributed to the antagonist; nor, when the proper distinction is made, will the law, we believe, condemn him. This is not, however, the place to discuss a legal question, but to point out the foundation for the physician's opinion. The case is somewhat different when an abscess has followed external injury, independent of any irregularity of the patient's conduct. The physician must then decidedly attribute death to the *consequences* at least of the accident; and the legal distinctions will regulate the degree of criminality, and, of course, the punishment.

We have for some time been trenching on the province of the surgeon; but to introduce those parts of our subject which are more peculiarly his object, we must offer some remarks on the *DISSECTION OF BODIES*, with a view to discover the disease which has proved fatal, or the nature of the wound, in complicated cases, which has been destructive.

Dissections are opposed on many grounds. We shall notice only the objections which urge that by this means we discover effects rather than causes, and that complaints may have occurred either in the minuter parts, which cannot be detected, or in the nervous system, which are not cognizable by our senses. Undoubtedly we more often observe effects rather than causes; but the objection will only apply when the anatomist, from ignorance, cannot detect the difference; or, from haste, will not wait to examine. The source of great error has been the partial examination of the part apparently most affected. We remember the dissection of a person supposed to be starved. The stomach was empty and full of wind, but not contracted. Some doubt remained; for the mesentery had not been examined, in which the conglobate glands were afterwards discovered in an enlarged and scirrhus state. Many similar instances might be adduced; and we may here add, that, in general, every cavity of the body should be examined with care, particularly the head. Complaints also may undoubtedly occur in parts of the body which even an exact anatomist may not think of examining; but these, we believe, will seldom prove fatal: nor, except from deleterious gases, is there any probability that the nervous system will be so much affected as to produce death, without leaving evident corporeal traces.

In medical jurisprudence, however, dissection is absolutely necessary, as the law requires the best evidence that can be procured, and various cases may be stated in which it is essential. A man, for instance, is found dead in a close apartment, in which charcoal has been burning, or which is in part consumed. The cause will appear evident: but dissection may discover traces of poison or of blows; and the fire may have been lighted to prevent suspicion.

When the dissection is determined on for the discovery of the cause of death, it should be attempted early, before putrefaction can have changed the appearance of the parts, and with as little motion as possible, that the relative situation of the viscera be not disturbed. The whole body, particularly the head, sternum, and abdomen, should be cautiously examined by gentle pressure. All the natural openings should be carefully sounded, and each part opened in succession, beginning with

that which is most probably injured. The order of the examination is of more consequence than has been supposed. If, for instance, in the dissection of the body of a new born infant, to ascertain the cause of its death, the heart and lungs be first opened, the copious discharge of blood will drain the large vessels, which will be found empty, and a strong suspicion will consequently arise that the child died of an hæmorrhage, by neglecting the ligature on the funis. So, in examining a wound and its direction, every thing must be avoided which can disturb the relative situation of the parts; for to establish the cause of death it is necessary that the direction of the instrument should be accurately ascertained. In ruptures of internal vessels this caution is of less importance; yet, when there is any suspicion of the cause, it should be traced with as little disturbance of the relative situation of the parts as circumstances will permit.

The mode of examination is known to every surgeon; but it is highly necessary that he should be acquainted with the natural bulk and colour of the parts, and with the changes which fermentation, inflammation, and putrefaction will successively, at different periods, produce. The swelled abdomen and livid spots on the side may give suspicion of poison; but they are the effect of a separation of air, and the necessary changes in consequence of a warm season. If an inconsiderable wound, from its place or its direction, proves fatal only after some time, the previous inflammation will close it so that it shall appear too inconsiderable to be the cause of death.

RAPE. The ancient authors on forensic medicine are full on this subject, and unnecessarily minute and indecent. The examination and marks of violence will alone determine the judgment of the practitioner; and for this purpose the English law has wisely determined that the complaint should be immediately made, since the injury can then only be best ascertained. The existence of the membrane closing the entrance of the vagina, deified under the name of Hymen by the ancients, has occasioned some controversy. The moderns have wisely cut the knot, and admitted, that though it is a sign of virginity, yet its absence is no proof of violation, since it may be destroyed in a variety of ways without suspicion of impropriety. An observation of Buffon, which we believe to be correct, will explain some of the apparent contradictions on this subject. He observes that this membrane is seldom found in young children, or in girls long previous to puberty. It is at that early period folded in wrinkles, and expands, as the *custos horti*, only near the age of womanhood. It is certain that its existence has been denied by anatomists of eminence, who, in order to "make assurance double sure," in such a doubtful point, have sought it in girls from four to ten years of age. The marks of violence, and the evidence of the young woman, according to our laws, alone decide, and these require no further medical discrimination than we have stated. The swelling of the neck, which the "*hesternum monile*" can no longer surround, the blackness under the eye, the sullied whiteness of the cornea, must be referred to the list of old women's stories, which sounder science spurns at.

SUSPECTED PREGNANCY. On this subject a surgeon is often consulted, and we have already stated in different articles the foundation of the distinction. (See

CONCEPTIO, GENERATIO, and ASCITES.) We shall here, however, give a general connected view of the subject.

If a woman, who has been previously regular and in good health, at once complains of obstruction, without any well founded cause, as cold, fright, &c. suspicion must be kept alive, and active medicines avoided. The complaints which arise from pregnancy, though of a similar nature from those owing to suppression, yet greatly differ. In the first weeks the pregnant woman feels no inconvenience, and then only from sickness, and chiefly in the morning. In the intervals of sickness the spirits are free, and in the evening the appetite is also good; while, from obstruction, vomiting is an uncommon symptom, the languor comes on more slowly, and the symptoms are by no means worse in the morning. In the former case the complexion is clear, in the latter pale and dark: in the former the eyes often lively, in the latter uniformly dull. Not many weeks elapse before the breasts swell, and a pink or brown areola appears round the nipple. The former state of the breasts may not be known, and the areola in many women is naturally dark. Yet in a thin woman it will be at once seen, if the breasts are disproportionally full; and even in a more lusty one their firmness will betray an increased bulk, while in suppressed menses the breasts are much extenuated. The areola in a pregnant woman is also unusually extensive. After the fourth month the swelling arises above the pelvis in the form of a round, circumscribed ball, and the sickness usually goes off, while the spirits become peculiarly free and cheerful. At this period the state of the os tincæ may be discovered by the finger, and will at once preclude all hesitation. See PRÆSENTATIO.

We have not mentioned the sensation of motion in the uterus, because we proceed on the supposition of concealment. The same cause may prevent our knowing the state of the menstrual discharge: but the vomiting, the tumour of the breasts, the darker areola, cannot be concealed, and the tumour of the abdomen at the subsequent period will be decisive. At this time, also, and often more early, a slight pressure will produce a flow of serum or milk from the nipple. Hebenstreit indeed observes, that many women, not pregnant, can bring on a discharge of milk at will; but we have no reason to think that moderate pressure, independent of long continued irritation, or suction, can produce it in this climate.

Medical authors, kind to the fair sex, have been anxious to point out the fallacy of all these proofs; and we shall so far join with them in urging the practitioner not to hasten the decision. Certainty is at no great distance, and it is prudent not to endanger driving the woman to despair. This may occasion the worst of crimes; and, if though guilty, she escape, she may live to repent, and repair to society the injury which her former errors have occasioned.

It sometimes happens that women pretend to be with child, either to impose a fictitious offspring on a credulous companion, or to avoid punishment. The determination is in this case more easy; but should it be prudent to delay the decision, a most unremitted vigilance is necessary.

Suspected delivery very often claims the attention of the surgeon. The signs, however, though singly equi-

vocal, are, together, certain. The very considerable relaxation of the vagina, the laxity of the teguments of the abdomen, the want of the fourchette, the thin membrane which unites the labia below, the peculiar swelling of the breasts, the extended areola, milk peculiarly thin and serous, with the unequivocal smell of the lochia just going off, will decide. Exceptions may be made to all these as well as to the signs of pregnancy; but the experienced eye cannot be deceived.

Retarded or premature delivery. Nothing can be conceived more ridiculous than the discussions of medical juriconsults on this subject. The ancients contended that every animal had a fixed period of gestation except the human female; but this is by no means true: and the moderns have tortured their invention to explain why delivery should be retarded. We need not enlarge on the subject; for our laws speak plainly that if a woman lies in within eleven months after the death or the possibility of the access of the husband, the child shall still be his; and the axiom *pater est quem nuptiæ demonstrant*, be uncontroverted. It is not our business to oppose the law, but to explain it, though we may still remark that it is peculiarly complaisant or indulgent. On the other hand, the law, we believe, recognizes only a living child of seven months to be legitimate, if former access can be denied: a circumstance which can seldom happen.

ABORTION. This is a subject which, by our laws, can scarcely be considered as an object of medical jurisprudence; for no statute is in force to punish the means of procuring it. The civil law made many unscientific, and even ridiculous distinctions on this point, resting on the period when it was supposed the fœtus began to live. We have now reason to think that life commences from the moment of impregnation. There is, however, a nice distinction in the English laws, which can never be applied without the most rash, unwarrantable decision of the physician or surgeon. If, says Dr. Burn, whom we quote, by a medicine given the child is killed in the womb, "it is great misprision, but no murder;" "but if the child be born alive and dieth of the potion, or other cause, this is murder." The opinion, we say, is inapplicable: for where is the physician who will decide that a weakly child might not have been so without the potion? and the vague clause distinguished by italics must make the whole "words of sound signifying nothing." There is, however, another view which we must take of the subject. An author of the purest morality, the most extensive benevolence, and the soundest religion, Dr. Percival, has dropped a hint, that it may not be unlawful to procure abortion where the size of the pelvis is not adapted for the birth of a living child. This is a latitude which we cannot sanction. A more recent (*we believe* a more recent) proposal of a celebrated accoucheur, who suggests in such circumstances, the propriety and advantage of bringing on labour at the end of the seventh month, is greatly preferable. In this case, though the attempt is peculiarly difficult, and can only succeed in the most experienced hands, the health of the mother is less endangered, and the child may be preserved; nor, on the whole, does humanity, so strongly revolt at the attempt. Yet, as we have said, the whole should only be under the conduct of a man who unites resolution with discretion, and judgment with humanity.

INFANTICIDE. We know not when we have found greater difficulty in speaking on any subject than on the present. The weight of arguments seem often to bear hard on those who are the objects of the greatest compassion; on unhappy women, deluded to their ruin, struggling with remorse, with the apprehension of disgrace, acting from a momentary phrenzy in self defence, often inconsistently and improperly subjected to suspicion from circumstances wholly beyond their power, and to conviction from the fortuitous occurrence of events not within their calculation. On this subject particularly, and indeed in every branch of medical jurisprudence, we strongly advise the practitioner to be cautious. He may reason as a physiologist, but he should act as a man of feeling and reflection, who knows that no medical conclusion is certain, and that the life of a perhaps innocent individual may be sacrificed to his hasty oracular decision, perhaps to his inadvertency. The punishment of a crime, says Beccaria, cannot be strictly called just or necessary, while the law has not employed the best possible means of preventing it. The law is indeed silent; but modern refinement, the precision of outrageous virtue, which admits not of the penitence of a sinner, urges the unhappy culprit to the worst of crimes.

In such circumstances the woman, from the causes already stated, is alone, her mind agitated, her resolution weak, herself spiritless and indecisive. The labour is perhaps rapid, the child born during fainting or convulsions, and lost from want of that attention which no law enforces, and which the apprehension of disgrace prevents her calling for. A state of this kind may be ascertained by subsequent faintings, peculiar debility, a low fluttering pulse, paleness, and subsequent œdema. Should these symptoms not occur, let us not yet decide without hesitation; for other circumstances should be also considered.

The first question must be, was the life of the child so perfectly established as to be probably continued after its birth? This is answered by its appearance, and the perfect, the complete development of its organs. It may be again asked, was it not dead before delivery? According to Alberti, if dead previous to delivery; the limbs are flexible, the skin wrinkled or soft, the colour yellow or livid, the abdomen sunk, with marks of commencing putrefaction, particularly about the navel, and the umbilical cord empty, yellow, livid, and apparently dissolved. The appearance of the cord is, however, equivocal; for the access of the air will, in a short time, produce the same changes. Indeed, all these appearances are the result of putrefaction, and the child may have died only a very short time previous to its birth; nor are authorities wanting to show that, while the access of the external air is prevented, putrefaction does not soon take place. (Heister, Alberti, and Hebenstreit.) The marks of apparent violence on the body are by no means decisive; but we have already, when speaking of contusions, laid down the best diagnostics on this point.

If an infant has breathed, it is supposed to have lived; but how many weakly infants are born alive, without breathing for many minutes; and how often, on the other hand, after a hard labour, does the child breathe once or twice, and then die? That the child may breathe before the delivery is complete, and die before it is fully born, is a fancy within the verge of possibility only,

but too improbable to induce us to enlarge on it. A child, indeed, wholly perfect, may be strangled in its birth by the twisting of the umbilical cord round its neck; and it has been doubted whether, in this case, it is suffocated or dies apoplectic. It is probable that death is rather the consequence of the stoppage of the circulation through the cord itself; but this is of little moment as the mark remains. May not this mark, however, be the effect of violence? It certainly may be so; and the famous experiment of the lungs sinking in water is adduced to determine the doubt.

In a child that has not breathed, the lungs occupy the upper part of the chest, so as to leave the heart and pericardium exposed to view. But when the lungs are distended by respiration they fill the chest, and become specifically lighter than water. The English courts do not admit this experiment as evidence, and we are unwilling to disturb their decisions. We shall, therefore, add a few words on it as philosophers rather than as forensic physicians.

Heister observes, that the experiment is indecisive, because scirrhi in the lungs will make them specifically heavier than water; but who would be so weak as not to examine whether the experiment was tried on a morbid or a sound part; for the morbid lungs even of an adult will sink in water? He adds, that he has seen a child who had breathed twenty hours, whose lungs sunk in water; but he here speaks of the whole viscus, not of any particular portion, on which the experiment ought to be made. Again, it is contended that when putrefaction has taken place, the lungs of a child who has never breathed will swim. This fact is positively denied by at least equal authority; and, in reality, the lungs are scarcely susceptible of putrefaction, even when it has taken place in a considerable degree in the other parts of the body. If there were, however, any ambiguity, it may be at once removed by a slight attention. The air, separated by putrefaction, may be observed in the water passing along the divisions of the lobules, while air within them is invisible.

It is certainly possible that the mother, in attempting to revive a still born child, may endeavour to inflate the lungs by her own breath. Anatomists of eminence have differed on the possibility of success; and we own that it appears to us impracticable, since the force of the expiration must be sufficiently great to expand the thorax, and the nostrils must be at the same time closed. Humanity will, however, take this source of expanded lungs into consideration when the life of an individual is at stake.

The colour of the lungs, which is of a bright red previous to inspiration, their situation in the thorax, and the situation of the liver and stomach, as well as the shape of the diaphragm, will afford more decisive proofs (Sabatier *Memoirs de l'Academie Royale des Sciences*); but we will not accumulate what may be adduced to criminate.

Suppose it, however, ascertained that an infant is born alive, does it follow that the mother has been its murderer? The English law allows the concealment of pregnancy, and the want of provision for the infant, to be presumptive proofs of her guilt; though this has been most wisely and humanely put out of view by constituting it a distinct crime, with its appropriate punishment. But if children die soon after birth, when

the most anxious attention is exerted to preserve them, is it not probable that, in circumstances like those we speak of, the fatal event will be more common? Is it not rather surprising that any should live? The dangers that attend this first state of existence are numerous, and the neglects which may prove fatal are equally so. It is not our present business to point out these; and, indeed, we have through the whole discussion purposely avoided giving information that may be abused. The foreign authors on forensic medicine seem to aim at assisting criminal intentions, by industriously pointing out the means of their execution.

WOUNDS. The surgeon is often called to decide on the degree of injury sustained by these, and on the cause of death which follows them. When not mortal, and mutilation only is the consequence, the recompense which the law awards is proportioned to the injury sustained. The English law, however, makes the lying in wait, to *maim*, a capital offence, and with great propriety, as the lurking assassin is far more dangerous than an open enemy; and when it was alleged in a criminal's defence that the design was to kill, not to maim, the objection was overruled, on the principle that *omne majus continet in se minus*. It is not easy to kill without maiming.

Wounds are fatal either in consequence of the effusion of blood, or the destruction of the organization of some part essential to life. It is not here our business to enter into the legal distinctions in this very complicated subject; but to point out to the surgeon, for his observation, the various circumstances on which these distinctions are founded. The divisions of the civilians, and of the older forensic physicians, into wounds mortal or indifferent, necessarily or absolutely mortal, &c. we shall not enlarge on, as they are not applicable to the system of English jurisprudence. Wounds may, however, be fatal by accident, as a bone at some part of the skull may be penetrated, if peculiarly thin, by a slight blow; a part essential to life may be in a preternatural situation, as a blow on the groin, which would do no injury, may bring on a fatal inflammation in case of a previous hernia; or a fever, which a slight blow has occasioned, may excite an indolent vomica to suppuration. In all these instances, the English law inquires *quo animo* the injury was inflicted. Again, a trifling wound may become fatal during the prevalence of a malignant epidemic, in a constitution deeply tainted with scurvy, syphilis, &c. or in one of great nervous irritability, by inducing tetanus, or its lesser degree, a locked jaw. A state of pregnancy, infancy, or old age, will also render trifling injuries dangerous or fatal.

The event is equally influenced by obstinacy or cowardice, which prevents the treatment necessary to preserve life; by intemperance, violent passions, or despair; by neglecting the proper precautions enjoined; the want of necessary assistance, its delay in inclement seasons, or the unskilfulness of the practitioner. It was a truly judicious remark of a judge in a late cause, that he could not try the skill of a surgeon; and we would here add, that in every case where the opinion of a professional man is called on the conduct of another, he should reflect that his judgment is enlightened by the subsequent circumstances. In the situation in which the first practitioner was at the early era of the accident or complaint, the question must be, could he with

propriety have acted differently? If that question is answered in the affirmative, another will arise; and should a man, himself liable to error, be forward in criminating a brother?

Wounds of the brain are seldom mortal, except the base, the cerebellum, or the spinal marrow at its commencement are injured. A large portion of either hemisphere has been evacuated without injury, and even without the slightest (apparent) diminution of the faculties. Depressions of the skull are much more dangerous; and compression, from a fractured skull or extravasated fluids, as well as that torpid inflammation which concussion, after some time, brings on (vide *CONCUSSIO* and *CEREBRI COMPRESSIO*), are almost equally fatal. It is not the present object to point out the symptoms of each; but we must add the strongest injunctions in case of apparent compression, to examine with the strictest anxiety, the part affected, in order to the application of the trepan. This is often very difficult to ascertain.

Wounds of the nerves are not always dangerous; but if a nerve is partly wounded it may bring on a fatal tetanus, when, from its situation, the nerve cannot be divided. Bohnius remarks, that wounds of a nervous plexus are usually mortal, and bruises on a nervous part, particularly where its nerves are connected with the vital organs, are generally dangerous. Michaelis mentions bruises on the pit of the stomach, in the English pugilistic combats, as frequent causes of death; and indeed, all wounds of the stomach and intestines are highly dangerous, though many miraculous stories are related in which the patients were cured. Wounds of the liver, spleen, kidneys, bladder, and uterus, are also usually fatal, from the access of the air or the internal hæmorrhages. In experiments made on animals each is carefully avoided; but, with every precaution, the Cæsarian section is usually mortal.

Injuries in the vital organs, and indeed all wounds of the larger vessels, must necessarily be fatal. The stoppage of respiration, from any cause, must also soon terminate in death. A question sometimes occurs, whether the person may not have been suspended or drowned after life had been extinguished? This question can only be answered satisfactorily by dissection. Indeed, when life is destroyed by suffocation, the mark of the injury is conspicuous in a much greater degree than by common suspension; and, in cases of drowning, the pale livid colour of the face, with froth round the mouth, may determine the question; but each sign is equivocal. In either case, however, the venous system, particularly of the vena cava, and of the head, is greatly distended; and in strangulation the pulmonary artery is unusually full. Whether death has proceeded from deleterious vapours, in which the body has been confined, to avoid the suspicion of former violence, is not so easily discovered. The application of galvanism would, however, show the extraordinary diminution of irritability, which is usually the effect of such vapours; and, in each case, other marks of violence, and the injury of organs essential to life, will give strong suspicions, which dissection will confirm.

To pursue, with forensic physicians, the wounds of every different part, would extend this article beyond its proper limits; nor indeed could we add any thing which a knowledge of anatomy and physiology will

not supply. We must not suppose our readers ignorant of either.

Shocks and bruises. In the article respecting concussion we have shown how shocks impair the irritability of the vessels, and produce chronic inflammation in the brain or liver, which after some time is often the cause of death. Each cause here mentioned will also produce internal effusions, generally from a rupture of arteries, which may be fatal. A late instance has occurred, in which the radial artery was broken through its whole substance, by the shock only of a fall from a horse; and Pilatre de Rozier, the victim of æronautic folly, fell on his feet, and died immediately from the shock, which was found to produce internal effusions. Blows with a stick, without inflicting any wound, will occasion, internal, and sometimes neighbouring accumulations; and military punishments, when not fatal from gangrene, are sometimes so from abscesses forming *below* the bruised part. (Hamilton's Regimental Surgeon.) It is necessary, therefore, in forensic medicine, to look beyond the immediate injury, and examine the effects of what may arise from the shock or its consequences. In three instances we have heard from practitioners of credit decided testimonies that the blows were not the causes of death, because no mortal appearance attended the wounds. It was unlucky for the cause of justice that they were so ignorant; but humanity might smile through her tears, and charitably hope that the escape would prove a warning.

Hanging and drowning. We can scarcely separate the forensic from the more strictly medicinal consideration of these subjects, and must therefore refer to STRANGULATIO and SUSPENSIO.

MEDICINA POLITICA. Medical interposition, according to our laws, is seldom necessary in questions of police. Yet there are many cases where an intelligent physician might afford satisfactory information. Perhaps the neglect has arisen from that dogmatism which is the effect of ignorance, or of imperfect science, as in the instance mentioned by Dr. Percival, where two physicians contradicted each other respecting the dangers from a copper work. One swore positively it was dangerous; because copper ores usually contained arsenic; the other had ascertained, by experiment, that the ore in question contained none.

In the article AER we showed that weather, and a state of atmosphere apparently the most insalubrious, were sometimes found healthy; and that neither reasoning *a priori*, nor experiment with the eudiometer, would always point out situations where the health can be preserved. The vicinity of marshes certainly renders situations unwholesome; but this is liable to exceptions. If the prevailing winds blow from a marsh to a town, at the season when the marsh is covered with water, little danger arises from it; but if the wind passes over it when in a moist state, diseases often follow. Dilution of the miasma, we have said, is the best security, and, therefore, at a certain distance its power is lessened or destroyed; but unfortunately this distance is not ascertained, nor is it certain that every marsh produces deleterious vapours. Those covered with salt water at each returning tide, or even at each spring, are not always dangerous. We cannot ascertain the innocence of any other kind, except of those very generally covered with water or herbage. Stag-

VOL. I.

nant water has indeed been accused; but we suspect without reason: it certainly is not eminently injurious, and, from the "green mantling," known to exhale oxygenous gas, it may probably be salutary.

Towns, it may be said, cannot be removed; but if unhealthy they will be gradually forsaken. A house may be removed to a healthier spot; but the more temporary situation of a camp or a barrack which may be chosen should be fixed with peculiar care. The reports of army surgeons frequently point out the fatal effects of inattention to this important circumstance; and it has been said that barracks have been heedlessly erected in spots peculiarly unhealthy; nor should we be surprised to find the same carelessness respecting health that we have found of expenditure. A medical topography should be published of every district, comprehending the particulars of its situation, its prevailing winds, usual temperature, and reigning diseases. This plan, which has been adopted in France, would truly merit the attention of the legislature; and it might easily have been appended to the agricultural surveys, were we as attentive to the lives and health of mankind as of the shape or breed of cattle.

Nuisances often claim the attention of courts of justice, and physicians are sometimes called on to decide. Their object is, however, to determine only what manufactures are injurious to health. A brick-kiln, a lime-kiln, a pottery, and an iron-foundry, are unpleasant neighbours; but can we say either is unwholesome? Smelting-houses for lead, and, in general, for copper; dye-houses and tan-yards, erected so near the water as to corrupt the stream, are certainly injurious. The manufacture of the mineral acids, the oxygenation of the muriatic acid for bleaching, the singeing of velvets, currying of leather, are processes always offensive, and generally injurious; for the workmen are usually pale and weak, subject to nervous diseases, and seldom long-lived. Yet it is said, that the improved methods of burning the smoke prevent much of the inconvenience. The process of making candles is offensive, but apparently not unwholesome. It has been admitted into towns, but with reluctance; and the manufacture is discouraged in populous cities when complained of. The business of the dyer or the butcher is certainly not injurious to the health of those who practise or who live near either, nor can we recollect, in a large populous and trading town, any peculiar complaint that could be traced to their quarters. The breath and the dung of the cows have been thought salutary; but should they be so, the vicinity of pigs is certainly otherwise, and these should not be fed in populous cities.

Were the police to interfere in buildings, one circumstance should be indispensable, viz. that every house should have a free ventilation from the front to the back part: the smallest court behind would be sufficient, if not shut up by houses rising gradually higher on a hill. We have found no circumstance so injurious to the general health of a family as a situation where free ventilation is impeded.

The foreign authors on the medicina politica are full of numerous disquisitions, in which the law of this country speaks positively, and requires no medical aid. One of these points is the age proper for marriage; others are cohabitation, the Cæsarian operation, punishments

during pregnancy, &c. One of these subjects calls, we think, for medical interposition, viz. the danger of propagating the most dreadful diseases, as mania, scrofula, phthisis, &c. Yet we see not how physicians can interfere; for the child sometimes partakes of that parent's constitution, which is perfectly sound. Must that child, or such children, then, be deprived of existence because the life of others may be short or suffering? Humanity, reason, and religion, will at once forbid. A stronger case is, where a woman, from deformity, cannot have a living child. Must her marriage be prevented? Neither law nor religion will decide in the affirmative, though the child and the mother may be sacrificed; and such is the circumstance lately mentioned, where the civilians have thought the procuring abortion justifiable. This, for numerous reasons, we must oppose, though we think bringing on labour at the seventh month a humane and judicious expedient: the impossibility of the woman's bearing a living child should, however, be first ascertained without any doubt.

When the testimony of a physician is called for in a court of justice, his evidence should be clear, divested of technical language, and in modest, decent terms. He is sworn to tell the truth, the whole truth, and nothing but the truth; yet we have spoken of giving truth in her fairest garb, of softening what is harsh, and leaning to the side of humanity. We must explain. It is not our design to recommend prevarication, much less concealment; yet in the most decided cases there must be doubts, there must be views, which will carry with them alleviations. It is neither prevarication nor concealment to give each their full force; to point out how far they may bear on circumstances the most apparently positive. It has been said that it is better ten criminals should escape than one innocent person suffer by insufficient evidence. Yet criminals are confessedly punished for the sake of example; and the frequency of escapes, we fear, encourages new attempts. The maxim, therefore, though humane and benevolent, has been carried to an extreme; yet, as involving some intricate disquisitions, not applicable to medical evidence, we can only add, that as the extreme of justice is the extreme of injury, so excess of humanity may be the excess of cruelty.

We have now finished a subject, new in our language, and in which, though we have anxiously avoided error, we may have often committed it. The extent of our article is comparatively short, for we have endeavoured to compress volumes into pages; and as English forensic disquisitions on medical subjects must relate to English laws, many bulky inquiries were foreign to our purpose. Yet, in our references at the end, we have pointed out the sources of a more general and a more extensive inquiry. If these appear numerous, the reader will feel more sensibly the obligation we have endeavoured to confer, viz. contracting our article by the omission of numerous references in our progress. To the candor of the more enlightened and experienced readers we now trust it, with a consciousness of having meant well; of having

*Nothing extenuated,
Nor set down aught in malice.*

MEDICINA STATICA. During the prevalence of the mechanical systems, when *pondere mensura et numero Deus omnia fecit* was the conduct held out to our imitation, the body was constantly weighed, and the salubrity of food was estimated by its perspirability. This plan, pursued at some length by Sanctorius, was soon found to give unsatisfactory results; for the valedudinarian, in his statical chair, though the balance was carefully preserved, lost his strength and spirits; and he saw, with surprise, that he was "truly found wanting." Many circumstances were not taken into the account, which would greatly alter the result; but these we need not stay to enumerate, as the folly has had its day, and is now forgotten.

Sanctorii Medicina Statica, and Keil's Aphorisms.

MEDICINA TRISTI'TIÆ. See CROCUS.

MEDICINA'LES DIES, are those days in fevers which are neither critical nor indicatory, and on which it is supposed proper to administer powerful remedies.

MEDINE'NSIS VE'NA, (from *Medina*, where it was frequent). *Medena vena.* A WORM; called *vena*, before it was known to be an animal. See DRACUNCULUS.

MEDITU'LLIUM, (from *medium*, the middle). See DIPLOE. When it signifies the pith of vegetables it is called also *cardia*, *cor*, *encardium*, *medulla*, *matrix*.

ME'DIUM, (from *Media*, its native soil). See CERVICARIA.

ME'DIUM TE'STÆ. See BREGMA.

ME'DIUS DIGITUS. See DIGITUS.

MEDU'LLA, *quia in medis ossis.* MARROW; *axungia de mumia.* In anatomy it hath various significations. The white substance of the brain is called *medulla*, or the medullary part, to distinguish it from the brown or cortical. The continuation of the brain in the spine is distinguished by the epithet *spinalis*; but *medulla* strictly means marrow in the bones.

If the marrow be viewed through a microscope, it seems a mass of small globules united like those in the roe of a herring. The distinction between *medulla* and *succus medullaris* is useless, for the marrow in the living body is always fluid. The *membrana medullæ* not only lines the internal surface of the bones, but divides the vesicles, or membranous bags, containing the marrow; these very fine minute vessels from which the marrow is secreted are dispersed on these membranes, and are branches from the artery, which enters the bone by its appropriate aperture. The use of the marrow is said to be rendering the bones flexible, for it was with little reason supposed they would soon otherwise become brittle, as happens in syphilitic and scorbutic habits, where it is apparently separated in too small a quantity, too quickly absorbed, or diseased. The *membrana*

medullæ is furnished with a nerve which enters with the artery, and with an accompanying vein. The small vessels which secrete the marrow are more than usually diminished by advancing age; and we thus find the marrow bloody in the earlier periods, oily in the middle stages of life, and watery in old age.

The marrow is never sensible but in a diseased state, and is usually absorbed with the rest of the fat in dropsies. In the fœtus the bones contain albumen chiefly; and in birds the proportion of marrow is inconsiderable, for the cavities chiefly contain air. Marrow of animals is prescribed in some compositions, but it has no superior efficacy to other fats.

MEDU'LLA C'ASSIÆ. The pulp of the cassia fistularis. See also MEDITULLUM.

MEDU'LLA OBLONGATA is a continuation of the medullary substance of the cerebrum and cerebellum, passing downwards, and a little backwards to the foramen magnum occipitale, where it assumes the name of *medulla spinalis*. It is rather of a depressed pyriform figure though called oblong; rising by two crura from the cerebrum, and two peduncles from the cerebellum: the enlargement formed from the union of these is called *pons varolii*, or *tuberculum annulare*, behind which is a stricture upon the medulla oblongata, followed by an enlargement, on each side, styled *cornua pyramidalia*. From the medulla oblongata arises the medulla spinalis, and all the nerves which pass from the head, except the first and second pairs. (See NERVI.) Death is the immediate consequence of an injury on the medullary part. See CEREBRUM.

MEDU'LLA SPINALIS; *cerebrum elongatum*; *Æon*; is the continuation of the medulla oblongata, from the foramen magnum occipitale, through the vertebræ of the neck, back, and loins. It is of different sizes; in the neck flat and broad; in the back, small; in the loins, large; and at last it becomes a bundle of nerves, which have the name of *cauda equina*, because when taken out, and extended in water, they resemble a horse's tail, and as the medulla passes out of the foramen magnum, its external membrane the dura mater is united to the ligamentous lining of the bony cavity, but this connection does not extend beyond the first vertebra. The cineritious matter in the medulla spinalis is within the medullary.

A singular circumstance, of importance in explaining the phenomena of many diseases is, that the spinal marrow, though apparently one cord, is divided into two, easily separated, but united by a *cineritious substance*: it is therefore, double; but, from the mode of union, single only; and we thus see how, in the more important organs, an injury in one part of the marrow is attended with a diminution of the power only in the organ, and can explain the reason of the irreparable consequences of a distortion, or exostosis of the bony canal. The fasciculi of nervous fibrils are sent off from each portion of this double cord, anteriorly and posteriorly, passing through separate foramina of the sheath. The posterior nerves form a ganglion, and then unite with the anterior. Each fasciculus is attended by the external lamina of the dura mater, the internal is gradually lost, and the angle left by each in its first divarication is filled by a fine ligament, which appears to support the nerves on the front, and behind, in their passage. This denticulated ligament seems through the

whole cord to distinguish the anterior and posterior bundles, and, near the cauda equina, has been considered as itself nervous, since it there loses its denser structure as having less to support. The tunica arachnoides is more distinct from the pia mater in the spinal marrow than in the brain, though it adheres more closely to this membrane at the bottom than above. It is apparently suspended by the denticulated ligament, and passes with the dura mater, along the nervous fibrils sent off.

The *spinal arteries* arise from the vertebral within the foramen magnum, which again passing through the occipital hole divide into two other branches, which run to the posterior portion of the medulla. Each runs through the respective grooves formed by the division of the cord. They divide, and again unite and anastomose occasionally, with the vertebral, the intercostal, the lumbar, and sacral arteries. We thus see that the effects of a slight change in the capacity of the bony canal, by interrupting the course of the blood, and, in part the nervous influence, may be gradually obviated by the efforts of nature alone. The medullary veins terminate in the vertebral, and in different sinuses, which have a free communication, apparently serving, as in the head, to keep the arteries full, and to prevent the fatal effects of vertebral pressure. See CEREBRUM.

MEGALOSPLA'NCHNOS, (from μέγας, *great*, and σπλῆγχιον, *a bowel*). A person affected with an enlargement of any viscus.

ME'GRIM. See CEPHALALGIA.

MEIBO'MII GLA'NDULÆ. See CILIARES GLANDULÆ.

MEL, MELI, (from μέλι, *honey*). HONEY; *aeromili*; *acoitus*. Aristæus, a pupil of Chiron, is said to have first gathered this sweet vegetable juice, collected by the bee from the flowers of various plants, and deposited in the cells of its comb. The little animal which furnishes this rich juice is the *apis mellifica*, Lin., and the honey which separates without expression contains a less proportion of wax, and is of a thick consistence, a whitish colour inclined to yellow, a granulated appearance, an agreeable smell, and pleasant taste; both the colour and flavour differ in some degree, according to the plants which the bees prefer; but that wrought by young bees, and permitted to run from the comb without heat or pressure, is called virgin honey. The honey of old bees, pressed from the wax, is yellow. Honey produced where the air is clear and hot is better than that where the air is variable and cold. Where the bee hives are fixed; aromatic plants, particularly thyme, lavender, violets, primroses, baum, sage, and borage, should abound. Honey seems to be merely collected from the flowers, and not elaborated by the internal economy of the insect, for it derives, apparently from its source, many qualities not peculiarly its own. New honey to many proves disagreeably and powerfully laxative; and it sometimes, particularly in America, proves poisonous. Boston (American) Transactions. Each inconvenience is often removed by age, but more certainly by boiling. The animal which collects it is an exclusive inhabitant of the old continent, imported by America, where the natives call it the white mens' fly.

Honey contains a large portion of a purely saccharine matter, mixed with an acid partly uncombined, though concealed by the sugar. With this,

however, there is certainly a proportion of mucilage, since oxalic acid is the result of its treatment with the nitric.

If M. Seguin's late experiments are correct, honey must also contain albumen, since substances which are susceptible of fermentation without yeast, seem, in his opinion, to owe it to their albumen. When deprived of it they lose this property; and when it is again added in the form of the white of an egg, they regain it. Yeast certainly contains albumen, but M. Seguin has lately shown so much fancy in his experiments on gelatine, with which intermittents he thinks may be cured, because the bark appeared to contain this substance, that we distrust his present conclusions.

Honey is highly nutritious, though when long continued as a diet, is said to occasion a dissolution of the blood. As a medicine it is supposed to be aperient, antiseptic, and expectorant: but it is perhaps only slightly laxative, and a pleasing demulcent. It seems to possess some stimulus, since it is forbidden where heat and inflammation are considerable. If given in a large quantity it has been said to relieve asthma, and dissolve a calculus in the bladder (see CALCULUS); but there is much reason to doubt its efficacy in these complaints. It is only a sugar with a larger proportion of mucilage, for its acid is inconsiderable in quantity, and highly volatile.

MEL AE'RIMUM. See MANNA.

MEL DESPUMA'TUM. CLARIFIED HONEY.

Liquefy the honey in a water bath, separating the scum as it arises. On continuing the heat, a considerable quantity of an aqueous fluid, impregnated with the finest smell of the honey arises: the inspissated residuum dissolves in water and in spirit. If treated with moist clay, as practised by sugar bakers for purifying sugar from its treacle, the unctuous parts of the honey may be separated, and its saccharine matter obtained in the form of a solid, saline, white concrete.

OXYMEL SIMPLEX. Simple *Oxymel*. Take of clarified honey, two pounds; of distilled vinegar, a pint. Boil them in a glass vessel, with a gentle fire, to the consistence of a syrup. Pharm. Lond. 1788.

CERA'TUM ME'LLIS, (from *cera*, wax, and *mel*, honey). CERATE OF HONEY. R. Olci olivæ; mellis despumati āā ℥ss. Ceræ flavæ. Emplastri lithargyri āā ℥iv. m. Melt the oil, wax, and plaster together, and afterward add the honey. This cerate is said to be well calculated for scrofulous ulcers, as it is slightly stimulant.

MEL BORA'CIS. HONEY OF BORAX, consisting of an ounce of honey to a drachm of borax, is applied to the mouth in cases of aphthæ.

In every instance where honey is thus employed, it should not be new, and it should be ascertained previous to its use whether honey commonly disagrees with the bowels.

Of many compositions honey forms the basis, as the *mel scilla*, *oxymel scilla*. See SCILLA. *Mel Rosa*. See ROSA. *Oxymel Colchici*. See COLCHICUM. *Mel hydrargyri*, and *Mel Ægyptiacum*. See ÆGYPTIACUM UNGUENTUM.

MELÆ'NA, MELAI'NA, (from *μελας*, black). A disease in which the discharges are black, attributed to black bile. See MORBUS.

MELÆ'NA NO'SOS. See MORBUS NIGER.

MELAMPO'DIUM. See HELLEBORUS NIGER.

MELAMPY'RUM, (from *μελας*, black, and *πυρος*, wheat, because it resembles wheat,) *triticum vaccinum*, *cratægonum*, PURPLE COW WHEAT, *melampyrum arvense* Lin. Sp. Pl. 842, because it is very grateful to black cattle. Its effects resemble those of darnel, and are narcotic, until custom has rendered it habitual. It is found among corn in many countries, particularly Friesland and Flanders. A wild species is called *saturcia lutca sylvestris*. *Melampyrum sylvaticum* Lin. Sp. Pl. 843. See Raii Historia.

MELANAGO'GA, (from *μελας*, black, and *αγα*, to expel). Medicines which purge off black matter supposed formerly to be bile.

MELANCHO'LIA, (from *μελαινα*, black, and *χολη*, bile). MELANCHOLY; *delirium melancholicum*, *erotomania*, *panophobia*, *athymia*. Dr. Cullen places it as a genus in the class *neuroses*, order *vesaniæ*, and defines it, a partial insanity, without dyspepsia. (Vide MANIA.) Melancholy and hypochondriasis are so nearly allied, that the distinction is difficult. Dyspepsia is, however, a commonly attendant symptom of the latter; but absent in the former.

Of this Dr. Cullen distinguishes eight varieties, arising from the objects of false conceptions. 1st, from being fearful of the dangerous state of the constitution; or, 2dly, from a false conception of their more prosperous situation; 3dly, from violent love, without the irritation of lust; 4thly, a superstitious fear of a future state; 5thly, a dislike of motion, and all the offices of life; 6thly, with iniquitude and restlessness; 7thly, with a weariness of life; 8thly, from a man's false conception of the nature of his own species, fancying himself a dog, a horse, or some other animal.

Melancholy, however, is in general the beginning or a less degree of madness, and the highest degree of hypochondriasis. Each passes gradually into the other; and they all often, at last, terminate in alienation of mind. See MANIA.

MELANOPI'PER, (from *μελαινα*, black, and *πιπερ*, pepper). See PIPER NIGRUM.

MELANTHIUM, and MELASPERMIUM, (from *μελας*, and *σπερμα*, semen, seed). See NIGELLA ROMANA.

MELANTO'RIA, (from *μελας*, black). See ATRAMENTUM SUTORUM.

ME'LAS, BLACK. An epithet applied to the colour of the skin, and to some particular medicines, as *calomelas*. A species of leprosy of a dark black colour has the same appellation. See ALPHUS.

MELA'SMA, (from *μελας*, black). See SUGILLATIO.

MELA'ZZO. See SACCHARUM.

ME'LCA, (from *αμελγα*, to milk). "Milk well seasoned with boiling hot vinegar, to separate by rest the curd from the whey." Constantine de Agricultura, lib. xviii.

MELEGE'TA. See PARADISI GRANA.

MELE'OS. See ALUMEN.

ME'LICA. See MILIUM INDICUM.

MELICERI'OLA. A small meliceris.

MELICE'RIS, (from *μελι*, honey, and *κηρος*, wax). *Mellifavium*, is an encysted tumour, whose contents resemble honey and wax. It differs from the atheroma by its evident fluctuation, and from the steatoma by

its firmness. It may be extirpated, or opened and dissolved, by exciting suppuration. See NÆVUS.

MELICRA'TON, (from *μελι*, honey, and *κεραυνομι*, to mix). See HYDRONELI.

MELIGE'ON, (from *μελι*, honey,) a fœtid oily humour of the consistence of honey, discharged from ulcers when complicated with a caries of the subjacent bone. Blanchard.

MELILO'TUS, (from *μελι*, honey, and *λωτος*, the lotus,) *lotus sylvestris*, *sertula comphana*, *trifolium cabalinum*, *corona regia*, COMMON MELILOT, *trifolium melilotus officinalis* Lin. Sp. Pl. 1078, is a plant with smooth, oval, striated leaves, standing three together on slender pedicles, and round, striated, branched stalks, terminated by long spikes of papilionaceous flowers dropping downward, followed by short, thick, wrinkled pods, containing each one or two roundish seeds. It is annual, or biennial, and flowers in hedges and cornfields the greatest part of the summer.

Melilot is emollient, and supposed to be anodyne, participating of the virtue of camomile. Its taste is unpleasant, somewhat acrid and salt, but not bitter; when fresh it hath little smell, but in drying acquires a strong aromatic though disagreeable odour. The distilled water of melilot, though of little smell, remarkably heightens that of other substances. It formerly gave name to a plaster, to which its juice imparted a green colour; but it is now seldom used.

MELILO'TUS MAJOR. See LOTUS URBANA.

MELIPHY'LLON, (from *μελι*, honey, and *φυλλον*, a leaf). BAUM OF BALM. See MELISSA.

MELI'SSA, (from *μελισσα*, because bees are fond of it,) *afiastrum*, *erotion*, *mellifolium*; *citrigo*, *citraria*, and *cedronella*, from its colour; *melissa officinalis* Lin. Sp. Pl. 827, is a well known plant in our gardens: the stalks are square; the leaves are oblong, pointed, dark green, somewhat hairy, and set in pairs, in the bosoms of which arise pale, reddish, labiated flowers, standing several together, on one pedicle, with the upper lip roundish, erect, and cloven, and the lower divided into three segments. It is perennial, a native of mountainous places in the northern parts of Europe, and flowers in our gardens in June.

Baum is one of the mildest cordials and corroborants: with a plesant smell, resembling that of the lemon, and a weak aromatic taste, which it loses in a great degree by drying; a slight roughness discoverable in the fresh herb, becomes more sensible when dry; the young shoots are stronger than the full grown stems. Infusions of the leaves, in water, smell agreeably of the herb, but have not much taste, though, when inspissated, that of the extract is bitterish and austere. Infusions of baum do not, like other aromatics, offend the head. Cold infusions in water, or spirit are far better than the cohobated distilled water, and are the best preparations. It used to be considered as an efficacious nervous medicine in hypochondriasis and melancholia, as well as an emmenagogue. At present it is only given in infusion as a grateful diluent in fevers, sometimes acidulated with lemon juice.

On distilling the fresh herb with water, it strongly impregnates the first running with its grateful flavour. When large quantities are subjected to the operation, a

small portion of essential oil, called *ol. Syriae*, or *ol. Germanis*, swims on the surface. It is of a yellowish colour, and a fragrant smell. See MOLUCCA.

MELI'SSA NE'PETHA. See CALAMINTHA.

MELI'SSA CALAMIN'THA. See MONTANA.

MELI'SSA TU'RCICA, *camphorosma*, TURKEY, or CANARY BAUM, commonly called *balm of Gilead*, *dracoccephalum Canariense* Lin. Sp. Pl. 829. This species is a native of the Canary isles, and scarcely bears the cold of our climate without shelter. It is commended as a warm tonic if frequently drank in infusion.

MELISSOPHY'LLON. See MELISSA, and BALLOTE.

MELITI'SMOS, (from *μελι*, honey.) A linctus prepared with honey.

MELLA'GO, (from *mel*, honey.) Any medicine of the consistence and sweetness of honey.

MELLEGUE'TTA. See PARADISI GRANA.

MELLIFA'VIUM, (from *mel*, and *favus*, honey-comb). See MELICERIS.

MELLITUS, (from *mel*, honey,) sweet, partaking of the nature of honey. This is the trivial name of a species of *diabetes*, q. v. a disease which, since the publication of the second part, has attracted the attention of MM. Dupuytren and Threnard. (See MANNA.) They discovered that the residue of diabetic urine, after evaporation, was not peculiarly sweet to the taste, though it had all the properties of real sugar; while manna, a substance peculiarly sweet, contained sugar only in a very small proportion. They found an animal diet successful, and on examining the urine during the cure, perceived the first salutary change in the urine to be an evolution of albumen, and soon afterwards the urea and uric acid appeared. In the true diabetic urine no animal matter can be discovered.

MELIFO'LIIUM, (from *mel*, and *folium*, a leaf). (See MELISSA.) MELISSOPHYLLUM, *melitis melissophyllum* Lin. Sp. Pl. 832, has been used in calculous complaints, and as an emmenagogue, but is now neglected.

ME'LO, (from its resemblance to *μηλον*, an apple.) The MELON, *cucumis melo* Lin. Sp. Pl. 1436. This fruit is cooling and watery, and should be taken with caution by those who have weak digestive powers, and are best eaten with sugar and some aromatics, as ginger, or pepper. They are diuretic, and have been said to produce bloody urine, which may have happened, but it seems a solitary instance.

ME'LO I'NDICUS. See JACE BRASILIENSIBUS.

MELO'E VESICATO'RIOUS. See CANTHARIDES.

MEL'ON, (from *μηλον*, an apple.) AN APPLE; the CHEEK, (see MALA and BUCCÆ,) or a disorder of the eye, when it protuberates from the socket. See EXOPHTHALMIA and MALUM.

MELO'NGENA, *mala insana*, *solanum pomiferum*. MAD APPLE. It is not injurious, as has been supposed. The Spaniards and Italians eat them both in sauce and in sweetmeats: their taste resembles that of a citron.

MELO'PEPON, (from *μηλον*, an apple, and *πεπων*, a pomepion). The SQUASH resembles both the melon and the pompion, except that its fruit is roundish, striated, angular, cut into five parts, and full of flat seeds, fixed to a spongy placenta. See PEPO.

MELO'SIS, (from *μηλη, a probe*). The searching of any part with a *probe*. See APYROMELE.

MELOSTI'CA PENDULA, Lin. Sp. Pl. 49, is not remarkable for any medical virtues, but its fruit is pickled and eaten as a condiment.

MELO'THRUM. See BRYONIA ALBA.

MELO'THRIS, (a diminutive of *μηλη, a probe*). See APYROMELE.

MEMBRA'NA, (from *membrana, parchment, which it resembles*). A MEMBRANE; *chiton*. Winslow describes it to be a pliable texture of fibres, disposed or interwoven together in the same plane. Membranes differ in thickness, according to the smallness of their fibres, and the number of their planes, called *laminae*. For a description of the *cellular membrane*, see CELLULOSA MEMBRANA, and FIBRA.

The mucous membrane is that covering of the surface of any part, generally within the body, which is exposed to injury from extraneous matter, as the internal membrane of the mouth, nose, lungs, œsophagus, stomach, intestines, and urinary passages, from which they are defended by the mucus, which it secretes.

The common membranes, called the common teguments, are the scarf skin, the true skin, and the cellular membrane; but from this rank the first and last must be excluded, for the scarf skin is an apparently inorganic exudation, inspissated, or a scaly covering, and the *tela cellulosa* not very different. The membranes which cover particular parts are, the *dura* and *pia mater*, *fleura*, *peritonæum*, *pericardium*, *periosteum*, *membrana propria musculorum*, a vascular membrane which covers all the vessels of the body, and those which form the tubes, as the stomach, intestines, arteries, veins, gall bladder, or urinary bladder. Membranes, we have said, (see FIBRA, FÆTUS, and GENERATIO,) are apparently primordial and nervous, and afford a striking instance where nerves, by a closer and more compact texture lose their sensibility; for membranes, like tendons, are insensible in a sound state. They show, however, their peculiar nature by the extreme pain and irritation felt when stretched or inflamed.

MEMBRANA HYALOIDEA, the membrane which encloses the vitreous humour of the eye.

MEMBRANA PUPILLARIS, the membrane which covers the pupil of a fœtus before the sixth month.

MEMBRANA RUYSCHIANA the internal lamina of the choroid.

MEMBRANA TYMPANI. The membrane separating the tympanum of the ear from the meatus externus. (See AURIS.) It is said to consist of six laminae, 1st, a production of the epidermis; 2d, of the skin lining the auditory passage; 3d, a cellular membrane supporting reticulated vessels; 4th, a production of the periosteum of the meatus; 5th, like the 3d; 6th, a production of the periosteum of the internal cavity. Muscular fibres have also been discovered in it.

MEMBRANA'CEI, (from *membrana*). Inflammation of membranous parts.

MEMBRANA'CEUS, (from *membrana*), belonging to the MEMBRANES. In botany it means those leaves which have no parenchyma between the surfaces.

MEMBRANA'CEUS PINGUIS. See CÆLIFLOS.

MEMBRA'NÆ. See INVOLUCRA.

MEMBRANOLO'GIA, (from *membrana*, and *λογος, discourse*). MEMBRANOLOGY. It treats of the common integuments, and of particular membranes.

MEMBRANO'SUS MU'SCULUS; from its large membranous expansion. See APONEUROSIS.

MENDO'SA SUTU'RA, (from *mendax, counterfeit*). The squamous suture in the skull; differing from other sutures, as it resembles a scale instead of being indented into the adjoining bone.

MENDO'SÆ COSTÆ, (from the same). See COSTÆ.

MENINGES, (from *μνω, to remain*). See DURA MATER.

MENINGE'Æ ARTE'RIÆ, (from *μηνιγξ, a membrane*). See DURÆ MATRIS ARTERIÆ.

MENINGOPHYLAX, (from *μηνιγξ, a membrane*, and *φυλασσω, to guard*). An instrument described by Celsus, lib. viii. cap. 3, contrived for guarding the membranes of the brain, whilst the bone is rasped, or cut, after the operation of the trepan.

MENIN'X, (from *μνω, to remain*). See DURA MATER.

MENORRHA'GIA, (from *μηνια, the menses*, and *ἰσχυρμι, to break out*). EXCESSIVE or EXTRAORDINARY DISCHARGE of the MENSES, *metrorrhagia, hæmorrhagia uterina*. Dr. Cullen places this disease in the class *pyrexia*, and order *hæmorrhagia*, which he defines pains of the back, loins, and belly, similar to those of labour, attended with a flow of the menses, or of blood from the vagina, more copious than natural. The species are:

1. MENORRHA'GIA RUBRA. See MENSES.

2. MENORRHA'GIA ABORTUS; *menorrhagia gravidarum*. See Floodings under ABORTUS.

3. MENORRHA'GIA LOCHIALIS. See LOCHIA.

4. MENORRHA'GIA VITIORUM; when the appearances of the menses are from ulcer or other local defect.

5. MENORRHA'GIA ALBA. See FLUOR ALBUS.

6. MENORRHA'GIA NABOTHI; the serous discharge from the vagina during pregnancy.

MENORRHA'GIA DIFFICILIS. Difficult or painful menstruation. See MENSES DEFICIENTES.

ME'NSA. The second lobe of the liver in ancient authors. See AURIGA.

ME'NSA JO'VIS. See VERBENA.

ME'NSES, (from *mensis, a month*), *catamenia, menstrua, emmenia, gynœcia*, periodical discharges of blood from the uterus, vagina, or both, from about the age of fourteen to about fifty. In warm climates they appear at about eight or nine years of age; in temperate ones at thirteen to fourteen, and in the arctic regions not till nineteen or twenty. The quantity discharged is from four to ten ounces; but in this there is much variety, and the discharge continues from two to eight or ten days. In some relaxed constitutions there is occasionally not more than a week's interval, and in general the more lax the constitution, the larger is the discharge, and the longer its continuance. The indolent, the sanguine, and the luxurious, have generally a large periodical evacuation. Usually, the earlier the period when they first appear, the sooner they disappear. In this country they disappear about the forty-fifth year, though, from accidental circumstances, the cessation may happen in the thirty-sixth or be protracted to the

fiftieth year. We have known instances of their continuing to the fifty-second, when they have *not* appeared at a late period. The tales so frequently detailed of their returning at the ages of sixty, and even of eighty, do not merit any particular attention, though often well founded: for in these cases, the discharge is truly hæmorrhagic, generally temporary, and often critical.

The menses flow chiefly from the uterus, and occasionally from the vagina alone, as happens sometimes during pregnancy. When the natural discharge is stopped, a vicarious bleeding takes place from the nose, the lungs, the nipple, the hæmorrhoidal veins, the stomach, the bowels, and even the gums, without any particular inconvenience.

Before that peculiar state of irritability which disposes to an irregular balance of the circulation, and consequently to topical congestion, had its full weight in our physiological and pathological inquiries, a discharge of blood implied, in the opinion of pathologists, plethora. That a general fulness was the cause of the menstrual discharge was scarcely doubted by the soundest physiologists, for the fancies of the lunar influence and of fermentation were soon rejected. This opinion had undoubtedly many observations to support it. The access of the catamenia was marked by general load and oppression; the breasts swelled; the stomach was often disordered; and their suppression was followed by other sanguine discharges. Yet the acuteness of modern philosophers soon discovered that these views would not explain all the various phenomena. They saw that the catamenia continued to recur notwithstanding the system was exhausted, that the fullest habits had not, invariably, the most copious or frequent discharges; for, on the contrary, these were usually observed in the weak and irritable. They perceived also, that a copious general bleeding would not stop their appearance, and the most copious discharge would not always relieve any internal inflammation. If also this view was correct, why did not the catamenia occur at other ages, when the vessels were distended? why not in the intermediate periods, if the arterial system was unusually full? The partial congestions, suggested by the writers of the Stahlian school, came therefore to their aid. The topical load, in a system so irritable, and so generally sympathizing, as that of the uterus, would produce equal uneasiness; from the peculiar sympathy between the uterus and the breasts, the mammæ would swell; and, when any the most purely topical discharge was suppressed, other irregular determinations were known in other instances to come on. Nothing appeared, therefore, to be inconsistent with topical plethora; and this satisfactorily explained all the difficulties of the former system. The idea had loosely floated in the minds of many physiologists before the time of Dr. Cullen; but to him we are indebted for its expansion into a system at once elegant and correct.

In different parts of this work, and particularly in the article of HÆMORRHOIDS, q. v. we have explained the gradual development of the different parts of the body from the distention of the arterial system, ultimately depending on the progressive changes of the relative degree of resistance in the coats of the arteries and veins. The genital systems of either sex

experience this change about the same time, and as the vessels of the uterus easily admit of considerable dilatation, congestion is the consequence, which is relieved by the exhaling arterics yielding to the impulse. No rupture of the veins or arteries takes place, for the discharge is steady, regular, and seldom considerable in a given time. After it has continued for even a short period, every inconvenience is removed, the previous load is no longer felt, and the fulness of the mammæ subsides. The continuance of the discharge is different in different constitutions, but it usually continues from three to five days, when it ceases, sometimes leaving a serous discharge for a day or two, sometimes a mucous one, which, if it continues, constitutes the disease called *leucorrhœa*, or *fluor albus*.

The recurrence of the catamenia is with more difficulty explained. Women, from the sedentary life which they lead, and from a looser contexture of vessels, are more subject to plethoric congestions than men, and the uterus is, from its structure, more likely to receive these accumulated fluids. By degrees, these topical congestions become habitual, and recur independently of any real general plethora. This explanation appears to be supported by the irregular returns of the catamenia in the earlier periods, and the irregular continuance of the discharge before the habit is established. Why the accumulation should require a lunar month before it is equal to produce the effect, it is impossible to ascertain, as why the period of fourteen days should be most commonly required to produce the crisis of fever, or why the seventh and the fourteenth year should be marked by striking changes in the constitution. Such is the determination of Him "in whom we live, and move, and have our being."

This view of the subject will explain equally the pathology and practice in all their varieties. When the changes, which successively take place in the determinations to the different parts, commence, a great degree of irritability occurs, and sometimes considerable debility. This is particularly the case with the changes in organs so peculiarly irritable as those connected with generation. At this period, in young women, we find a pallid languor, want of appetite, terrors, tremors, and even convulsions. Where the constitution is more robust and plethoric, violent pains, flushings in the face, and even feverish attacks. In the first instance, the determination is unequal to the task, in the second, some obstruction occurs in the exhalents; and, like every other impediment to the free circulation, excites a vis a tergo to overcome it. Similar symptoms follow obstruction, joined with the inconveniences which arise from the stoppage of an habitual discharge, added to those which result from the altered determination, which is the consequence.

MENSES DEFICIENTES, the amenorrhœa of Dr. Cullen, including also, with less accuracy, the dysmenorrhœa, difficilis menstruatio of authors, constitute a disease divided into the *amansio* and *suppressio mensium*. The difficult menstruation may be a variety of the latter, as the discharge is temporarily suppressed.

The *emansio mensium* consists of a retention of the discharge at the period when it should take place, independent of pregnancy. To constitute a disease it must be attended with pain, uneasiness, or a disturbance of the functions, for, whatever time may

be fixed as the usual one, this period is protracted in some constitutions, without inconvenience. Much depends on the climate, the mode of life, the structure of the body, and the peculiarities of the constitution. Thus in a warm climate the period may be accelerated to the age of ten or eleven, and, in a cold one, retarded to eighteen: a girl, indulged in all the luxuries of modern fashionable life, and the sedentary seamstress, or the laborious peasant, experience equal prematurity, or retarded expansion: a full bodied plethoric girl and a thin attenuated one, with small delicate limbs and a torpid circulation, are respectively in the same circumstances. Somewhat depends also upon structure. In the case recorded in the Edinburgh Journal, where the menses never appeared, the ovaria were wanting. In similar circumstances, the form, the manners, and general appearance, resemble that of a man; so that, when we see the masculine manner and growth, it is highly probable that the menses, if they appear at all, will be scanty, and impregnation improbable, as the female structure is in some important respect defective.

When the discharge does not take place, the whole system becomes languid, the complexion pale, the mucous secretions are defective: and, in consequence, the fœculent discharges are impeded, and the nose is dry. The appetite is bad, or fanciful, often requiring substances not alimentary, though not, as has been said, always antacid, nor in such circumstances does acid abound in the stomach. The mind is whimsical and variable, the voluntary muscles convulsed; the sleep disturbed, the urine pale. In fact, the animal functions are almost wholly suspended, and the vital ones feebly carried on, for the pulse is low and quick, the breathing laborious, consumption, or palsy, seems to impend, and the patient appears to sink rapidly to the grave. In the worst stages of these complaints, a little mucous or serous discharge, perhaps somewhat coloured, changes the scene, and gives some appearance of returning health: it recurs at distant and irregular intervals, attended, each time, with some amendment of all the symptoms, till at last, colour, appetite, spirits, &c. return; and the palid, chlorotic girl becomes a blooming, healthy young woman.

While we are ignorant of the first principles by which nature acts, we know not the impediments to her action. We recognize, in the case before us, either a want of energy, or some resistance in the exhalent arteries; each attended by an apparent sinking of the more active powers. If we observe the progress, the change at last appears to take place from the vessels yielding, in consequence of debility, rather than from increased impetus, for the first appearances, the serous or mucous discharges are complaints, which, at future periods, arise from debility only. The change, though imperfectly taking place, is attended with beneficial consequences; and the powers of nature, thus reanimated, gain additional force, to complete the more perfect state. The regular return, however, is not yet observed, for this is the consequence of habit.

In this weak state young women often continue for many years; but we know not that the complaint has ever been fatal, for, if the discharge does *not* take place, they recover some share of strength and activity. The complaint is often taken for consumption, and many

remedies of a secret kind have acquired credit from the efforts of nature alone. Many old women's remedies have, on the same ground, been highly praised; and the numerous female pills, so often advertised, have appeared to succeed, when nature has done the work. We mean not to deny that this often happens in regular practice, but the foundation of the plans in this disease, we shall proceed to explain.

The most obvious idea in these circumstances is to give strength and activity to the circulating system: another, though a subordinate one, is to relax either a supposed constriction, or to stimulate, topically, the neighbouring vessels.

To give strength and activity to the circulation is attempted generally by tonics and stimulants. Such, however, of the former as combine astringency are supposed to be injurious. The simple bitters are, therefore, often employed, particularly the camomile flowers, and the columbo root. The myrrh is a medicine of a more doubtful nature; and, as a narcotic bitter, may appear to combine a sedative power. It seems, very certainly, to lessen hectic exacerbations. Whether it has a peculiar power in promoting the menstrual discharge we dare not say. We never have observed such power, but have suspected, in hectic, where there is a tendency to hæmorrhage from the lungs, that it has contributed to promote hæmoptysis: it may, therefore, have a similar effect. Astringents have been accused of checking the discharge, and we believe with reason. They have been certainly injurious when employed too freely in critical menstruations, and in puerperal profuvia.

The tonics most generally beneficial are the metallic. Of these the most useful, or rather the most used, are the iron and mercury. We have said, that perhaps, with the exception of lead, all the metallic bodies were tonics, but that the two, just mentioned, seemed to give a more decided activity to the circulation, and that the former even occasioned inflammatory action. Iron, or rather, as it is styled inaccurately, steel, is the foundation of the more common boasted panaceas for this complaint, and is often highly useful. Every form has been in turn extolled, and each has perhaps succeeded. We know not that art has contrived a better preparation than the scales found around the anvil, in a blacksmith's shop, or the green vitriol; and whatever iron can effect will be found to result from these remedies. The chalybeate mineral waters are also frequently used with success. Zinc has been occasionally employed, but we believe no other metal in the later periods, since the cordial and diaphoretic powers of gold and silver have been distrusted. Perhaps arsenic might succeed; but the long time required for the continuance of remedies for this complaint will suggest the most suspicious caution respecting this metal. Cold bathing has been sometimes employed for this purpose, but not so frequently as it might, and probably would have been, were not cold considered among the causes which retard menstruation. We have, however, often found it an useful remedy.

The chalybeate mineral waters have been, us usual, rendered more effectual by exercise, change of scene, cheerful society, and pleasing objects; for all assist greatly in producing the change in the constitution

which facilitates the discharge. Indeed, every thing which establishes the general health, and gives vigour to the constitution, contributes to the same salutary object.

The stimulants employed to give energy and activity to the circulation must be those which act steadily and with moderation, so as not to exhaust the excitability they are designed to support. The chief of these is warmth, rather of climate than the artificial warmth of fires, though these are sometimes of use when combined with exercise; and the patients in an hospital, who soonest receive relief, are those employed in the kitchen. In other forms, heat has been employed as in warm bathing, particularly in the waters at Bath; and more partially in the semicupium and pediluvium; but this remedy is, in general, better adapted to cases of suppression. The exciting passions, as joy, particularly from an object attained, exercise of every kind, warm generous food, with the moderate use of wine, frequent friction, particularly of the lower extremities, electricity generally employed by sitting on the stool, and perhaps Galvanic shocks, may be useful. Breathing oxygen air seems not to have been employed; yet, as increasing the activity of the circulation, and giving the blood a more florid colour, it promises success.

The internal stimulating remedies are various. Of these the most useful are emetics, on the principles already explained in that article. The ammonia; the animal oil of Dippel; the petroleum; the balsam of Peru; guaiacum, and the more irritating cathartics, are employed.

The cathartics, however, most advantageous, are those which act on the rectum, and *topically stimulate* the organs adjoining the uterus. The chief of these is the aloes; and, as costiveness is among the symptoms, so it is best relieved by this medicine: in fact, aloes has a great share in all the secret remedies. Cantharides, as stimulating the bladder of urine; turpentine, as affecting, in the same way, the kidneys, and perhaps the urinary organs through their whole track; and black hellebore, which strongly irritates the whole of the intestinal canal, are useful remedies of the same kind. Shocks of electricity, passed through the pelvis, are said to have succeeded; and cupping glasses have been applied to the sides and the thighs, to invite a larger proportion of the circulating fluids to these parts. The effects of the rubia tinctorum we do not know: it is enough to mention, in any part of this article, that it has been recommended.

We mentioned, among the exciting passions, the attainment of any object; and if this be the object of love, the effects are stronger; and matrimony is generally supposed to be an effectual cure. Yet this disease checks every warmer passion; and, except in peculiar circumstances, the chlorotic girl scarcely looks forward to the wedded state as an object of desire.

In our description of the symptoms, we remarked, that the uterine vessels yielded apparently from debility; and there are many circumstances which concur in proving that some degree of spasm in the weak chlorotic state prevents the discharge. The subject of spasm, as connected with debility, has been sufficiently considered under the articles *CONVULSIONES* and

FEBRIS, q. v.; and, though the connection be admitted, yet the one is by no means a necessary consequence of the other. There are, however, several medicines recommended in the *emansio mensium*, which must chiefly act in this way; among the rest, sitting over the steams of warm water is considered as highly useful. We shall find this remedy particularly so in suppressions, where spasm is more decidedly obvious. The fetid gums are of this kind; and other fetids, as rue, savine, castor, musk, and ambergris, have been recommended. Camphor, which is highly useful, where spasm is certainly the cause, has been recommended in the chlorotic state, and perhaps the myrrh, with some other narcotic bitters, will be chiefly useful as antispasmodics.

Though these are the usual symptoms of that variety of deficient menses, attended with debility, and usually styled the chlorotic state, yet, in some instances, there are considerable fulness and pain, returning at irregular intervals, with vicarious discharges of blood from other organs. As such cases are, however, more common from suppression, or difficult menstruation, we shall speak of the proper remedies under these heads.

SUPPRESSIO MENSIIUM. When the habit is established, and the discharge continued monthly from this cause, it cannot be broken with impunity. The most frequent causes of suppression are exposure to cold, frights, falls, sometimes fever, anxiety of mind, or confinement. Suppression from falls is a peculiarly obstinate disorder, and the discharge is seldom restored; for, as in other shocks, the irritability of the vessels is apparently injured. The attack of fever is often attended with the appearance of the catamenia, and this, if at or near the regular period, is a favourable symptom. If at the intermediate part of the interval it is less favourable, though it affords no dangerous or fatal prognostic, as some practitioners have alleged: suppression in consequence of long fevers is from weakness only, but the return is often protracted. We have thought, that, when the menses appear, on the attack of fever, out of their usual period of recurrence, the following suppression has been more obstinate. In general, the return of the discharge, after any violent degree of either cause, must not be soon expected. Suppression in weak, delicate habits differs little, either in symptoms or remedies, from the species of *emansio* first described. In plethoric habits the symptoms are very different. If the cause occurs during the discharge, a feverish attack often supervenes, the face is flushed, the eyes red; pains in the head and back come on, with sometimes a bleeding from the nose. If a similar cause, occurring in the intervals, is continued in its effects to the usual period of its appearance, symptoms of the same kind are observable; and they recur at each expected return, gradually, however, declining, till the chlorotic state comes on. In general, the sudden causes bring on the inflammatory, those more slow in their action the chlorotic, suppression.

It has been usual, in cases of inflammatory suppression, to bleed copiously, and this is sometimes necessary, to prevent a vicarious hæmorrhage either in the brain or lungs; but, if it can be avoided, we shall also avoid the danger of establishing a new and dangerous habit. We gain much, in such complaints, by determining the

fluids to the skin, by the relaxing diaphoretics; and the sedative, or antispasmodic power of camphor renders it a valuable medicine in this complaint. With either the antimonials, or with camphor, opium is also highly useful; nor should the practitioner neglect to invite the circulating fluids to the hypogastric region, by interposing active purgatives. About the period of the expected return, a smart emetic will prevent the recurrence of the spasm, especially if followed by the camphor, with opium; and the discharge will appear with its former regularity. It sometimes happens, that at the usual period of the return a fever comes on, which, as none of the causes of suppression had preceded, or at least been observed, is usually considered as a common fever. If, however, it is at the period of menstruation, a circumstance which every prudent physician will keep in view, and the fever is of the inflammatory kind, it is highly probable that it proceeds from some spasmodic obstruction in the uterine vessels, and must be treated according to the directions already detailed.

The *DYSMENORRHŒA*, or *MENSTRUATIO DIFFICILIS*, is a similar disorder, and a very important one, as it prevents the completion of the anxious wishes of those "who love their lords." The pain, on the occurrence of the discharge, is peculiarly violent; accompanied often with an obstinate constipation, or a suppression of urine. In fact, until the spasm of the uterine vessels is relieved neither the kidneys nor the bowels yield, however powerful the medicine; and the violence with which each returning discharge is attended, loosens the hold of any embryo, which, in the interval, may have been attached. No disease is more distressing in its symptoms or its consequences; and the regularly returning confinement is disguised by a variety of ingenious inventions, while the consequences in advanced life are all the diseases of celibacy. The remedies are those of suppression, attended with violent pains, but the *dysmenorrhœa* does not require bleeding. An active laxative at the expected period of the return, followed by a full dose of camphor and opium, will often succeed; and, if repeated at the next period, seldom fails to induce the discharge without the preceding pains. When these have been once and again conquered they seldom recur. In the inflammatory suppression and *dysmenorrhœa*, *pediluvia*, and sitting over the steams of warm water, are highly useful. The warm bath, raised to the heat of 94° or 96°, and continued so long as to produce slight faintness, will be often successful; but the laxatives, joined with the relaxants, are not only conducted with more ease, but more certainly effectual.

In the whole of this consideration it will be obvious, that the great object is to correct the deviations from health. When the healthy state is restored, the discharge will return. Medicines therefore should not be too frequently nor too constantly employed; and, on the other hand, too much should not be trusted to nature. It requires a minute discrimination to determine when art should interfere, and how long artificial means should be continued. If our exertions are too violent, the constitution will sink under the double powers of the disease and the medicine: if we are too remiss, the obstruction gains force, and years are required to restore the tone and the general health.

There is, however, a period when the discharge will naturally cease. It is not that the constitution does not supply the fluids as before, but that the diminished irritability of the vessels, or the diminished resistance of the veins, no longer permits the hæmorrhagic effort. This critical period of the female life, *MENSES CES-SANTES*, must be attended to with care. The future health depends in a great degree on our conduct at this time; and we are required to be peculiarly attentive, as female prejudices lead them to attribute every future complaint to some error at this time. The disappearance of the catamenia is preceded by a temporary suppression, continuing perhaps for two or three months, followed by an increased, and unusually continued, discharge. The discharge will sometimes recur at very short intervals, and in profuse quantities, leaving, when absent, a considerable degree of leucorrhœa. The increased evacuation is not always attended with proportional debility, nor the temporary suppression with the symptoms already described. The blood, in these instances, is apparently poured from ruptured veins, without any hæmorrhagic effort. In this way the change is effected, often without disease, and almost unobserved; but the suppression is sometimes attended with general load, with headach and wandering pains; and the excessive discharge with considerable debility. Generally speaking, however, art should seldom interpose. The whole is the work of nature, which, as we cannot imitate, we cannot always assist. Experience, however, in the former variety, goes hand in hand with popular prejudice, and the general fullness is successfully relieved by laxatives. The domestic remedies are not, however, usually well chosen. Women, attached to their early experience, prefer the aloes, in their warmest preparations, but the object is to lessen the proportion of fluids in the abdominal vessels, and whatever effects this purpose with the least irritation succeeds best. The salts alone are in general too cold, but they may be warmed with the tinctures of the more active purgatives, as of senna, rhubarb, or jalap. These, with the relaxant diaphoretics at night, particularly camphor and opium, will restore the circulation to its proper balance without inconvenience.

The task is more difficult when the discharge is immoderate; for female prejudice demands our active interference to check it, but this is always injurious. Young practitioners are commonly alert to show their skill; but it is wiser to rest, and to observe with care. In general, we have seldom known a more healthy old age than in those where the menses have disappeared with these profuse evacuations. If the woman has confidence in her medical attendant, she will remain at rest, in free air, lightly clothed, without exciting the circulation by aliment too rich, or drinks too stimulating; keeping, with anxious care, the bowels free by the most cooling laxatives. This conduct should, we think, be pursued, even when the debility is considerable; nor should even opiates be interposed, except the pain is violent. In such cases, powerful astringents are highly injurious, and we have more than once seen apoplectic attacks from their imprudent use. In a few instances we have found it necessary to regulate the discharge, but seldom with advantage, and have had reason to suspect scirrhusities of the uterus, ulcers

and cancers from the imprudent use of styptics. If called on, it is necessary to attempt relief in some way; and we have generally found, that, though no hæmorrhagic effort is perceivable, we have done more service by cooling and sedative medicines than by bitters and astringents. Bitters may indeed be frequently allowed, and they will please, because an astringency is supposed to accompany every medicine of this kind.

The MÆNORRHAGIA, MENSES IMMODIÆ; or an excessive menstrual discharge, independent of the pregnant or puerperal state, is truly an hæmorrhage, and may be either active or passive. The active hæmorrhagia arises from cold, from blows or shocks, and almost exclusively occurs in strong robust habits. The passive mænorrhagia arises from debility of the vessels, too fluid blood, from frequent miscarriages or labours, which occasion local debility. There is, however, an intermediate kind, viz. the excessive discharges, which occur in the indolent and luxurious females of polished life. In these the vessels yield to excessive fulness, in part from debility, but generally with the assistance of some hæmorrhagic effort. In the first variety bleeding is sometimes necessary, though, as usual, a suspicious and uncertain remedy. It must, however, be often used, to prevent immediate bad consequences; but, in general, rest, in a cool free air, with nitre and camphor, very generally with opium, often in large and repeated doses, interposing cooling saline purgatives, will relieve the complaint. The treatment of the second variety differs in no respect from that of other passive hæmorrhages; but the third often baffles our best endeavours. It is difficult to induce the patient to avoid the principal causes, indolence and luxury; and to constrict distended vessels is the surest means of increasing their debility. If, however, she be obedient, lessening considerably the quantity and quality of her aliment, using, at the same time, free exercise in the open air, she will soon find a degree of languor and debility superior to what she before experienced; and it will be difficult to persuade her to continue a disagreeable plan, when her feelings tell her that increased weakness is the consequence. The fact is, that the diminution of the fluids lessens the tension of the vessels; and, as in the parocentesis, and numerous other cases, the diminution of tension produces faintness, and sometimes even convulsions. It will require, then, no little confidence in the physician, and no common resolution to persevere; yet, with perseverance, relief is certain. To steer between opposing prejudices and the best means of relief is difficult; nor do we know what rules to offer. The disposition of the patient must be consulted, and every address employed to lessen the powers of the aliment; to increase the discharge of the bowels by cooling laxatives; to lessen the activity of the circulation by opiates and refrigerants, while by every artifice bodily exercise is promoted. In the summer, sea bathing, and in the proper season, Cheltenham, and other saline chalybeate waters, may be advised, as change of scene will lead to more frequent exercise in the open air. The fashionable physician, who is contented with receiving his daily fee, while he humours the fancies of his patient by some useless placebo, has the best chance of gaining credit in these cases; as usual, not by assisting, but by pleasing.

Yet some political advice will not be without its

advantage. Women look to the period of the access and departure of the catamenia, as well as the monthly recurrence, as times of peculiar delicacy. They are unwilling to take any medicine unless it be consistent with their present circumstances, and are apt to attribute any disappointment to the medicine that they may have been prevailed on to employ. The discharge is, however, an occurrence which we cannot always produce, and which we can seldom prevent, or supply by any vicarious evacuation. In general it requires no peculiar care; but, while popular prejudices exist against the use of any medicine at this time, a prudent physician will forbear to press it, unless absolutely necessary. If it be so, the inconvenience, whatever it may be, must be met, and every bad effect may be obviated by caution. Even a copious bleeding will often not stop the discharge; purgatives will assist it; and opium, though it may occasionally retard, will be ultimately injurious. When, however, the discharge is fully established, and has continued twenty-four or forty-eight hours, the danger of checking it, even in female apprehension, is inconsiderable.

See Medical Observations and Inquiries, vol. v. p. 160; Hoffman's Medicinæ Rationalis Systema; Haller's Physiology; Cullen's First Lines, vol. iii. p. 9. 32; Hamilton's Midwifery, edit. 4th, p. 134; Edinburgh Medical Commentaries, vol. v. p. 119; London Medical Journal, vol. v. p. 183. The works professedly on this subject are, however, unsatisfactory and erroneous. The various authors on midwifery, particularly Dr. Hamilton, in his Elements, afford the best assistance.

ME'NSIS PHILOSO'PHICUS. A PHILOSOPHICAL or CHEMICAL MONTH is sometimes confined to three days and nights, at others to ten, thirty, and even forty days.

ME'NSTRUUA, (from $\mu\epsilon\nu$, or the Hebrew term *meni*, a month). The menses in women, and the bleeding piles in men. The plural also of MENSTRUUM, q. v.

ME'NSTRUUM, (from the same). A fluid body capable of reducing a given solid to the same state, and thus diffusing the latter through every part of the former; called a *menstruum*, because the chemists first assisted its action by a moderate fire for a philosophical month; synonymous with *solvent*. See SOLUTIO.

MENSURA. The variety of measures employed by different nations renders medical directions often obscure, and occasionally fallacious. The word *mensura* is sometimes employed absolutely to denote a given bulk, and the measure occasionally contains one, sometimes two, quarts, and the quadrans *mensuræ* is either six or twelve ounces. The great diversity in this respect has induced the London college to order every thing by weight; for a pint of the purest alcohol is very different from even a pint of water, and much more so from a pint of the vitriolic acid. In general, the pint is supposed to be equivalent to a pound; but, in medicinal directions, it is estimated at twelve ounces: the French pint is double, and the Scotch pint equal to two quarts. The cantharus of the Swedes equals five pints.

In smaller quantities, the tea spoonful is estimated as equal to a drachm, but few tea spoons hold more than forty drops. A dessert spoon holds somewhat more than than two drachms, called, in prescriptions, *cochlear medium*, and the table spoon about half an ounce.

The modern French weights and measures are greatly

changed, and have produced no little confusion in medicine, chemistry, and even in common life. We shall detail the principles of their new system under the article PONDERA, on which that of their measures depends; so that we shall in this place only explain the terms. The fundamental measure, the LITRE, filled with distilled water, is equivalent to the Paris pint, somewhat more than two English pints, and, in weight, is nearly equal to the kilogram, two pounds. The SEMILITRUM (demilitre) is equal to somewhat more than a pint; the DECILITRUM to about three ounces, and a drachm, equal in weight to the hectogram: the double and the half of the decilitrum are easily estimated. The litre contains fifty cubic inches, and consequently the centilitrum half a cubic inch; and the double centilitrum one cubic inch, or nearly five drachms, about a large table spoonful.

MENTA'GRA, (from *mentum*, the chin, and *αργα*, a disease,) IMPETIGO. An obstinate tetter, which appeared in Italy during the reign of Claudius Cæsar, beginning upon the chin, extending itself over the face, and descending to the neck, breast, and hands. A cautery was applied to some convenient part, so deep as to penetrate to the bone.

We sometimes find a disease of less virulence which seems to merit this appellation. It affects the bulbs of the hair on the chin, resembling, in its nature and treatment, the tinea capitis.

MENTA'LES, (from *mens*, the mind). Alienation of the judgment, in which the functions of the mind are disturbed.

Nosologists have formed a class of diseases under this title, and in an arrangement from symptoms it may probably be admitted. It is, however, necessary to remark, that, though the mind be affected, a læsion of any function, which alone constitutes disease, can only be recognized by the practical physician; and we have found changes, in appearance most purely mental, arise from a material cause. Our idea of the duration of time, for instance, is, as we shall see, produced by opium; a fit of apparent insanity will be relieved by discharging a very moderate quantity of bile. See MANIA.

ME'NTHA, MINT; *hedyosmos*, from its sweet smell; is a perennial herb with square stalks, serrated leaves set in pairs, and spikes of monopetalous flowers, each cut into four sections, and followed by four seeds inclosed in the cup. The species are numerous, but not hitherto described with sufficient accuracy. See Linnæan Transactions, vol. v. for an account of the British species by Dr. Smith.

ME'NTHA AQUA'TICA, Lin. Sp. Pl. 805, *sisymbrium sylvestre*, *mentha rotundifolia palustris*. RED WATER MINT. Its leaves are somewhat oily, and set on pedicles; the stamina long, standing out from the flowers.

ME'NTHA CATA'RIA; *nepeta cataria*, *mentha felina*, *herba felis*, *calamintha palustris*, *nepetella*, *nepeta cataria* Lin. Sp. Pl. 796, for cats are so delighted with the smell that they roll on it, and destroy the plant unless defended till it has acquired some strength. It is an hoary plant with square stalks; the leaves heart shaped, acuminate, serrated, and set in pairs on oblong pedicles; the flowers whitish, labiated, standing on spikes at the top of the branches. The upper lip is divided into two, and the

lower into three, sections. It grows wild in hedges and on dry banks, and flowers in June; is moderately aromatic, of a strong smell, resembling a mixture of mint and pennyroyal, and participates of their virtues. Water dissolves their active matter; but rectified spirit extracts it more completely. Distilled with water, they yield a yellow essential oil, not quite so agreeable as the herb, though resembling it in smell: the remaining decoction is bitter and subastringent. See Raii Historia Plantarum; Cullen, Lewis, and Tournefort's Materia Medica.

ME'NTHA CO'RYMBI'FERA MI'NOR. See AGERATUM.

ME'NTHA CRISPA, Lin. Sp. Pl. 805, agrees in its general virtues with the MENTHA SPICATA, q. v.

ME'NTHA HIRSUTA, var. δ . Smith, in the Linnæan Transactions, v. 196; probably a variety of the mentha sativa. See FLORA BRITANNICA.

ME'NTHA PALU'STRIS FO'LIO OBLO'NGO, *mentastrum hirsutum*, *auricularia*; HAIRY WATER MINT, or EARWORT, has long hairy leaves, without pedicles, and broad spikes of flowers. All the water mints grow in marshes and on the banks of rivers, and flower towards the end of summer; their smell is less agreeable than that of spear mint, their taste more bitter and pungent: the second sort resembles the pennyroyal. They yield much less essential oil than the spear mint, and their virtues, though similar, are greatly inferior.

The hairy water mint is supposed to be *auricularia*, *planta Zeylanica*, or earwort, celebrated by Marloe for the cure of deafness.

ME'NTHA PIPERI'TIS. PEPPER MINT. *Mentha piperita* Lin. Sp. Pl. 805; hath acuminate leaves on very short pedicles, and the flowers set in short thick spikes or heads: it is a native of this kingdom, and its natural soil is a watery one; but in any other it does not degenerate.

Pepper mint hath a more penetrating smell, with a stronger and warmer taste than the other mints. In the mouth it feels at first hot, afterwards cold, and somewhat nitrous. From its stomachic, antispasmodic, and carminative qualities, it is of great use in flatulent complaints, hysteric depressions, nausea, and other dyspeptic symptoms; often producing immediate relief by diffusing a glowing warmth through the whole system. Its qualities are with great probability ascribed to the camphor, which the experiments of Gaubius have proved to be largely contained in it, and it is seldom injurious from its stimulus.

It readily and strongly impregnates either water or spirit by infusion: in distillation with water it gives over a large quantity of essential oil, of a pale greenish yellow colour, growing darker coloured by age, and possessing a great degree of the smell and pungency of the herb. As much of this oil as can be suspended in rectified spirit of wine is sold under the name of the essence of pepper mint. The decoction which remains after distillation, like that of the other mints, is bitterish and subastringent. For the water, spirit, and oil, see MENTHA SPICATA.

ME'NTHA PULE'GIUM. See PULEGIUM.

ME'NTHA SPICA'TA; *mentha sativa* Lin. Sp. Pl. 805, *mentha vulgaris*, HART MINT, and COMMON SPEAR MINT, hath oblong, narrow pointed leaves, joined close to the stalk, and small purplish flowers,

standing on long spikes on the top. Though a native of warmer climes, it is common in our gardens, and flowers in June and July.

The smell of mint is agreeably aromatic, and the taste bitterish and moderately warm; it is carminative and stomachic, particularly useful in relieving vomitings and weakness of the stomach. An infusion of mint in water is said to prevent the coagulation of milk in stomachs where acidity prevails; and in general this herb nearly resembles the pepper mint, though perhaps less efficacious as an antispasmodic, and more injurious as a stimulant. In vomitings from inflammation in the stomach it is injurious.

The juice expressed from the leaves retains the bitterness and astringency, but not the aroma of the mint, which, however, is not lost by keeping, drying, or a moderate degree of heat. In five or six hours cold water extracts the more agreeable and active parts of the mint; a longer maceration extracts the grosser and less agreeable portions. Hot water more quickly extracts its virtues, but boiling dissipates the aroma. Infusions and tinctures contain the whole virtue of the mint; the oil and the distilled water only the aroma.

Mint water should be distilled from the fresh herb, and it is improved by adding some dried mint. In distillation with water an essential oil rises, which is of a pale yellowish colour, changing by age to a reddish hue: about an ounce is procured from ten pounds of mint, which for this purpose should be gathered when the flower is expanding. The oil is not, however, an agreeable preparation.

Dry mint yields to spirit of wine, either with or without heat, all its virtue, without its disagreeable parts. Spirit takes up very little in distillation. An extract made with spirit possesses the concentrated virtues of a large portion of dried leaves. Fifteen grains of the resinous extract obtained from either the common mint or pepper mint, by means of spirit of wine, is said to be equivalent to six drachms of the dried herb. The spirituous tincture mixes with watery liquors without precipitation; but spirituous liquors impregnated with its pure volatile parts by distillation turn milky on the admixture of water. A conserve made in the usual way is an excellent vehicle for other medicines, in diseases of the stomach.

Tincture of mint is made by adding to a pint of mint water half an ounce of the dried leaves of mint: after standing four hours in a warm place, it must be strained. The distilled water contains as much of the volatile part of the herb as it can retain; but by infusion it takes up as much of the extractive matter as pure water. Thus any of the simple distilled waters may be much improved, and, when required, the waters distilled from one vegetable may be the menstruum for a different one.

The college of physicians order from the *mentha sativa*, and *mentha piperitis*, a water and a spirit, which are directed to be made as follows. Take of spear mint or pepper mint dried, one pound and a half, water sufficient to prevent an empyreuma; and to the same quantity of the herb they order one gallon of spirit, with water sufficient to prevent an empyreuma. In each process they draw off a gallon. The essential oils of each are obtained by distillation. See OLEUM.

MENTHA'STRUM. See MENTHA AQUATICA.

ME'NTULA, (from the Hebrew term *matah*, a staff). See PENIS.

ME'NTULA ALA'TA. See PENNA.

MENTULA'GRA, (from *mentula*, and *αγρα*). A disorder of the penis, induced by a contraction of the erectores musculi.

ME'NTUM, (*ab eminendo*, from its sticking out). The CHIN is the anterior protuberance which terminates the lower part of the face; the under part of the chin is termed its basis, distinguished from the throat by a transverse fold, extending from ear to ear; in the middle of the chin a dimple is usually found.

MENYA'NTHE'S TRIFOLIA'TA, et PALU'S-TRIS. See TRIFOLIUM PALUDOSUM.

MEPHI'TIS, (from the Syriac term *mephuhith*, a blast). A POISONOUS EXHALATION, or what the miners call a DAMP. It was formerly applied to any air, not respirable, especially if attended with an offensive smell. Modern chemistry is more accurate; and what was with little discrimination called mephitic is now hydrogen, nitrogen, or carbonic acid gas.

MERCURIA'LIS, (from *mercurius*, quicksilver). MERCURIAL, or a PREPARATION OF MERCURY. But in obsolete authors, the *atra bilis* is also called the MERCURIAL HUMOUR; and the diseases from this source have the same appellation. In botany it is the name for *laphathum unctuosum folio triangulo, blithum, chenopodium, bonus Henricus* Lin. Sp. Pl. 318, ALL GOOD, ENGLISH MERCURY, a plant with triangular leaves, covered underneath with a whitish unctuous meal: its stalks are striated hollow, partly erect and partly procumbent, bearing on the tops spikes of small imperfect flowers, each of which is followed by a small black seed, inclosed in the cup; perennial, grows in waste grounds, and flowers in August. The leaves are mucilaginous, a little subsaline, and used as emollients in clysters and fomentations. The young shoots are eaten in spring as a gentle laxative and diuretic. See Raii Historia.

MERCURIA'LIS A'QUA. See BEYA.

MERCURIA'LIS FRU'CTICOSA INCA'NA TESTICULA'TA; *mariscum, thelygonon, mercurialis tomentosa* Lin. Sp. Pl. 1465. CHILDREN'S MERCURY, is a garden plant, and used in Barbary against some female diseases.

MERCURIA'LIS MAS, *mercurialis testiculata, spicata*, and *famina*. FRENCH MERCURY. It is the *mercurialis annua* Lin. Sp. Pl. 1465, var. *α.* and *β.* hath smooth glossy leaves, and branched stalks. Each variety is annual, and grows wild in shady uncultivated grounds. The leaves have no remarkable smell, and very little taste; they are slightly mucilaginous, but seldom used.

MERCURIA'LIS MUCILA'GO. See ARGENTUM VIVUM.

MERCURIA'LIS; *cynocrambe, canina brassica, persicaria siliquosa, mercurialis montana*, WILD MERCURY, DOG'S MERCURY, *mercurialis perennis* Lin. Sp. Pl. 1465, is one of the poisonous plants found in Great Britain. The root is creeping, light coloured, and fibrous; the stalk erect, green, juicy, and unbranched. The leaves are oval, serrated, pointed at the extremity, placed in pairs opposite each other. The flowers grow at the tops of the stalks in thin slender spikes from the axils of the leaves, of a light green colour, and are male and female. The furrows of the germen receive a barren

filament, terminated with a gland, marked with two dark coloured spots. It flowers early in the spring; is found in woods, shady places, and the banks of ditches; distinguished from the French mercury by being perennial, larger, with rough leaves, and the stalks not branched.

In early spring it may be eaten with safety, dressed like spinach; but its acrimony is soon evolved, and it produces nausea, vomiting, and afterwards comatose symptoms. These ill effects are removed like those of poisonous mushrooms. See AMANITA and VENUM.

Wilmer's Observations on Poisonous Vegetables.

MERCURIUS. QUICK OF LIVING SILVER; from its great fluidity. See ARGENTUM VIVUM.

MERCURIUS ALCALISATUS. ALCALISATED MERCURY; *hydrargyrus cum creta*; QUICKSILVER with CHALK; *Aethiops albus*. R. Hydrargyri puri ℥ iij. cretæ pp. ℥ v., rub them together until the globules disappear. Ph. Lond. 1788.

MERCURIUS CALCINATUS; *mercurius præcipitatus per se*. CALCINED QUICKSILVER, *hydrargyrus calcinatus*. This preparation is directed to be prepared by exposing a pound of quicksilver in a flat bottomed glass cucurbit to a heat of about 600 degrees, in a sand bath, till it becomes a red powder. By agitation, or by triture, similar effects are produced on the mercury, and in much less time. This has lately been a fashionable preparation, but is scarcely, if at all, superior to calomel, though the prejudices of the moment have occasionally given it the preference with ourselves and others.

MERCURIUS CINNABARINUS. See CINNABAR FACITIA.

MERCURIUS CORROSIVUS SUBLIMATUS. See MERCURIUS CORROSIVUS ALBUS.

MERCURIUS CORALLINUS, *arcanum corallinum*. This was designed to render the *mercurius nitratus* rubeo a more mild internal medicine; but as no considerable advantage was obtained by the process, it has been rejected.

MERCURIUS CORROSIVUS ALBUS. THE WHITE CORROSIVE MERCURY; *mercurius corrosivus sublimatus, gas siccum sublimatum, albi, aquila alba, sublimatum, hydrargyrus muriatus*, MURIATED QUICKSILVER. The modes of preparing this medicine are various; but the college of London direct quicksilver and vitriolic acid two pounds of each, dried sea salt three pounds and a half: the quicksilver is to be mixed with the acid in a glass vessel, and boiled in a sand heat till the matter is dried; which is added, when cold, to the sea salt, in a glass vessel. The whole is sublimed in a glass cucurbit, with a heat gradually raised, and the sublimed matter separated from the scoræ. Pharm. Lond. 1788.

The greatest part of this preparation used in England is brought from Holland and Venice; and, as has been suspected, adulterated with arsenic. Dr. Lewis gives the following method of detecting the fraud: "Take any quantity of the suspected white corrosive mercury, powder it in a glass mortar, and mix it well with twice its weight of black flux (see CALCINATIO,) and a little filings of iron; put the mixture into a crucible capable of holding four or five times as much; give a gradual fire until the ebullition ceases, then hastily increase it

to a white heat: if no fumes of a garlic smell be perceived during the process, and if the particles of iron retain their form, without any of them being melted, we may be sure that the mixture contains no arsenic." Neumann denies the possibility of this preparation being adulterated with arsenic, and observes, that, instead of their subliming together, the arsenic will attract the marine acid to itself, and the mercury will be revived, instead of sublimed in the form of this preparation.

Sublimated mercury is peculiarly adapted to those cases in which the slow continued action of the metal is required, particularly in eruptions, in glandular indurations, and some similar complaints. In lues it often fails, after having first appeared to succeed. It was given by Van Swieten in lues, dissolved in corn spirit; and in this form it sits most easily on the stomach; but the watery solution is not inconvenient in this respect. A small proportion of crude sal ammoniac in the solution prevents the precipitation. It may be given also in pills mixed with the crumb of bread, and the dose, at first, should not exceed one fourth of a grain. See ARGENTUM VIVUM.

MERCURIUS DULCIS SUBLIMATUS; DULCIFIED MERCURY SUBLIMATE, *calomelas*; and when the sublimation hath been ten or twelve times repeated, *panacea mercurii*.

It is the *mercurius corrosivus albus*, dulcified by the addition of crude mercury. The London college directs the proportion of nine ounces of purified quicksilver to twelve ounces of the muriated quicksilver: rub them, it is added, together till the globules disappear, and sublime; in the same manner repeat the sublimation four times; afterwards rub the matter into the finest powder, and wash it by pouring on boiling distilled water. Ph. London. 1788. In the Augustan Dispensatory one sublimation only is required. See ARGENTUM VIVUM.

The marks of sufficient dulcification are, its being perfectly insipid to the taste, and indissoluble by long boiling in water. If the water hath taken up any part of the mercury, it may be discovered by dropping into the liquor an alkaline solution, which will precipitate the mercury it may contain. If the dulcified mercury turns black on being mixed with lime water, or volatile alkali, it is duly prepared.

We have already mentioned Mr. Scheele's preparation of calomel in the humid way, and explained its principles. We shall now add the process at length, translated from the Stockholm Transactions.

"Half a pound of quicksilver and the same quantity of nitrous acid are to be put into a small vessel with a long neck, the mouth of which is to be covered with paper. The vessel is then to be placed in a warm sand bath; and after a few hours, when the acid affords no signs of its acting any longer on the quicksilver, the fire is to be increased to such a degree that the solution may nearly boil. This heat is to be continued for three or four hours, taking care to move the vessel from time to time, and at last the solution is to be suffered to boil gently for about a quarter of an hour. In the mean while we are to dissolve four ounces and a half of fine common salt in six or eight pints of water. This solution is to be poured boiling into a glass vessel, in which the above mentioned solution of quicksilver is to be mixed with it, gradually,

and in a boiling state also, taking care to keep the mixture in constant motion. When the precipitate is settled, the clear liquor is to be drained from it, after which it is to be repeatedly washed with hot water till it ceases to impart any taste to the water. The precipitate obtained by this method is to be filtered, and afterwards dried by a gentle heat. This is the hydrargyrus muriatus mitis of the London Pharmacopœia, only that they order four ounces of sea salt, instead of four ounces and a half.

"It might be supposed, that when the nitrous acid ceases to effervesce with the mercury, it is saturated with it; but this is far from being the case: the acid, when the heat is increased, being still able to dissolve a quantity of it; with this difference, however, that the quicksilver at the beginning of the process is calcined by the acid, but afterwards is dissolved by it in a metallic form. In proof of this we may observe, that not only more elastic vapour arises, but also, that by adding either fixed or volatile caustic alkali we obtain a black precipitate; whereas, when the solution contains only calcined quicksilver, the precipitate becomes yellow by such an addition. If this black precipitate is gently distilled, it rises in the form of quicksilver, leaving a yellow powder, which is in fact that part of the mercury which, in the beginning of the operation, was calcined by the nitrous acid.

"The boiling of the solution for about a quarter of an hour is necessary, in order to keep the hydrargyrus nitratus in a dissolved state, it being much disposed to crystallize. In general, some of the mercury remains undissolved; but it is always better to take too much than too little of it, because the more metallic substance the solution contains, the more hydrargyrus muriatus mitis will be obtained.

"It is necessary to pour the mercurial solution into the solution of salt by little at a time, and cautiously, so that no part of the undissolved quicksilver may pass along with it. Two ounces of common salt are sufficient to precipitate all the mercury; but then it may easily happen that some superfluous mercurius corrosivus attaches itself to this precipitate, which the water alone is incapable of separating completely. This is undoubtedly the reason why mercurius precipitatus albus is always corrosive. I have found that common salt possesses the same quantity as sal ammoniac, viz. that of dissolving a greater quantity of mercurius corrosivus. I therefore employ four ounces and a half of common salt, in order to get the mercurius corrosivus entirely separated."

Of all the preparations of mercury, calomel is the most frequently used; and all the virtues attributed to mercury this preparation apparently possesses. The dose is from gr. i. to ℥i. according to the intention; but five or eight grains are rarely exceeded.

We have said, that probably calomel might supply every other preparation; but that accident, or the routine of practice, easily becoming a habit, sometimes fixed a preference for other forms, without their possessing any real superiority. In glandular complaints calomel seems to be preferred; but small doses of the muriated mercury are often equally efficacious. In cutaneous complaints, it is often used in combination with the antimony, though from the preparation employed, the sulphur auratum, its virtues, as a mercurial, are greatly

diminished. In the early preparation of Dr. James's powder (see JAMES), calomel formed a portion; and it has been lately fashionable to add it to the antimonial, in the early periods of fevers, to secure a discharge from the bowels as soon as possible. The exhibition of calomel with camphor and opium, in the early stages of pleurisy, as recommended by Dr. Lysons, we think a more doubtful practice; and on this account we are unable to speak of its effects from experience. If, however, it is found to supersede the necessity of frequent bleeding, as has been asserted, it will undoubtedly be useful; but we do not find that the plan has been sufficiently followed to enable us to decide on its efficacy or eligibility. In the confluent small pox calomel has been given to assist or bring on the salutary salivation; but in this disease it has been dangerous from its inflammatory stimulus, nor is there sufficient time to produce the necessary evacuation. Rubbed upon the inside of the lips, it has produced similar effects to those which are occasioned by taking it internally, particularly in the lues venerea: in cases of chancres also, used by itself, or in the following form, it is highly advantageous.

R. Cerat. lapid. calamin. ℥ss. calomelanos pp. ℥i. m.
MERCURIUS DUPLICATUS PHILOSOPHICUS. See REBIS.

MERCURIUS EMETICUS FLAVUS. *Hydrargyrus vitriolatus, turpethum minerale*; VITRIOLATED MERCURY, and TURBETH MINERAL.

Take of purified quicksilver, vitriolic acid, of each a pound; mix in a glass vessel, and heat them by degrees, until they unite into a white mass, which is to be perfectly dried with a strong fire. This matter, on the affusion of a large quantity of hot distilled water, immediately becomes a yellow powder. Rub the powder carefully with this water in a glass mortar; after it has subsided, pour off the water; and, adding more distilled water several times, wash the matter till it becomes insipid. Pharm. Lond. 1788.

To edulcorate it more quickly and effectually, the water intended to be used in its abluion is impregnated with a determined proportion of fixed alkaline salt; and by this means the quantity of the preparation will be increased, and its strength more equal.

The yellow emetic mercury is a powerful vomit; and, like other mercurials, will excite salivation: in robust habits it hath been used in cutaneous disorders and glandular obstructions. As an emetic, it hath been given to eight or ten grains; but in this dose it operates violently, and is only employed when the shock of vomiting is required to be considerable. It is thus sometimes useful in palsies, and more certainly in amaurosis. Half a grain or a grain, given every night, is said to have produced the best effects in the most inveterate cases of the venereal disease, in obstinate rheumatisms, and ulcers that were difficult of cure. It is a powerful medicine, but yet does not appear to excel the other less violent mercurials, except in particular instances, where considerable and rapid effects are necessary, and where the constitution is robust. It is a favourable medicine with some active practitioners, particularly Dr. Maryatt, in dropsies. See Maryatt's Art of Healing.

MERCURIUS PRÆCIPITATUS RUBER. *Hydrargyrus nitratus ruber*. Pharm. Lond. 1788. RED PRECIPITATE. The London college directs us to take of

purified quicksilver and nitrous acid, each a pound; muriatic acid, one drachm by weight; to mix in a glass vessel, and dissolve the quicksilver in a sand bath; then to raise the fire till the matter is formed into red crystals. Pharm. Lond. 1788. As soon as it hath acquired the sparkling red colour it should be immediately removed from the fire, or it will soon lose it again.

This preparation is sometimes mixed with minium and vermilion, but then the peculiar brilliancy is destroyed. If only minium is added, it may be detected by giving a sweetish taste to vinegar. If laid also on a very hot iron, the mercury will evaporate, leaving the lead behind.

The red nitrated quicksilver is only used externally as an escharotic; and if finely powdered and mixed with the unguentum resinæ flavæ, in the proportion of one or two scruples to an ounce, it is an excellent digestive for foul ill conditioned ulcers, bringing on a proper purulent discharge, instead of a thin sanies.

UNGUENTUM HYDRARGYRI NITRATI. See TRACHOMA.

CERATUM HYDRARGYRI NITRATI. CERATE OF NITRATED QUICKSILVER. R. Unguenti hydrarg. nitrati; cerati spermatis ceti āā ℥ij. m. It is sometimes applied to scrofulous and phagedenic ulcers.

MERCURIUS PRÆCIPITATUS ALBUS. *Calx hydrargyri alba*. WHITE CALX OF QUICKSILVER. The London college directs the following process: take of muriated quicksilver, sal ammoniac, water of kali, each half a pound; dissolve first the sal ammoniac, afterwards the muriated quicksilver in distilled water, and add the water of kali; wash the precipitated powder until it becomes insipid. Ph. Lond. 1788.

Great care is required lest more of the fixed alkali be added than is necessary, for the precipitate will then be yellow. This preparation is almost constantly confined to external uses. Half a drachm or two scruples of it, added to an ounce of pomatum, is used as an elegant cure for the itch; the same quantity may be dissolved in two ounces of a thick decoction of lintseed, as a liniment for curing chancres when situated on the glans penis, or on the inside of the prepuce; a rag being dipped in it is applied to the glans, and the prepuce may be drawn over it.

This precipitate is adulterated with starch, and with white lead. The first is discovered by its becoming glutinous on being dissolved in a small quantity of water; the second by adding one third of its weight of alkaline salt; heating the mixture in a crucible till no fumes arise. If the residuum does not melt in water, it is adulterated.

MERCURIUS PRÆCIPITATUS DULCIS. Ph. Lond. 1721. See HYDRARGYRUS MURIATUS MITIS.

MERCURIUS PRÆCIPITATUS PER SE. MERCURIUS CALCINATUS.

MERCURIUS SACCHARATUS. SUGARED MERCURY. A preparation designed to give the mercury in a liquid form. Equal quantities of brown sugar candy and mercury are triturated till the globules disappear, adding a few drops of the oil of juniper.

MERCURIUS VITÆ, *angelicus, Algarothi pulvis*. THE MERCURY OF LIFE; the precipitate formed by diluting butter of antimony with water.

This powder when edulcorated is a calx of antimony, always nearly of the same strength, and therefore some-

times preferred to the glass in preparing tartarised antimony.

ME'RGEN, (from the Arabic term *morgan*). See CORALLIUM.

MERLU'CIUS, (*quasi maris lucius, the sea pike*). See ASELLUS MARINUS.

MERYOPHYLLON. See MILLEFOLIUM.

MEROCE'LE, (from *μερος, the thigh, and κλη, a rupture*). See HERNIA FEMORALIS.

ME'ROS, (from *μερω, to divide*). See FEMUR.

MESANG DE VA'CCA. See BEZOAR BOVINUS.

MESARÆ'ON, *μεσαραιον*, (from *μεσος, medius, and αραια, belly*). MESENTERIUM, q. v.

MESARAI'CA, vel MESARAI'CA MA'JOR VE'NA, (from *μεσαραιον, the mesentery*). The MESARAI'CA OR MESENTERIC VEIN, is the continuation of the vena portæ ventralis. (See PORTÆ VENA.) It bends towards the superior mesenteric artery, and accompanies it in those portions of the mesentery and mesocolon which belong to the small intestines, the cæcum and right portion of the colon; as it runs down it forms an arch obliquely, like that of the artery, which is also ramified on the convex and concave sides. It very closely accompanies the mesenteric artery, and is branched out in nearly the same manner.

MESARAI'CA MI'NOR VE'NA. See HÆMORRHOIDALIS INTERNA VENA.

MESENTE'RICÆ ARTE'RIÆ, (from *mesenterium, the mesentery*). The upper mesenteric artery, called *colica, seu mesenterica superior*, rises somewhat below the cœliac. The aorta a little above its division gives off the inferior, viz. the *colica sinistra seu mesenterica inferior*, to the left side upon the mesocolon, the lowest branch of which goes to the extremity of the anus, and forms the hæmorrhoidal artery. The upper branches anastomose with the superior mesenteric, and are azygous. The upper mesenteric branch forms a large arch in its course from the right side to the left of the mesentery; and from its convex side many branches pass to the intestines, where they communicate by reciprocal arches. A few branches go from the concave sides, spreading themselves in the mesocolon, colon, &c.

MESENTE'RICÆ GLA'NDULÆ. THE MESENTERIC GLANDS. The lymphatic glands in the mesentery are larger in young than in old subjects; and, if not the proper seat of scrofula, they are always affected in that disease.

MESENTE'RIUM, (from *μεσος, the middle, and εντερον, intestine*;) *epichordis; mesaræon*; the MESENTERY, thus named from its being in the middle of the intestines, is a duplicature of the peritonæum, nearly of a circular figure fixed in the middle of the abdomen, connected by a cellular membrane, expanding and receiving the intestines. It begins loosely upon the loins, extending to all the intestines, except the duodenum; but that part of it which belongs to the large intestines is called *mesocolon*, and is a production of the true mesentery. The diameter of this circular membrane is somewhat more than four inches, and the circumference when its plaits are unfolded are about three clls in length: the intestines plaited on this circumference are nearly three times that length. The inner membrane is most strictly its own; and in it the vessels and the glands are found. The two exterior

ones are from the peritonæum, and between these the arteries and veins lie, whose branches are dispersed on the intestines. It confines the intestines, and sustains the arteries, veins, lymphæducts, and nerves, in their passage to and from them.

Many disorders are described by different authors as arising from the mesentery; but Dr. Hunter thinks it is rarely the seat of disease; and that even its glands, sometimes disordered in children, are not affected so frequently as is suspected. Riverius, in the chapter on obstructions in the mesenteric glands, observes that the causes and cure are the same as in similar disorders of the liver. See *Praxis Medica*, lib. xiii.

MESENTERITIS, (from *mesenterium*). Dr. Cullen considers it as a species of PERITONITIS, q. v. calling it *peritonitis mesenterica*. See INFLAMMATIO MENTERII.

MESURE. A disorder of the liver, mentioned by Avicenna, accompanied with a sense of heaviness, tumour, inflammation, pungent pain, and blackness of the tongue.

MESOCO'OLON, (from *μεσος*, the middle, and *κωλον*, the colon). When the mesentery has reached the extremity of the ilium, it contracts and becomes the mesocolon. One lamina, turned to the right side, is called the right ligament of the colon. The mesocolon then rising to the right kidney, seems to be lost by the adhesion of the colon to the kidney and the first curvature of the duodenum; a circumstance which explains the utility of purgatives in nephritic cases. When it again appears, its breadth increases, and it passes under the stomach, liver, and spleen, downwards to the left kidney. The circumference, at this part, is very little plaited, and the colon is affixed to it, so as to hide the ligamentary band at its smaller curvature. By its smaller circumference it incloses the duodenum in the triangular sheath, already described, and, by its larger, the colon, forming in its passage a slight adhesion to the greater curvature of the stomach.

It contracts below the left kidney, forming the ligamentum coli sinistrum, and then expands again, fixed to the convolutions of the colon as in the superior portions. See MENTERIUM.

MESOGA'STRION, (from *μεσος*, and *γαστήρη*, the stomach,) the connecting membrane, or the concave part of the stomach, which attaches it to the adjacent parts. See OMENTUM.

MESOGLOSSI, (from *μεσος*, and *γλωσσα*, the tongue). See GENIOGLOSSI.

MESOMERIA, from *μεσος*, and *μηρος*, the thigh,) that part of the body which lies betwixt the thighs. Rufus Ephesius.

MESOMPALION, (from *μεσος*, and *ομφαλος*, navel). The middle of the navel.

MESOPHYRON, (from *μεσος*, and *οφθαλμος*, the eye,) that part of the face which lies betwixt the eyebrows. Rufus Ephesius.

MESOPLEURIOI, (from *μεσος*, and *πλευροι*, the ribs). See INTERCOSTALES.

MESORECTUM, (from *μεσος*, and *rectum*, the straight gut). It is a production of the peritonæum, which invests the intestinum rectum. About the middle of the fore side of this intestine it forms a semicircular fold, which appears when the intestine is empty, but is lost when full.

MESOTHE'NAR, (from *μεσος*, and *θενος*, the palm of the hand,) is a flat and nearly a triangular muscle, lying between the first phalanx of the thumb and the bottom of the palm of the hand, inserted into the ligament which connects the os magnum of the carpus to that which supports the thumb, as well as into that bone of the metacarpus which supports the middle finger, and to that which answers to the index: from thence, the fibres contracting to an angle form a tendon, which is inserted into the head of the first phalanx of the thumb. Winslow.

ME'SPILUS, (from *ὄμι ἐν τῷ μεσῷ πῖλος*; because it has a cap or crown in the middle). The MEDLAR. *Mespilus germanica* Lin. Sp. Pl. 684. The common medlar is about the size of an apple tree; leaves strong and sharp pointed; flowers in May, and the fruit ripens in September. In Germany these trees are wild; with us cultivated. The fruit hath an austere astringent taste, which is lost when kept so long as to appear rotten; and it is then cooling and slightly astringent.

ME'SPILUS A'piifolio. See SPINA ALBA.

METACA'RPIUS, (from *metacarpus*). A small fleshy muscle, situated obliquely between the large internal angular or transverse ligament of the carpus and the whole inside of the fourth metacarpal bone; fixed by a tendon to the os orbiculare, and to the neighbouring part of the large ligament of the carpus: at its other end to the outer edge of the fourth metacarpal bone.

METACA'RPION, **METACA'RPUS**, (from *μετα*, after, and *καρπος*, the wrist,) that part of the hand situated between the wrist and the fingers. The ancients called the carpus *brachiale*, and the metacarpus *post brachiale*. It forms on the inside the palm, and on its outside the back of the hand, but the first phalanx of the thumb is not a part of the metacarpus. The metacarpal bones support the fingers. Each bone of the metacarpus is long and flatted at the ends. The anterior surface of each body is concave, with a sharp ridge in the middle to separate the interosseous muscles. The ends next the arm have a hollow, for the articulations of the carpus; and those next the fingers are distinguished by protuberances for fixing the ligaments that unite these bones. A rough ring is observable round their heads, where the capsular ligaments that unite them to the fingers are fixed. These bones are united to the carpus and to each other by surfaces almost plain, as little motion is required; and, in those of the fœtus, each end is usually cartilaginous. The hollow of the hand is formed by the concavity of the fore part of these bones, and, from the minute motion of which they are susceptible, they form a secure basis for the action of the fingers.

METACINE'MA, (from *μετα*, and *κινειν*, to remove). A removal of the pupil of the eye from its proper situation.

METACO'NDYLI, (from *μετα*, and *κονδυλος*, a knuckle). The last joints of the fingers next the nails.

METALLA, (from the Hebrew term *metil*, a hard substance). METALS, OR METALLIC SUBSTANCES, are distinguished by their splendour, their opacity, their fusibility, specific gravity, conducting power, hardness, elasticity, malleability, ductility, tenacity, and combustibility. From their hardness and elasticity, they are

adapted for the construction of different instruments employed by surgeons; and these properties fit them for discovering solid bodies by the vibrations they convey to the hand, as a stone in the bladder, or a bullet under the muscles. Their splendour is connected with their opacity, for all metals are impervious to light; and the green rays, which seem to pass through the thinnest gold leaf, are seemingly owing to light transmitted through an accidental fracture.

All metals are fusible; and mercury even retains its fluidity in our greatest colds. The specific gravity of the lightest metal, arsenic, is more than five times greater than water, and much more considerable than the densest stone, which is not suspected to be metallic. The metals are the best conductors of electricity, and it has been supposed that the electrical fluid is conveyed through our system more readily by the small proportion of iron which the blood contains. This is, however, improbable, as the electrical shock follows more closely the course of the nerves than of the arteries.

Metallic substances are also called perfect or imperfect. The first are not permanently altered by the greatest heat of our furnaces; while the second, when exposed to a strong heat, with the access of free air, are changed by a process similar to burning, and in some instances with an actual flame, into an earthy substance called *calx*, which is heavier than the metal from which it was produced, though its specific gravity is less. This arises from the union of vital air, which converts some metals into acids. If the calx of a metal be exposed to a strong heat in a closed vessel, with some inflammable matter, styled a flux, it recovers its metallic state. This is called reduction, or reviving of the metal.

All metals are imperfect, except gold, silver, and platina. The imperfect metals are, mercury, lead, copper, iron, tin; and the semimetals, bismuth, nickel, arsenic, cobalt, zinc, antimony, manganese, molybdæna, tellurium, titanium, chromium, columbium, osmium, iridium, and uranite, with some others whose nature is not yet accurately ascertained. As the appellations arsenic, antimony, manganese, wolfram, and molybdæna, are given to the ores, the term of regulus is often employed to distinguish the metal, though modern chemists often use the terms indiscriminately.

The heaviest metal is gold, then follow platina, mercury, lead, silver, copper, iron, and tin. The most malleable also is gold, followed by silver, copper, tin, iron, lead, platina, zinc, bismuth, antimony. The force of cohesion is greatest in gold, next in iron, silver, brass, and copper, successively: tin is far below copper, and lead still less cohesive. The order of fusibility is the following, tin, bismuth, lead, zinc, antimony, silver, copper, cobalt, nickel, gold, iron, manganese, and platina. Different proportions of tin and lead are still more fusible; and, if bismuth be added, this property is increased. Five parts of tin, three of bismuth, and two of lead, become soft in boiling water. This last property renders such metallic mixtures highly useful as injections for anatomical preparations.

All the metals dissolve in acids. See AFFINITY; and in these solutions the metal is in a state of calx.—Neumann, Chaptal, Fourcroy, and Thompson's Chemistry.

METALLUR'GIA, (from *μεταλλον*, a metal, and

εργον, work). METALLURGY; the chemical doctrines of metals, particularly respecting their separation, depuration, and preparation.

METAPE'DIUM, (from *μετα*, and *πους*, the foot). See METATARSUS.

METAPHRE'NON, (from *μετα*, and *φρενες*, the diaphragm). See DORSUM.

META'STASIS, (from *μετατιθημι*, to transfer,) *diadexis*, *diadoche*, a translation of a disease from one part to another. The term is limited to a change of determination, for when matter or water passes through the cellular membrane, it is not called a metastasis.

METASY'NCRISIS, (from *μετα*, and *συγκρινω*, to mix together). The word generally implies a change in any given part. Asclepiades. See MEDICINA (History).

METATA'RSIUS, (from *μετα*, and *ταρσος*, the tarsus of the foot). A fleshy mass lying under the sole of the foot, fixed by one end to the fore part of the great tuberosity of the os calcis, and terminating in a short tendon, inserted in the tuberosity and posterior part of the lower side of the fifth bone of the metatarsus. It moves the last bone of the metatarsus, and draws the fourth bone along with it, contracting the sole of the foot.

METATA'RSUS, (from *μετα*, and *ταρσος*, the tarsus,) *planta*, *planum*, *vestigium*, *metapedium*, is composed of five bones, similar to those of the metacarpus, but, in general, thicker and stronger; their round ends not so broad, and less in proportion to their bases. Their bodies are also sharper above, and flatter on the sides, with the inferior ridge inclined more to the outside, and larger tubercles at the lower part of the round head.

ME'TELLA NUX. See NUX VOMICA.

METEORI'SMUS, (from *μελειωρος*, a vapour). See TYMPANITES.

METEOR'ROS, (from *μετα*, and *αιρω*, to elevate). Elevated, suspended, erect, sublime, tumid; pains affecting the peritonæum, or the superficial parts of the body, opposed to more deep seated ones. Galen.

METHEMERI'NOS, (from *μετα*, and *ημερα*, a day). See QUOTIDIANA FEBRIS.

METO'PIUM, an oil, or an ointment described by Dioscorides, named from the plant which produces galbanum: sometimes it means the oil of bitter almonds. See AMYGDALÆ.

METO'PON or METO'PUM, (from *μετα*, and *ωψ*, *oculus*). See FRONTIS OS.

METO'SIS. An amaurosis, from an excess of short-sightedness.

ME'TRA, (from *μητηρ*, a mother). See UTERUS.

METRE'NCHYTA, (from *μητρα*, the uterus, and *εγχυω*, to pour into). INJECTIONS for the uterus.

METRE'NCHYTES, (from the same). A WOMB SYRINGE.

METRI'TIS, (from *μητρα*, the womb). INFLAMMATIO UTERI, q. v.

METROCE'LIDES, (from *μητηρ*, a mother, and *χελις*, a mole). See NÆVUS.

METROPROPTO'SIS, (from *μητρα*, the womb, and *προσιπιω*, to fall down). See PROCIDENTIA UTERI.

METRORRHA'GIA, (from *μητρα*, the womb, and *ρηγνυμι*, to break out). See MENORRHAGIA.

ME'U, ME'UM, (from *μειον*, less,) on account of its diminutive size. SPIGEL, BAUD, or VAULD

MONEY. *Athamanta meum* Lin. Sp. Pl. 353. *Feniculum Alpinum*, is a perennial plant, whose leaves are much smaller, and seeds broader, than those of fennel. The root resembles that of fennel, but is of a more agreeable though fetid smell, and a more pungent taste.

ME'UM ALPHI'NUM GERMA'NICUM. GERMAN or MOUNTAIN SPIGNE'L, *mutellina*, *phellandrium mutellina* Lin. Sp. Pl. 366. It possesses only the virtues of the common sort.

ME'UM LATIFO'LIUM ADULTERI'NUM, *seseli perenne folio glauco breviori, faniculum sylvestre, ferula folio breviori, saxifraga montana minor*, BASTARD SPIGNE'L, *seseli montanum* Lin. Sp. Pl. 372, grows on dry hills, and flowers in June. The root is drying and pungent.

MEXICA'NUM BALS'AMUM, (from *Mexico*, of which it is a production). See PERUVIANUM BALSAMUM.

MEXICANA'VA. See BOTRYS MEXICANA.

MEZE'REUM, an indigenous appellation. See LAUREOLA FEMINA.

MIA'SMA, (from *μιασμα*, to pollute). MIASMATA have lately claimed the attention of pathologists, as they are the causes of some of the most fatal fevers to which mankind are subject. In the more strict pathological investigations of modern authors they are distinguished from contagion, which is confined to the effluvia from the human body, when subject to disease; yet this contagion, when it does not proceed immediately from the body, but has been for some time confined in clothes, is sometimes styled *miasma*. Another kind of miasma as already noticed, (see CONTAGION,) is putrid vegetable matter, and indeed every thing of this kind which appears in the form of air. Miasma, then, strictly speaking, is an ærial fluid, combined with atmospheric air, and not dangerous except the air be loaded with it; for diffusion, as we have seen, renders it harmless. It is not always discoverable by the smell, and scarcely ever by the nicest eudiometrical tests: it is not therefore hydrogen or azote, though there is great reason to suppose that it is a modification of these; for, from marshes hydrogen generally arises, and, from the human body, the chief injurious exhalation is azote. Hydrogen and azote also destroy irritability, or induce sudden debility, effects generally found from the miasmata which produce fever. As we know not the nature of miasmata, therefore, we cannot discover their corrector. Diffusion, however, renders them harmless, and it is sufficient for us that free air will prevent their deleterious effects.

What the variety of miasmata may be we cannot say. Each infectious disease has its own, diffused round the person which it has attacked, and liable to convey the disease at different distances, according to the nature of the complaint, or to the predisposition of the object exposed to it. This part of the inquiry rather belongs to contagion, and to the particular disease. A patient in the small pox seems to diffuse an infectious atmosphere to the distance of from ten to fourteen feet: measles and scarlatina are less active in this respect, and even the plague seems not to be infectious, except from fomites, but from actual contact.

The miasmata of marshes, those only whose effects we can more distinctly perceive, produce intermittents, and remittents of the worst kind. They produce also

dysentery and the epidemic catarrh, of which the infection is usually conveyed by the air. The bilious fever of America we have supposed to be the natural autumnal remittent, and therefore may be referrible to the same source; nor can we avoid concluding that every endemic disease must have its origin in the peculiar exhalations of the country.

The putrid vegetable matter which has been accused as the cause of many fevers may be truly such, for we know that many parts of vegetables produce azote. Yet their effects in this respect have not been traced with accuracy. Continued fevers are chiefly referrible to contagion: but the causes of intermittents in some constitutions seem to produce fevers of the more continued form; and the miasmata of marshes, when they have excited their peculiar fever, may certainly, through the medium of the human body, produce continued fevers. Human effluvia confined, independent of a morbid state, become undoubtedly the cause of fevers the most continued in their form, and are then truly miasmata.

MI'CA, (from *μικρος*, small). A morsel, a crumb, a grain; also a foliated semi-transparent stone, formerly, and at present in the Russian navy, used as glass. It is of the magnesian genus, but not used in medicine. See HAÛY, iii. 208. Thompson's Chemistry, iii. 462.

MI'CA THU'RIS. See OLIBANUM.

MI'CA PA'NIS, the soft part of bread; employed in preparing mild cataplasms, by soaking slices of new bread in water until they become perfectly soft, and then pressing out the superfluous water, beating the bread up with a spoon, and stirring into it a small quantity of lintseed meal. It is used also in its dry state, as a convenient mass for pills.

MI'CRO-LEU'CO-NYPHÆ'A, (from *μικρος*, small, *λευκος*, white, and *νυμφαία*, the water lily,) *nymphaea, morsus ranæ*, FROG BIT, *hydrocharis morsus ranæ* Lin. Sp. Pl. 1466, grows in muddy waters, and flowers in July. It is said to resemble in virtues the leuco-nymphæa.

MI'CRO-NYPHÆ'A, (*μικρος*, and *νυμφαία*). A variety β of, and in every respect resembling, the above. It is less than the nymphæa; grows in ditches, and is said to possess the same virtues.

MI'CROS. See DIGITUS.

MID'WIFERY. See OBSTETRICATIO.

MIGRA'NA. A corruption of HEMICRANIA. See CEPHALALGIA.

MILIA'RES GLA'NDULÆ, (from their resemblance to millet seeds). See SEBACEÆ GLANDULÆ.

MILIA'RIA, MILIA'RIS FE'BRIS, (from the pustules resembling millet seed). The MILIARY FEVER, by the Germans *Friesel*, placed by Dr. Cullen in the class *Pyrexia*, and order *Exanthemata*; defined "a synochus attended with restlessness, frequent sighing, a fetid sweat, and pricking of the skin; red, small, distinct spots, on an uncertain day of the disease, break out copiously over the whole skin, except the face, whose tops discover, after a day or two, very small white pustules, continuing but a short time." This fever is now generally supposed to be symptomatic only, because it never appears contagious or epidemic. It sometimes attends febrile affections, as well those of an inflammatory as of a putrid nature, but it seldom occurs in any, unless a hot regimen and sweat precede.

The French and German authors, however, still consider it as an idiopathic disease, and we have twice seen it when the regimen could not be accused as the cause, though it must be allowed to have been often the creature of art, since, after the disuse of the hot regimen, its appearance has been rare. When the pustules are white it is called *purpura alba*, when red, *purpura rubra*. It is almost exclusively confined to child-bed women, though it sometimes appears during the sweating regimen in rheumatism.

This disorder is denominated simple when none but *miliary* pustules accompany the red ones, which, when appearing alone, are called a *rash*. If we speak of it as an idiopathic disease, we must employ the language of those who have described it as such. They say that it is peculiar to some constitutions, who experience the disease repeatedly in their lives, and peculiarly affects the tender, the weak, and the irritable; preceded by sighing, great lowness, oppression on the præcordia, and ushered in by shivering, followed by heat and a pricking sensation of the skin; nor does the anxiety and lowness cease till the eruption is completed. Unlike other exanthemata, the eruption does not conclude the disease, for successive crops often appear, preceded and attended with the same symptoms. According to circumstances, the fever sometimes rises to phrenitis, and sometimes sinks into a typhus. The pustules, first apparently filled with serum, afterwards with a whitish fluid, at last dry, and scale off in branny crusts.

It is not, we have observed, contagious or epidemic; the eruptions have no regular periods of appearance or duration; and though the origin and source of the disease are said to be at no distant period and country, yet traces of it are discoverable even in Hippocrates. All these circumstances strongly militate against its being an idiopathic disease, and the only connection which has been discovered, if it be really a discovery, between the different states of constitution subject to miliary fever is, that it more often attends those subject to considerable hæmorrhages. Such discharges certainly occasion great irritability; and the disease is not connected with mere debility, since it is not peculiarly attendant on typhus. On the other hand, the appearance of the urine is peculiarly pale, and the smell of the perspiration is acid; but the former is an almost constant attendant on fevers in their commencement, and the latter is peculiar to the perspiration of child-bed women.

The accidental symptoms of miliaria are remission and exacerbation of the fever, but at no regular periods. The sleep is disturbed, often interrupted; tremor, subsultus, and even convulsions, come on. Occasionally, the pulse sinks, the eruptions assume a purple hue, clammy sweats and death follow. The directions for the cure of this fever have been strangely and without reason embarrassed. If it is symptomatic of a too hot regimen, we shall find little other regulation than with caution to lessen it. If idiopathic, similar plans should be followed, and according to the principles laid down in the articles DIAPHORETICA and MORBI CUTANEI, we should conduct the perspiration steadily and slowly. Cool instead of cold drinks should be employed, the cooling neutrals freely given, and the bowels kept free by the mildest laxatives. The nervous symptoms are best

relieved by camphor, which the stomach usually bears with ease, and should the strength sink, a little wine may be cautiously allowed, or ether added to the camphorated draughts. In general, however, cool free air is the greatest cordial. Even Fischer, after the experience of sixty years, advises us not to be too anxious to force on the discharge from the skin; and we have seen that cool air is the most effectual diaphoretic. See DIAPHORETICA.

When the pustules assume a purple hue, which in this country is an occurrence peculiarly rare, the bark and port wine, in quantities proportioned to the violence of the symptoms, are necessary, and when the debility is considerable, bark, independent of putrescency, has been given. This may be requisite, but we have never found it so, and there is always danger that bark may occasion a stricture on the skin and check the salutary diaphoretic. When inflammatory, phrenitic, or pneumonic symptoms come on, they must be treated according to the rules laid down under the proper heads, urging, however, the general evacuations with caution, and trusting rather to the topical ones. Blisters are never useful, except in such cases of topical congestions.

See Hoffinan and Sir David Hamilton's Treatise on the *Miliary* Fever. Sydenham *Miliaris nova Febris*, *Schedula Monitoria*; Fischer et *Febre Miliari*; Allioni de *Miliaria*. De Haen *Ratio Medendi*; Colin de *Miliaria*. Cullen's First Lines, edit. 4. vol. ii.

MILIA'RIS NAU'TICA, and PURPURA'TA, species of Typhus: the former is called by Huxham *febris nautica pestilentiâlis*.

MILIA'RIUM, (*μυλιαριον*). See ALEMBICUS.

MILIO'LUM. A small tumour in the eye lids, of the size of a millet seed.

MILITA'RIS AIZOI'DES. See ALOIDES.

MILITA'RIS HE'RBA, (from *miles*, a soldier,) from its efficacy in curing fresh wounds. See MILLEFOLIUM.

MIL'IUM, (from *mille*, a thousand, because of its numerous seeds). MILLET, *cenchrus*, *panicum Italicum* and *miliaceum*, Lin. Sp. Pl. 83 and 86, hath large, broad, grass like, somewhat hairy leaves, encompassing the stalk of three or four feet in height, bearing on the top a large pendent panicle, composed of many slender stalks, with many small glumes, including small, white, hard, shining grains. It grows plentifully in Poland; is sown in April, reaped in August or September, and is used as food. See ALIMENT.

MIL'IUM I'NDICUM, *sorgo*, *sorghum*, *melica*, *Holcus*, *Holcus sorghum* Lin. Sp. Pl. 1484. INDIAN MILLET is sown in Spain, Italy, and other warm countries. In Turkey they feed their hogs and poultry with it; but in the human body it induces constipation.

MIL'IUM ARUNDINA'CEUM, *Coix lachryma Jobi*, Lin. Sp. Pl. 1378; the *lithospermum*.

MILLEFO'LIUM, (from *mille*, a thousand, and *folium*, a leaf). *Lentibularia*; *supercilium* and *lumbus Veneris*, *myriophyllum*, *chiliosphyllum*, COMMON YARROW; MILL FOIL, *Achillea millefolium* Lin. Sp. Pl. 1267, is a plant with rough stiff leaves, divided into small segments, set in pairs, along a middle rib, like feathers; the little flowers stand thick together in the form of an umbel on the top of the stiff stalk, and consist each of several whitish or purpleish petals, set round a loose disk of the same colour, followed by small crooked seeds.

It is perennial, grows plentifully on sandy commons, and flowers almost all the summer.

The leaves and flowers are considered to be mild corroborants, and antispasmodics; their sensible qualities promise some activity, for they have a weak but agreeable aromatic smell, a slightly bitter, rough, and pungent taste: the leaves are most bitter, the flowers have most smell, and the young roots a glowing warm taste like that of *contrayerva*, but the smell is greatly diminished by drying. By the Greek physicians this plant was esteemed a vulnerary and styptic, generally employed internally as an astringent in all hæmorrhages. Stahl and Hoffman used it in bleeding from the lungs and nose, too copious flow of the menses, and bleeding piles. Stahl considered it not only as an astringent, but a powerful tonic, antispasmodic, and sedative; it is now neglected, and the leaves and flowers only are appropriated to medical purposes, if it should be employed.

Both water and spirit extract the virtue of the leaves and flowers; but water the astringency, and spirit the aroma, in the greatest degree. If the flowers are distilled with water they yield an essential oil; and if the plant is gathered from a rich soil, the oil will appear of a blue colour; if otherwise it will be green. A strong decoction of the root and leaves is said to have cured a dysentery. See Raii *Historia*; Lewis's *Materia Medica*.

MILLEFO'LIIUM AQUATICUM. See MYRIOPHYLLON.

MILLEGRA'NA MAJOR, (from *mille* and *granum*, grain). See HERNIARIA.

MILLEMO'R'BIA, (from *mille*, and *morbis*, a disease). See SCROPHULARIA MAJOR.

MILLE'PEDES, (from *mille*, and *pedes*, feet). See ASELLI.

MILPHO'SIS, (*μυλωσις*). A Greek primitive. A BALDNESS OF THE EYE BROWS: sometimes an increase of the flesh in the corner of the eyes.

MILZADE'LLA, (from *milza*, Span. *the spleen*, from its virtues in diseases of the spleen). See LAMIUM MACULATUM.

MIMO'SA NILO'TICA, seu ÆGYPTIACA. See ACACIA.

MIMO'SA JAPONICA CA'TECHU. See TERRA JAPONICA.

MIN'E'A. See ANIME.

MINERA'LIA, (from *mina*, a mine of metals).

MINERALS. The mineral kingdom furnishes numerous and very valuable remedies, first introduced by the chemical physicians, and, for a long time disregarded by the Boerhaavian school. They were supposed by the latter to be unalterable in the stomach by the digestive powers, and consequently incapable of producing any change in the circulating fluids, the source, in their opinion, of all diseases. Dr. Cullen first clearly pointed out, that many medicines, particularly opium and arsenic, produced considerable changes, though thrown up with an apparently undiminished bulk, and that therefore they acted on the stomach as a nervous organ, sympathetically connected with the rest of the system. Since that time, the opinions of the chemical sect have been revived with more distinct and more rational views, and copper, arsenic, barytes, with some other medicines of considerable power, introduced into the *materia medica*. In the views of the natural historian the study of mineralogy has been attended with greater difficulty.

In the system of Linnæus, who was very imperfectly acquainted with minerals, the form alone was considered as the basis of the classification; and forms, at that time little known, or described with no very discriminated minuteness, led rather to confusion, than distinction. Cronstedt first conducted his arrangement with scientific accuracy, but his system was chemical, and the general rules, as well as the conduct of the historians of the other kingdoms of nature, rested their discriminations on external forms. Daubenton, the friend and coadjutor of Buffon, suggested an union of these two plans, but the revolution was completed by Werner and Haüy within a very few years.

It is unnecessary to mention a great variety of systematic arrangements. That of Cronstedt was comprised in four great divisions; earths, salts, inflammables, and metals, to which he has added, in an appendix, compound and conglomerated stones, petrifications, and volcanic productions. He has been followed, with no change in the great outlines, by Mr. Kirwan. While the chemical mineralogists were thus meliorating their system at their furnaces or their lamps, a considerable revolution was preparing in Germany and France. In the school of Freyberg, where the subject, from the neighbouring mines, forced itself on the attention of naturalists, Werner laboured at rendering the descriptive language more copious, more expressive, and more accurate. To every appearance of shade, colour, hardness, taste, smell, &c. he gave appropriate appellations, often with a disgusting harshness which obscured what he attempted to explain, but with the most minute and accurate discrimination. Haüy, in France, was at the same time observing with minuteness the form of the crystals, and investigating by the most patient research, aided by the most accurate geometrical constructions, the original molecule, on which the future more compound crystal is moulded. In this enquiry he had an assistant in Romé de l'Isle, but his last most valuable work is wholly his own. That of Romé de l'Isle was published near twenty years since. Haüy, however, though he rests greatly on the form of the crystals, neither neglects the chemical analysis, nor the strict language of Werner; and the general merit of his work has led us to prefer it as the most convenient book of reference, to ascertain the species intended, especially as his copious list of synonyms lead us equally to the best authors of the chemical and the Wernerian schools.

Haüy's first class contains the COMPOUNDED ACIDS, viz. those substances in which the acid is united to an earth, an alkali, and occasionally to both. The second comprises the PURE EARTHS, except where they may be united with an alkali. The third contains the COMBUSTIBLES, and the fourth the METALS. The appendix is filled with those bodies whose nature is unknown, compound, and volcanic substances.

Werner, though he has so carefully improved the language of mineralogy, yet rests on chemical analysis as his chief support. The principal divisions of former authors it is impossible to overlook or neglect, for they are strongly pointed out by nature; and EARTHS, SALTS, COMBUSTIBLES, and METALS, are also his classes. He has added the classification of rocks, which he divides into primitive, transitive, alluvial, and volcanic. His object in this arrangement will be sufficiently obvious

from the titles. Of Werner's system we have no very satisfactory account in our own language. His work on the "External Character of Fossils" has been translated, but the language is disgusting and rugged. M. Brochant's two volumes of mineralogy, in French, give a much more favourable view of his doctrines; and this work is more valuable, as it goes hand in hand with that of Haüy, a circumstance which enhances the value of each. Mr. Jamieson's description of the minerals of Scotland, and a few others from the school of Freyberg, are calculated rather to disgust than allure the student.

Werner has improved the science in one respect, viz. in preserving the natural families, which, like the natural orders in botany, connect kindred substances. Haüy has been equally successful in connecting these kindred tribes from the form of their crystals; and so just is his method, that the arrangement which these first suggested afterwards received their best support from chemical analysis. Another improvement of Werner is the arrangement of subjects, not from the predominance of their component parts, but from the character. Many reputed argillaceous earths have often the largest proportion of silex, but they are arranged with propriety as clays. This, though sometimes attended to, was not before the era of the Freyberg professor strictly kept in view, and it has greatly improved his system as a natural one; the first and great object in every department of natural history.

The chief difficulty in mineralogy is the means of ascertaining species; and, when we proceed to other subjects which have been supposed less susceptible of the advantages of arrangement, we shall find the difficulty less considerable. Every author depends on the chemical nature of the object for the establishment of species; and Werner expressly observes, that bodies, which differ essentially in their chemical nature, differ also as species. The error lies in not affixing an accurate idea to the word "*essentially*," for Werner often depends on differences purely accidental; and the establishment of sub species in almost every modern system shows the uncertainty of the foundation of specific differences. Haüy has formed his species on the chemical nature of substances, but he has added essential external characters, very striking and discriminated. Brochant has done the same, but not always with equal success.

It is a singular remark of prince Gallitzin in his "Alphabetical Collection of Mineralogical Names," that the possible combinations of the nine principal earths, excluding the saline and metallic *mixtures*, exceed forty thousand, of which we have yet discovered scarcely more than fifty. How inexhaustible are Nature's stores, and what resources may not medicine and the arts have still in reserve? The siliceous earths form nearly one half of the known combinations, the calcareous only furnish five, and the aluminous seven.

We have perhaps been led too far from our medical department; but this subject has not sufficiently shared the attention of the English naturalists or physicians. We shall now return to our proper path, and endeavour to point out the comparative advantages of each class, in a medical view.

EARTHS. The first of these in the modern systems is the *barytes*, and we employ only the muriated salt, though a solution of the pure or aerated barytes has

been recommended vaguely, as an anthelmintic, and, externally, as a destroyer of the life of a part. The purer or carbonated *lime stones* are absorbents, and, by this quality, they appear to act as astringents. From a loose analogy, they have been supposed useful in other excessive evacuations, where their power will not extend. The more incapable they are of absorbing acid, the less effectual they appear, unless when joined with some acids, they act according to common opinion as astringents in the intestinal canal. Their lithontriptic power has been sufficiently explained.

MAGNESIA is highly useful as an absorbent, and, when joined with acids, as a laxative: the *clays* we have found demulcent, and, from this effect, apparently astringent. The *flints* including the gems, though formerly celebrated, are now deservedly forgotten; nor, excepting the portion suspected by Dr. Gibbes in the Bath waters, is there any known form in which siliceous earth is swallowed, or in which it can be useful.

The **STRONTIA** has been recommended as a diuretic, and an astringent, but we cannot ascertain the authority. It is probably an absorbent.

The **SALTS** are more frequently advantageous, and, in their different forms, are useful laxatives, refrigerants, absorbents, and tonics. The two former objects are obtained by the neutrals; the two latter by the alkalis and acids. The volatile alkali is conspicuous as a stimulant, the vegetable acid as a refrigerant. Alum seems the chief objection to the general remark, though it appears to act occasionally as a laxative.

The **INFLAMMABLES** offer very few medicines, and with the exception of sulphur, and perhaps the petroleum, none of importance. The ambergris, and the asphaltum, are now deservedly neglected. The succinum used only for its salt and oil.

The **METALS** furnish the most numerous and the most valuable medicines, which we need not enumerate, as, with the exception of lead only, they are chiefly tonics; and, when we particularly examine its properties, we shall find them in some views according with those of the other metallic bodies. The metallic salts are often externally corrosive.

If then we find, in the inexhaustible variety of possible combinations, that we have yet discovered few, so in those which we *have* discovered, a very small proportion are useful as medicines; and when, from the whole of the mineral kingdom, with all the various preparations, we have selected twenty important ones, we need scarcely regret the loss of the rest. It must be recollected that the fifty known combinations from the forty thousand, are combinations of earths only; and that the combinations of the metals only with the acids would furnish as many more, of which a very small proportion has been actually discovered.

Kirwan's Mineralogy; Haüy *Traité de Mineralogie*; Mineralogie de Brochant; Wallerii *Systema Mineralogicum*.

MI'NIUM, (from *samminia*, a Chaldee word). See **PLUMBUM**.

MI'NIUM GRÆCO'RUM and **PU'RUM**. See **CINNABARIS**.

MINU'TA, (from *minuo*, to diminish). An epithet for a violent fever, with such great debility as to be fatal in four days.

MIRA'BILIS, (from *miror*, to wonder,) a term

applied to various compositions, expressive of their admirable virtues.

MIRA'BILIS A'QUA. See PIPER JAMAICENSE.

MIRA'BILIS PERUVIA'NA. See JALAPA.

M'RI. See CEBIPIRA BRASILIENSIBUS.

MISERE'RE ME'I, a name applied to the iliac passion, from the severity of the pain. See ILIACA PASSIO.

MISTU'RA, (from *misceo*, to mix). A MIXTURE, in the strictness of pharmaceutical language, differs from juleps in not being transparent, in consequence of some powder or extract dissolved or mixed with it. See JELAPIUM.

MISY. We should not have retained this obsolete word, had we not seen it styled a sulphat of iron. It is synonymous with the calcantha or calcanthum of the ancients, q. v. and in reality a sulphat of copper. Haüy, iii. 586.

MITE'LLA, (quasi *mitrula*, dim. of *mitra*, a band). A scarf for suspending the arm. In BOTANY it is the name of some plants from America and the north of Asia, comprehended by Linnæus under the genera *mitella* and *tiarella*.

MITHRIDATUM, (from *Mithridates*). See CONFECTION DAMOCRATIS, and MEDICINA (history).

MITRA'NIS VA'LVULA, (from *mitra*, a mitre, from their resemblance). See COR.

MIVA CYDONI'ORUM, (from the Hebrew term *migma*). MARMELADE of QUINCES. See CYDONIA.

MIXTIO, (from *misceo*, to mix). MIXTION. Stahl used this expression to signify the union of the first principles in the most simple compounds. Those principles of bodies are now emphatically called a *mixt*, which are so intimately united to each other as to be scarcely discovered, though without changing the nature of either, and without any union by chemical affinity. A mixt is thus distinguished from aggregates, where the texture is loose, and the parts more easily separated. In chemical mixtures the nature of the ingredients is altered, and a new body formed.

MO'CHLIA, (from *μοχλος*, a lever). A reduction of the bones from an unnatural to a natural situation.

MO'CHLICA, (from *μοχλευω*, to move). Violent purges.

MODE'RN, (quasi *hodierni*, of to-day). The æra of modern learning, according to the best chronologists, is that of the capture of Constantinople by the Turks, when the Greeks fled to Italy, carrying with them their literary treasures. This was on the 27th of May 1453. This æra will not, however, be accurate in the history of medicine, for in tracing the progress of our science we have seen it gradually progressive from east to west, and sometimes even in a contrary direction; and were we to fix the limits with respect to medicine, we should place them at the decline of the Grecian physic, in the court of Byzantium, and the last of the ancients would be Actuarii. The comparative knowledge and skill of the ancients and moderns have occasioned great controversy. It is pleasantly, though not with great impartiality, treated by Swift in his *Battle of the Books*. Duten's work "On the Discourses of the Ancients attributed to the Moderns," contains many curious and important facts on this subject; but this author, like some others, catches too anxiously at casual hints, and expressions, seeming to mistake a lucky but a loose con-

jecture for a discovery. Pancirollus, in his work *De Rebus Perditis et Inventis*, and Bæckmann, in his *History of Inventions*, offer many curious facts respecting the science of the ancients, and often respecting medical opinions and the use of remedies. Two volumes have been added by the latter author to those already translated, which would be a valuable acquisition to the English reader.

MODI'OLUS, (from *modus*, a measure,) since it is contrived to enter only to a certain depth. The crown or saw of the trepan; or a circular trepan resembling in shape the nave of a wheel, which is its true signification. See TREPHINE.

MODIO'LUS, (femin. of *modus*), the axis of the cochlea of the ear.

MODI'RA. See COLUBRINUM.

MOFFA'T WATERS. A mineral spring near Moffat in Scotland, resembling the Harrowgate waters; equally sulphureous and saline, but not equally bitter. They have been chiefly used in scrofulous and cutaneous disorders, and more lately applied to irritable ill conditioned ulcers. Their contents are chiefly sea salt and hepatic air; but the former is in so small a dose as scarcely to act as a laxative. In indigestion from weakness, in calculous cases, and in biliary obstructions, they have been employed, but are not sufficiently powerful in their action on the bowels for the latter complaint. They chiefly act as diuretics.

MOGILA'LIA, (from *μογίς*, difficulty, and *λαλέω*, to speak). A difficulty of speech; *psellismus acheilos* of Dr. Cullen. See ANCYLOGLOSSUM.

MO'KEL. See BDELLIUM.

MO'LA, (a Hebrew term). A name for the *patella*, KNEE PAN, for the *molars dentes*, or grinders; for the *maxilla*; and a FALSE CONCEPTION, or a shapeless mass in the uterus, without a placenta, called *epicyema*, *myle*, and by Avicenna, *naducem*. Should part of the placenta remain in the uterus after the birth of the child, this may resemble a mole; and it is then called *pseudo-mola*, a FALSE MOLE. If the symptoms of a miscarriage happen in the first, or beginning of the second month, the fœtus being then very tender, and lying in the os internum two or three days, will dissolve, it is said, into a kind of jelly, which, coming away, is called a *false conception*; and if, during the time of child-bearing, a flooding occurs, a large coagulum of blood, with a fibrous appearance, is discharged some time after its cessation: this also is called a *mole*. It differs from the placenta in being only fibrous on the outside.

We cannot indeed deny, that the tender fœtus may melt into a jelly, or that coagula may become fibrous, but the appearances of *molæ* seem to be owing to a more recondite origin. It is ridiculous to talk at this time of a plastic power, or a tendency to organization; yet either imperfect rudiments of a fœtus pre-exist in ovaria, or by some unknown process there is an approach to organization. We have numerous records of the remains of hair and teeth in ovaria of women of character, and in circumstances where there can be no deception. We have similar appearances in the brute creation. We find, too, that, when married women have been in a bad state of health, which has prevented conception, an organized mass is often discharged on their recovery before a living fœtus is produced. We have much reason to suspect, then, that in every instance

moles are imperfectly organized productions, and that they may be both formed and discharged in some instances without any blemish on the female character, whatever theory may be adopted respecting their origin. In many instances what is styled a *mole* is merely a coagulum of blood.

The signs of a mole are, in general, the same as pregnancy. It is said, indeed, that in the former case the belly increases more rapidly than in pregnancy, and after the third month it generally produces floodings. Women of experience, however, always feel some variety in their symptoms and sensations, and generally suppose they are not with child.

A mole is also distinguished from pregnancy by its exciting no motions in the womb like those of a living child, and by changing its situation in the belly according to the posture of the mother. The general health is commonly worse, after the fourth month while in pregnancy it improves.

Should the existence of a mole be ascertained, assistance is necessary, the finger may be gradually introduced into the uterus, and its action excited by a slight irritation. As there is no placenta, so, if after the discharge of the mole the flooding ceases, the whole is at an end, except another may remain, a circumstance peculiarly rare, which however will soon follow. See La Motte, Smellie, and Hamilton.

MOLA'GO CO'DI. See PIPER NIGRUM.

MOLA'RES DE'NTES, (from *mola*, a mill, and *dens*, a tooth). GRINDERS, *genuini*; *gomphioi*; *molæ*; *momisci*; the large broad teeth beyond the canini.

The two first are smaller than the rest, terminating in two points, and therefore styled by J. Hunter *bicuspides*. They have short fangs, which are double at their extremities. The other three on each side have four points at the basis of their bodies, two anteriorly, and two posteriorly; these have generally two fangs in the lower jaw, and three in the upper. Mr. John Hunter observes, that the first and second of the grinders are nearly alike: they stand next behind the canini or eye teeth; and the first is frequently the smallest, with rather the longest fang, sometimes with its point bent. In the upper jaw, the *bicuspides* are rather thicker than in the lower; and both, especially the second in both jaws, are oftener wanting than any others, except the *dentes sapientiæ*. The *bicuspides* and the *molares* alter very little in shape on their grinding surfaces, by use; their points only wear and become obtuse. The two first grinders differ from the *bicuspides* in being much longer, and in having more points and more fangs. The body forms almost a square, with rounded angles. The grinding surface has commonly five protuberances, two of which are on the inner, and three on the outer edge or part of the tooth, with generally some smaller points at the roots of these longer protuberances. The body towards its neck divides into two flat fangs, one forward, the other backward, which are often bifurcated. The first grinder is somewhat larger and stronger than the second; and both have shorter fangs than the *bicuspides*. In the upper jaw they have three fangs; and the first and second in the upper jaw are placed directly under the maxillary sinus. The third grinder is the *dens sapientiæ*. See DENS. J. Hunter's Natural History of the Human Teeth.

MOLA'RES GLA'NDULÆ, are two glands, nearly

of the same kind with the sublingual glands, each of them situated between the masseter and buccinator muscle, resembling, in some subjects, two small lumps of fat. They send out small ducts, which perforating the buccinator, open into the cavity of the mouth, almost opposite to the last *dentes molares*; from which circumstance, Heister gave them their name.

MOLDA'VICA MELISSA. TURKEY BAUM. See MELISSA TURCICA.

MOLE. See TALPA.

MOLL. See LENTISCUS.

MOLLITIES o'SSIUM (from *mollis*, soft). A SOFTNESS of the BONES, *malacosteon*. The principal cause is a defect of bony matter, and often occasioned by a general weakness, scorbutic, venereal, or other taint in the blood. Cleanliness, a change of air, frictions, a good diet, cold bathing, exercise, and chalybeate medicines, are the proper remedies, though when the cause is known, it should be previously corrected. See MORBI SOLIDI SIMPLICIS. DISTORTIO SPINÆ. GUMMA.

MOLLIFICA'TIO, (from *mollis*, soft, and *fiō*, to make). A barbarous term for a partial palsy of the muscles.

MOLLU'GO, (from its softness). See RUBIA SYLVATICA LEVIS, and ALYSSUM.

MOLU'CCA MELI'SSA. MOLUCCA BAUM. Its qualities agree with those of melissa.

MOLUS'CUM, the appellation given by Dr. Willan to a cutaneous disease, consisting in small soft wens, which may be extirpated, but not easily resolved.

MOLLU'SCA, (from *mollis*, soft). Natural history has, within these few years, greatly extended its boundaries by new discoveries. Philosophers wanted new worlds as a supply for their ambition, new territories for their conquest, and they have discovered them by improving their instruments, by their more extensive and more acute observation. New planets, new metals, and new animals are daily attracting our attention, and, in the present department of science, they have neglected the gaudy shell, the former object of inquiry, and the subject of classification, to ascertain the nature of the animal which inhabits it. This part of the inquiry has been chiefly cultivated by the French naturalists, and the reader will obtain the most satisfactory information from these and the Linnæan Transactions. We must add, however, with regret, that the volumes, which relate to the mollusca by the successor of Denys Montfort, are inferior to many of the others, and the plan of that naturalist is not completed. In this place we can only skim over the surface, in order to apply it to medicine. We have already noticed the great outline drawn by La Marck and Cuvier, who divide animals into those which have articulated vertebræ, and those which want them. We say *articulated vertebræ*, because some of the animals before us have a bony support, particularly the cuttle fish. When vertebræ are no longer found, the blood is no longer red. All these animals were divided into insects and worms, or, as they are now called, molluscæ; but later authors have added and detracted a little from the classes of their predecessors. Bruguiere added the echinoderms, viz. the star fish and the urchins. La Marck reduced the six classes of Bruguiere to four, molluscæ, worms, radiarii (echinoderms) and the polypi, including the infusory animals. Denys Montfort,

whose work, as the chief systematic one, we must follow, divides the molluscæ into ten classes, the *M. coriaceæ* (cuttle fish); *tentaculatæ* (snails); *ejaculatores* (many of the bivalves); *annulatæ* (worms); *gelatinosæ* (medusas or blubbers); *loricatæ* (asterias); *hydræ* (multivalves); *polyphi* (madrepores); *cornææ* (lithophytes); *infusoriæ* (microscopic animals). In this arrangement, the insects, the crustaceæ, and arachnoides, are excluded; for the molluscæ undergo no metamorphosis, do not change their skins, and have no really articulated limbs.

The coriaceæ once furnished their shells as absorbent medicines. They sunk into dentrifices, and are now disregarded. One species, the sepia octopus, the octopus vulgaris of La Marck is said by Ætius, and many of the other Greek physicians, as well as the poets, to be aphrodisiac. The sepia moschata (octopus moschatus of La Marck) was esteemed for the same qualities, also as an emmenagogue, and as highly nutrient. All the polyphi are occasionally eaten. They are a hard indigestible food, employed only from necessity, and rendered as palatable as possible by the arts of cookery. The tongue is said to be delicious, and is greedily devoured raw. The animal styled the *argonaut* is of this genus; and the nautili which agree in structure with it, though not like the former, are solitary animals, also eaten by the common people.

With these animals the work of Denys Montfort concludes, and his successor is peculiarly short, imperfect, and unsatisfactory. The tentaculatæ furnish animals highly nutritive, and employed on this account in hectic. The gluten of the large black snail is said to be useful as a discutient. The only other divisions which offer medicinal substances is the seventh, which contains the sponge, and the ninth, the lithophytes, which furnish the coralline.

Histoire Naturelle de Buffon Ed. Sonnini. *Molusca*. Memoires et l'Histoire de la Societe d'Histoire Naturelle, a Paris, Annales du Musæum National. Linnæan Transactions.

MO'LVA, (from *mollis*, soft). See *ASELLUS MAJOR*.

MO'LY, (from *μολος*, battle; supposed to have sprung from blood spilt in battle). *Allium latifolium liliiflorum*. Moly of THEOPHRASTUS, or HOMER. Various plants have had this appellation, and each is a kind of garlic, though it has been styled with less reason, a species of rue.

MO'LY, ALP'NUM. See *OPHIOSCHORDON*.

MOLYBDÆ'NA, (from *μολυβδος*, lead; *elerena*, galena). *Molybdène sulphure*, Haüy, iv. 289, a metallic ore, often confounded, from its resemblance, with plumbago, but differing essentially from it. It is one of those metals which, when calcined, are acid. Its texture is lamellated, the marks it leaves of a greenish colour, and its specific gravity nearly 6, while the carbure of iron is compact, leaving black marks on paper, and in gravity exceeding 6. See also *CHEMISTRY*.

MOLY'BDAS. Molybdat. Salt formed by the union of the molybdic acid and different bases.

MOLY'BDOS, from *μολυβδος*: ὅτι μολει εἰς βάθος, from its gravity. See *PLUMBUM*.

MOLY'ZA, (a dim. of *μολυ*, moly). See *ALLIUM*.

MO'MIN. See *MAMEI*.

MOMI'SCUS, (from *μωμος*, a blemish). The part

of the dentes molares next the gums, usually covered with a tartarous matter. The molares themselves have the same appellation.

MOMO'RDICA, (*mordeo*, to bite,) from its sharp taste, *balsamina mas*, *frum Hierasolymitanum*, *frum mirabile*, *balla*, *muccapira*, *cucumis*, *momordica balsamina* Lin. Sp. Pl. 1433; the MALE BALSAM APPLE, is cultivated in gardens, but not used in medicine, though the fruit is cooling.

MOMO'RDICA ELATE'RIMUM. See *CUCUMIS AGRE'STIS*.

MONADE'LPHIA, (from *μονος*, unicus, and *αδελφος*, frater). The sixteenth class of the Linnæan system, comprehending those plants which produce hermaphrodite flowers, with one collection of united stamina. It is a natural association.

MONA'NDRIA, (from *μονος*, unicus, and *αἴηρ*, maritus). The first of Linnæus's classes, comprehending plants which produce hermaphrodite flowers with a single stamen.

MONA'NGIA, (from *μονος*, and *αγγος*, a vessel). Plants which have their seeds in a single cell.

MONA'RDA PURPU'REA; *m. fistulosa* Lin. Sp. Pl. 32. The smell is fragrant; the taste aromatic and bitterish. It has been styled a deobstruent and a stomachic; but has been chiefly employed in intermit-tents.

MONE'RES, (from *μονος*, alone,) properly a boat with a single oar; but figuratively applied to a melancholy person fond of solitude.

MONO'CEROS, (from *μονος*, unicus, and *κερας*, cornu, horn). See *UNICORNU*.

MONO'COLON. See *CÆCUM INTESTINUM*.

MONO'COLUS, or MONOPHTHA'LMUS, (from *μονος*, or *οφθαλμος*, an eye). A roller of ten or twelve feet in length, and two or three fingers in breadth, to retain the dressings on the eyes. It is fixed on the occiput, letting about a foot hang down, and from thence carried obliquely round the head, across the wound, to its commencement: having carried it thrice round, the remainder goes circularly about the temples, occiput, and forehead; the end hanging behind is then to be brought over the vertex to the forehead, and the whole secured. A napkin, or a handkerchief, is equally useful. It also signifies, as the name implies, a person with only one eye, or with one eye less than the other. See *MONOPIA*.

MONŒ'CIA, (from *μονος*, and *οικος*, domus). The name of the twenty-first class in the Linnæan system, comprehending the androgynous plants, or such as produce male and female flowers on the same individual without hermaphrodites.

MONOGA'MIA, (from *μονος*, and *γαμος*, marriage). Plants whose flowers are single.

MONOGY'NIA, (from *μονος*, and *γυνη*, mulier). The name of the first order in the first thirteen classes of the Linnæan system, comprehending such plants as have one pistil or one stigma.

MONO'MACHON. See *CÆCUM INTESTINUM*.

MONOPE'GIA, (from *μονος*, and *πηγυμι*, to compress). A pain in the head affecting only one point.

MONOPE'TALI, (from *μονος*, and *πτεταλος*, a petal). Containing but one petal.

MONOPHY'LLON, (from *μονος*, and *φυλλος*, a leaf,) *smilax unifolia humillima*, *unifolium*, *lilium con-*

vallium minus, ofhrys monophyllos Lin. Sp. Pl. 1442, ONE BLADE; grows in woods and thickets, and flowers in May and June. The flowers are styled alexipharmac and vulnerary. See Raii Historia.

MONO'PHIA, and MONO'POS, (from *μονος, solus*, and *ὤψ an eye*,) *Monoculi* and *arimaspes*, a term of the same signification in the Scythian language, from their custom in shooting, to shut one eye. In consequence of this habit the other was rarely seen, and they were said to have but one; but the same term is applied to those who have one eye less than the other. When this deformity is observed in infancy, such exercises as require the use of only one eye, as looking through microscopes, telescopes, &c. should be avoided.

MONO'RCHIS, from *μονος*, and *ὄρχις, a testicle*.

MONOSPE'RMUS, from *μονος, single*, and *σπέρμα, seed*.

MONS VE'NERIS. The HILL OR MOUNT OF VENUS, lies before and on the upper part of the symphysis of the ossa pubis, formed by fat in the subjacent cellular membrane, and in adults generally covered with hair.

MO'NSTRUM, and MONSTRO'SITAS, (from *monstro, to show*). MONSTER, or a monstrous, i. e. a preternatural production.

A monster is very judiciously defined by Dr. Hamilton, in his valuable and comprehensive Outlines, to consist in "any considerable deviation in the structure of the fœtus from the common order of nature, whether such deviation be consistent with life or not."

Monsters, according to the same author, are, 1st, those which are double, or have supernumerary parts; 2dly, those who have a deficiency of some organ; 3dly, those who have any remarkable deviation either in the situation of the viscera, the distribution of the vessels, nerves, or secretory organs, though not externally visible, or materially affecting the different functions; 4thly, the productions of animals of different species.

Monsters double, or with supernumerary organs, have been often described. The Bohemian sisters, united by the glutæi muscles, with a more intimate connection in the abdominal viscera, are well known to physiologists. The monster, mentioned in the Philosophical Transactions (No. 2), consisted of two bodies equally distinct, and in various other parts of this collection there are cases where the union is more or less complete. This double form gradually sinks to the child growing from the side of another, recorded in the Asiatic Transactions, down to the double head of the Hindoo child, in Mr. Hunter's collection. Supernumerary organs are very frequent, and this peculiarity is at times confined to particular families. It is remarkable that the peculiarity will disappear for one, and sometimes two, generations, reviving again in the third. The internal organs are occasionally double or supernumerary. The most singular case of this kind is where two hearts were discovered.

Deficiencies are also numerous. A head, an eye, an arm, a leg, a hand, foot, or finger, are sometimes wanting; but the chief deficiency, which calls for our attention is that of the head. This has occasioned many speculations; but in every instance there is a point at which all the nerves converge, or from which they proceed, and this contains very generally a cortical, or a nucleus of cineritious matter. We may, however, remark as

a fact of future application, that the acephalous children are often plump, and of no diminutive size; yet the instance has escaped us, if any has occurred, where such children are not in other respects monstrous. The vital organs must be always, to a certain degree, perfect: at least neither the heart nor the large vessels can be wanting in a child which has arrived at its full time.

The third instance of monstrosity is rare, or at least rarely ascertained. We have instances on record of the viscera being on the sides opposite to those in which they are usually placed, and the pulmonary vessels are occasionally defective, or useless from the fœtal passages continuing open. From the last cause chiefly arises the cærulian complexion of some children. Various are the changes which may occasionally take place in the distribution of the vessels, the situation of the glands, or the direction of the nerves within the limits of health; and numerous must necessarily be the instances in which these irregularities have not been observed. The imperfection of natural passages is scarcely sufficient to arrange such persons under the rank of monsters. It is a disease of structure, which merits no such appellation, and we have anxiously excluded them by our definition.

The productions of animals of different species are rare; and these very seldom, if ever, fertile. Providence has thus wisely preserved every species distinct, and the world is not peopled with monsters. Yet, among animals of the larger size, which usually produce only a single offspring, twins are rarely, both, perfect. This, however, is not the case in man, or in the lower orders of animals. We only see it distinctly in the cow.

In the vegetable kingdom, we find monsters produced by excess of nourishment, or by the opposite extreme of confinement and deficient nutriment. To the former we attribute the double unfertile flowers; to the latter the variegated leaves of plants. We are not without similar instances in the human species. The full plethoric female is seldom a mother of many children, and the Laplander, the Esquimaux, and the Cretin are deformed in their bodies, and imperfect in their intellectual faculties. They have not, however, been distinguished by the appellation of monsters.

To what are these deviations from the common structure owing? We have endeavoured to render the pre-existence of the germ in the female constitution probable; and the monstrosities observable in succeeding generations are owing probably to the imperfect germ. Where, however, parts are double, or the deviations from the common structure are considerable, we cannot admit this source. M. Lemery long since contended that monsters were rendered such by accidents in the uterus. Winslow supported the idea of Duverney, who supposed the germ to have been monstrous, and first started this opinion. Each opinion has been supported with great obstinacy by their respective authors, in the Memoires de l'Academie des Sciences, An. 1728, 1740, 1742, and 1743.

The double children are certainly such as from contiguity have accreted in their tenderest state. We can have no doubt of this in the instances recorded in the Philosophical Transactions, where they ate and slept at different hours; where their excretions and tempers were distinct and discriminated. If it be the case in these instances, may we not suppose that, by a stricter

approximation, some of the abdominal viscera may be so closely pressed as to destroy the parietes on the weaker side, and the canals to be consequently common? This was the case with the Bohemian sisters. Again, may not a more partial and a stronger pressure obliterate even the lower extremities of the weaker child, and the trunk inosculate with that of the stronger, as in the case recorded by Dr. Bland in the Philosophical Transactions? and may not a similar cause, in twins greatly disproportioned in strength, account for all the varieties of a child growing out of the side, down to the double head of the Hindoo, or even the double heart? It was not from accident that we said disproportioned strength; for the double portion is usually small and imperfect.

It is not possible to follow all the varieties. While we have admitted, at one extreme, the monstrous germ, we have endeavoured to support, at the opposite, the effects of pressure. We can go no farther. Where the limits of either cause may be, is uncertain; nor is it necessary to follow doubtful and unsteady lights in a track which leads to no useful purpose. One thing we may add, that in no instance is it probable that deficient or redundant monsters are owing to the fright of the mother, or disgusting objects presented to her.

The absurdities that crowd the pages of Schenkus, Bartholine, Ælian, De Reies, Vanderwiël, Paulini, &c. down to our own rabbit woman, and Roederer's relation of a female that brought forth a fish, must not detain us. It is enough to have stated the several facts, and to have made some approaches towards an explanation.

MO'NTA PA'NNA. See PALMA JAPONICA.

MORBI ORGA'NICI. Parts affecting the organization, sometimes synonymous with the locales. See LOCALES.

MORBI'LLI, (a dim. of *morbis*, disease). The MEASLES. *Variola cholericæ* of Avicenna; *blaciæ* of Rhazes; *bothor*; *bovilla*; *fersæ* of the Arabians. Dr. Cullen places this disease under the title *rubeola*, in the class *pyrexia*, and order *exanthemata*, defining it a contagious fever of the inflammatory kind, attended with sneezing, watery eye, and a dry hoarse cough; on the fourth day, or a little later, small spots, crowded together, scarcely prominent, break out, converted after three days into small furfureous scales. He distinguishes two species. 1. *Rubeola vulgaris*, with eruptions very small, confluent, and corymbose, hardly rising above the skin. Of this there are two varieties; in one the symptoms are more severe, and the course of the disease not so regular—the anomalous measles of Sydenham: in the other they are accompanied with a sore throat. 2. *Rubeola variolaris*, where the eruptions are distinct and elevated. Dr. Cullen, however, doubts whether this disease be truly measles; for the eruptions differ, and the catarrhal symptoms are absent: in Scotland this disease is called the *nirles*. The measles appeared in Europe nearly with the small pox: both came from the east, both are infectious, and attack only

once; both appear at a definite period after the attack of the fever.

The measles is an acute disorder, of the peripneumonic kind, sometimes only an eruptive catarrhal fever. Dr. Morton calls the scarlet fever the confluent measles; and Dr. Watson observes, that in the small pox the eruption is critical, but that in the measles it is merely symptomatic, for the cough and peripneumony are not relieved by it. It was formerly a common opinion that the measles are a good preparative for the small pox; but in general the former leaves an inflammatory tendency, which greatly exasperates the symptoms of the latter. All ages are subject to this disease, but it chiefly attacks children.

The measles usually announce their approach by a small, frequent, and dry cough, which often continues many days, without any other sensible complaint, though more frequently the cough is attended with a general uneasiness, successions of shivering and heat, and a severe headach in grown persons; great depression of the strength, a heaviness of the head in children, giddiness, hoarseness, pain across the forehead, an inflammation, with a considerable heat in the eyes, a swelling in the eye lids, a defluxion of sharp tears, and such increased sensibility that the eyes cannot bear the light, very frequent sneezing, and a discharge of acrid serum from the nose. Fever and a cough soon come on, with frequent vomiting, pain in the loins, a soreness or roughness in the throat, and sometimes a looseness, which relieves the vomiting. The tongue is furred, the urine high-coloured, and the pulse very quick, often irregular. These symptoms usually increase from the third to the fifth day, at which time little red spots, like fleabites, begin to appear in the forehead, and other parts of the face, which, increasing in number and diameter, run together, forming large red spots of irregular figures, scarcely, if at all, rising above the surface of the skin. These eruptions are afterwards extended to the rest of the body; but sometimes red effusions are seen on the breast, before any appear on the face. The eruption is not followed by so sensible an abatement of the symptoms as in the small pox; the vomiting usually abates, but the cough, fever, and headach, grow more violent: the difficulty of breathing, the weakness of, and defluxion on, the eyes, the swelling of the face, drowsiness and loss of appetite, continue, though the vomiting abates. A bilious vomiting a day or two after the eruption is often useful, and occasionally the patient is relieved by a copious discharge of blood from the nose. On the third or fourth day after the eruptions first appear the redness diminishes, the spots fall off in branny scales, while in other parts of the body they appear very large and red; but in a day or two they all disappear in the same branny scales, leaving a little discoloration on the skin, with considerable itching. On the ninth day from the beginning, when the progress has been speedy, and on the eleventh, when it hath been slow, no trace of redness remains. As the spots disappear, the defluxion on the eyes, the fever, and difficulty of breathing, sometimes increase, the cough becomes more troublesome; and these symptoms are increased by a hot regimen. These peripneumonic symptoms are often followed by a looseness, which immediately succeeds the disease, and often continues with obstinacy

after all other symptoms are removed. After a hot regimen the eruptions sometimes turn black; but this chiefly occurs in grown persons, and is often fatal. If, during the course of the disease, or immediately after it, some considerable evacuation, such as the vomiting of a bilious matter, a bilious diarrhœa, a considerable discharge of urine, or plentiful sweating come on, the patient recovers soon after the spots disappear from the skin.

The measles are sometimes followed by boils resembling anthraxes, livid, often deep, suppurating with difficulty and pain; sometimes attended by soft pustules containing a viscid straw coloured fluid, which appear highly salutary, by watery vesicles, and occasionally by aphthæ. Swellings of the lymphatic glands often follow, occasionally suppurating, and leaving, as usual, troublesome sores, which heal with difficulty.

Measles is generally a disease of little importance; but it becomes dangerous when the peripneumonic symptoms are violent, and when the eruption recedes. The most favourable symptoms, as in other fevers, are the moistness of the skin, and the bowels moderately relaxed. If the cough is inconsiderable, the eyes not much swollen, the breathing moderately free, there is little danger; but the period of difficulty is often when the eruptions begin naturally to recede. The peripneumonic symptoms are then usually violent; and if at any time the eruptions should suddenly disappear, delirium, anxiety, great debility, with cold extremities and livid spots, come on, terminating soon in death. If the lungs are affected with tubercles, they are often excited to action by this disease, and the foundation of a phthisis is laid.

The treatment of measles has, we think, been mistaken and misrepresented. It has been considered as a peripneumonic disease, and the most liberal bleedings have been ordered: but the peripneumony only comes on by accident, or by mismanagement; for the disease is purely catarrhal. The common measles rarely require *bleeding*; and, in general, the treatment is the combined management of a catarrhal and an eruptive disease. An emetic is undoubtedly at first required, and the mild relaxing diaphoretics, with neutral salts, continued through the whole course, will carry the disease safely to a conclusion. The only remedies necessary, independent of these, are *laxatives*; which, if steadily persisted in from the beginning, will very certainly prevent the occurrence of those violent peripneumonic symptoms, which sometimes come on about the eighth or ninth day. In general it is sufficient to procure two or three stools daily; but the author of this article, when his son, whose tenderness, joined with apprehension of weak lungs, rendered the measles a dangerous disease, was affected, carried the evacuations farther. He watched him hourly, and found him always relieved by stools, so that about the disappearance of the spots, six or eight motions were procured daily. He thought that the recovery was peculiarly quick: the boy was soon brought into the air, and in three days from that period not a cough was heard. No other medicine was administered, except once a slight opiate when the cough was peculiarly troublesome. He mentions the single fact, but without advising an imitation, except where the attendance can be equally unremitted.

The usual remedies of saline diuretics, with antimonials, and occasionally opiates, spermaceti, &c. must also be given, if the practitioner would not be thought ignorant or inattentive; but the laxatives should never be omitted. Should, notwithstanding the evacuations, the peripneumonic symptoms come on, bleeding will be necessary, in very young children by means of leeches; but after the age of five or six, by the lancet, with blisters, and the other remedies of pneumonia. No such instance has, however, occurred to us in an extensive practice; nor to those from whom we learned it, whose practice, equally long, had been more extensive. We have mentioned a diarrhœa as a favourable symptom, and we may now add, that it should not be checked, but regulated according to the strength. The catarrhal inflammation may rise to suffocation; and in that case the emetics must be repeated, and blisters applied to the neck or the upper part of the sternum. A blister to the pit of the stomach is generally an useless application.

When the cold regimen was introduced for the small pox, some rash innovators transferred the analogy to measles, often inducing the violent peripneumony they intended to avoid. Yet a very warm regimen is injurious; for we have shown that it is inconsistent with the diapnoe, which in every febrile disease is so peculiarly salutary. The room should be large and airy, the child kept in an erect or a slightly reclining posture, according as either can be borne from the load of the head. The drinks should not be hot, but warm only, and the food light, diluent, and in a liquid form. If the cough is troublesome, breathing the steams of warm water will be useful, but these steams should not be drawn hot from an inhaler. The warm water should be put in a bason, and the head covered with a flannel large enough to hang over its edges. The eyes will in this way be also relieved by the relaxing vapour.

Should, from debility or cold, the spots recede, convulsions, pneumonia, and sometimes phrenitis, will come on. In such cases, blisters, with warm cordials, and the warm bath, will be necessary; but this occurrence is peculiarly rare.

The continuance of diarrhœa, after the disease, is sometimes troublesome; and the sagacity of Sydenham has been highly extolled, who recommended bleeding "because the halitus of the inflamed blood was carried to the intestines." We have never found the purging troublesome when the bowels have been kept free during the disease; and when it has occurred, bleeding seems to have exhausted the little strength that remained, often without relieving the diarrhœa. In this case a generous, but not a highly stimulating, diet, bathing the feet, and giving small doses of Dover's powder, have succeeded, interposing occasionally gentle laxatives.

The *rubeola sine catarrho*, in Dr. Willan's opinion, is not true measles, nor does this disease emancipate the patient from being afterwards affected with the real complaint. Indeed the very vague distinctions of rashes will not enable us always to discriminate from the eruption alone, and to this, with the catarrh, we would add some affection of the eyes before we pronounced a child safe. The morbillous fever without the eruption is only a violent catarrh, and equally liable to deceive. The *NIRLES*, as we have said, is equally a distinct disorder from rubeola.

Dark livid spots are sometimes intermixed with the true eruptions, and in this case an alarm has been spread of putrid measles; but these little petechiæ are usually attended with no danger, and a light infusion of bark, with the vitriolic acid, soon restores the colour. Real putrid measles have been described, but Dr. Willan has shown very clearly that in each instance the disease has really been scarlatina. We cannot deny the existence of putrid measles, since we have frequently seen putrid peripneumony. The plan of treatment, however, should it occur, will be nearly the same; but we cannot enlarge on a disease which no one seems to have seen, and which may never occur.

It has been proposed to inoculate measles like small pox, and the blood, the acrid serum from the eyes, and the matter from miliary vesicles, sometimes interspersed between the true morbillous eruption, have been employed. Each has succeeded, but more often failed; nor does the disease, when produced, appear more mild. The attempt, therefore, has not been frequently made, and to avoid a complaint usually so mild, such precautions are not necessary.

See Hoffman and Sydenham, on the *Measles*; Home's Medical Facts; Tissot's Advice to the People; London Medical Observations and Inquiries, vol. iv. p. 132—135, and p. 247—260; Medical Museum, vol. ii. p. 46—48; Cullen's First Lines, edit. 4. vol. ii. p. 173; Edinburgh Medical Essays, vol. iv. art. 2; London Medical Observations, vol. iv. art. 11; Willan on Cutaneous Diseases, part i. order 111.

MORBILLOSA, belonging to the measles.

MORBUS, (from *μωρος*, death). A DISEASE; *malum, nosos*. A disease we have already defined to be "that condition of the human body in which the actions of life and health are not performed, or performed imperfectly." (See CAUSÆ.) The various imperfections in the functions therefore constitute it, a circumstance which the accurate distinction of diseases, according to nosologists, renders indispensable.

Diseases may therefore be as different as the functions injured, but this would render them too numerous, and it has consequently been usual in the morbi universales to combine a certain number of the injured functions to constitute one disease. In the local diseases, one injured function has been supposed alone to constitute a genus. Diseases, however, differ, either as many persons are usually affected at the same time, and they are then styled EPIDEMIC; or, as peculiar to one country, and called ENDEMIC: when they occur accidentally, they are styled SPORADIC. They differ also as the mind or body is affected; as any particular organ suffers; or from the cause which has produced them: but such varieties are now disregarded; and those who pursue distinctions for the sake of diagnosis, at this time, arrange diseases from their symptoms. See NOSOLOGIA.

While we omit many useless disquisitions respecting disease in its abstract, we have referred to this article for the more general pathological inquiries, and shall proceed to consider the MORBI FLUIDORUM; SOLIDI SIMPLICIS; SOLIDI VITALIS; and MORBI SOLIDORUM CONTINENTIIUM, in their order.

MORBI FLUIDORUM. We begin with diseases of the fluids, as in this form our nutriment is taken in, and, if these are defective, the whole system will suffer; though we shall soon endeavour to establish this

axiom, that the state of the fluids, in the body, depends on that of the solids, particularly the vital solid. We have already had occasion to observe, that every deviation from the sound state is not disease, but that there are different degrees of such deviations within the limits of health, though probably each may be supposed to form a predisposition to disease.

Diseased fluids are said to differ from those in the natural state, from a difference in their cohesion, or from any acrimony, formed either by the animal process, or introduced with the air or aliment. The cohesion of the fluids may be too great, constituting tenacity and lentor; or too little, when they are said to be in a dissolved state. The blood, to which these diseases are chiefly confined, we have found consisting of different parts in a state of mixture only, and the lentor can be owing only to a diminution of the proportion of water, or a less proportion of neutral salts, by which some of the gluten is kept in solution. It may be doubted whether the excess of the fibrin or gluten may not produce a similar effect, but this we shall soon consider.

The causes of lentor, which result from a diminution of the watery portion of the blood, are said to be a deficiency of drink, an increase of the fluid secretions, a stagnation and absorption of the watery parts separated from the crassamentum. Each of these causes, however, is imaginary, so far as regards this change, for the secretions are so nicely balanced, that an increase of one is followed by a diminution of the other; and when fluids are not thrown in, they are, in a great degree, checked. Thus, a nurse who has not drank any thing for a long time, is not greatly loaded with milk, but immediately, on drinking, it flows freely. The circulation also keeps up the union between the discordant portions of which the blood consists; and while the secretions are supported, no stagnation of watery fluid can take place.

The idea of Gaubius, that a glutinous matter, arising from foods of this kind which absorb water, from a weaker digestion, a more languid circulation, or insufficient exercise, is certainly imaginary; for the glutinous foods produce no such effect, and the other causes of this supposed gluten rather contribute to lessen the tenacity of the fluids. The earthy substances and their various sources, supposed to have the same effect, rest on a foundation equally insecure. The opinion has not a single fact for its support. We know indeed but one cause of lentor, high health, with a consequent increase in the proportion of the gluten and fibrin of the blood; but this is connected with increased tone, and more powerful action of the arterial system, which prevents any bad effects, but which itself constitutes predisposition to disease, under the appellation of *diathesis phlogistica*. See INFLAMMATIO.

Increased tenacity in the secreted fluids is more common; but we chiefly perceive it in the bile and the mucous follicles. It never appears to arise from any defect in the blood, but from stagnation in consequence of debility, sometimes in consequence of a want of irritability in the excretory ducts. We certainly see, in the urinary organs, that the state of the fluids, from which the urine is secreted, influences the nature of this discharge, and a suspicion may arise that a similar effect may produce morbid bile, but in neither case is

the morbid fluid referrible to lensor; and the idea of earth joined with acid, so as to form a "pitchy acrimony," is neither supported by observation nor chemical experiment.

Too great *fluidity* is in part owing to an excess of watery fluids, and such a change undoubtedly takes place; but the causes usually assigned are often imaginary. Too large a proportion of watery fluids is corrected by the increase of the watery secretions, and increased evacuations from some glands are generally compensated by the retention of other secretions. In this view an indolent life and a humid atmosphere produce certainly some effect; but the principal diseases which they previously induce are general debility and impaired digestive powers: from hence proceeds the deficiency of the gluten and fibrin; and, of course, the greater tenuity of the serosity.

A more certain cause of preternatural tenuity is acrimony. It may certainly be of various kinds, but we can only perceive with clearness the saline acrimony. Yet we have little doubt of this effect being produced by many other substances. In putrid diseases, Deyeux and Parmentier did not discover an increased proportion of ammonia; but the union of the albumen with the serum was affected, and the crassamentum (see BLOOD) was weak. Symptoms also of a preternatural tenuity of the blood come on often suddenly, without any evident cause. We dare not then carry the axiom before mentioned to its utmost extent, for causes not yet within the reach of our knowledge, often produce unexpected changes.

A peculiar tenuity of the secreted fluids often occurs, and it may arise from tenuity of the blood, increased, and sometimes inflammatory, action of the secreting vessels. Thus the increased flow of urine arises not only from an abundant proportion of water in the blood, but from the increased action of the vessels, as in hysteria, and sometimes from fright. Increased discharge of bile arises chiefly from increased action, which sometimes is occasioned by mental affections, as a violent fit of anger. In hot weather it appears owing to the increase of that portion of the circulating fluid, whatever it may be, which contributes to its secretion. The tenuity of the semen arises also from increased action, owing to the indulgence of lascivious thoughts, or improper indulgencies; of tears and saliva from the same cause, owing often to association. When the increased tenuity is owing to *inflammatory action*, the secreted fluid is usually acrid, as the tears in measles, the mucus of the nostrils and bronchial glands in coryza and catarrh, the bile in cholera, the urine in nephritis, though in the last instance the increased discharge covers the acrimony.

Morbid acrimony of the fluids has been accused as the cause of many diseases; but in the circulating system there are few marks of its existence. When separated by the powers of nature, and carried to the excretories, we perceive only its effects.

Philosophy has divided acrids into mechanical and chemical. Pathology followed, and the mechanical pathologists and therapeutists spoke with much feeling of the wounds which the tender nervous fibrils sustained by cruel angles of salts, or the salutary momentum with which mercury removed obstructions. Even the later disciples of the Boerhaavian school have disused this language, and speak of acrids as chemical only.

Nature has, however, anxiously guarded against the admission of morbid acrimony. The taste discovers, the stomach and the bowels reject, what is highly injurious. What may be less so is often altered by digestion, and the mixture of the fluids which it meets with in that process. If, however, it prevails to any considerable degree, we have reason to think that the lacteals refuse their office. When conveyed to the thoracic duct, it is slowly added to the mass, and largely diluted by the considerable proportion of the circulating fluids, and probably sheathed by the albuminous portion of the blood. But even when admitted, either by its chemical affinity or its specific stimulus, (see SECRETION,) it is carried to its appropriate gland, and by that outlet safely, often silently, carried away.

The source of morbid acrimony may be therefore air, meat, drink, condiments, medicines, or poisons; and the air may convey either miasmata or contagion. When we mention condiments, however, as a source of acrimony, we must except common salt. This seems a necessary stimulus to the process of digestion, and probably accompanies, in a small proportion, the chyle, since its acid is found in the ammoniacal salts of the blood, while its alkali appears to have undergone some change by the animal process, and to have become ammonia. We find miasmata and contagion conveyed by the air, in cases of remittents and intermittents; but a more decided acrimony is evident in the causes and consequences of epidemic catarrh and dysentery; of many of the exanthemata, and of some of the phlegmasiæ. In diseases of the skin there is also evidently an acrimonious substance eliminated, for the reasons assigned under that article. See CUTANEI MORBI. In syphilis, in hydrophobia, and many others, it is equally conspicuous.

The animal process, that is, the changes which take place in the system by the exercise of the animal functions, produces an acrimony which is usually covered by the bland nutriment, constantly supplied till carried off by the fluids, styled, for this reason, *excrementitious*. If, however, these are retained, or the supply of nourishment withheld, an acrimonious state of the fluids follows. What this acrimony is we do not clearly perceive. It is partly saline, partly, perhaps, the dissipation of, or change in, the albuminous portion of the blood, and very probably some admixture of putrid fluid. When this animal process goes on more rapidly, as in fevers, these changes are more conspicuous. The most evident consequences are, all the symptoms of putrefaction, with gangrene, putrid evacuations, fetid breath, &c.: convulsions and spasms, attributed to this acrimony, appear to come on in consequence of the debility which every degree of putrefaction induces.

The various foods which have been accused as producing acrimony in the *prima via*, and afterwards in the fluids, have probably, for the reasons assigned, little influence in this respect. The acid in the stomach produced by the continued use of acids and acescents certainly injures the digestion, and produces in consequence debility; but there is no trace of acid in the blood, none in the secreted fluids, if we except the ureal and arthritic concretions; and of these the latter only can be very obscurely traced to acescent aliment. An alkaliescent diet is uncommon. Putrid meat, or rather meat advancing to putrefaction, does not appear

injurious, if it neither excites sickness nor uneasiness in the bowels; and though dyspeptic symptoms have been observed after a continued course of alkaline medicines in cases of calculus, no injury seems to have been felt in any other organ. The tetradynamia have been styled *alkalescent plants*; and these have been blamed for introducing saline acrimony, but, on the contrary, they are the best remedies for a disease in which this acrimony very evidently exists, the sea scurvy.

The scurvy is admitted to arise from salt provisions, but in these the milder animal fluids are separated and in part decomposed; the texture of the animal fibre is also destroyed, and in reality the disease arises from a want of the supply of that bland aliment which corrects the acrimony formed by the animal process. We have evidence of the same cause producing a similar state, where unalimentary food has been for a long time taken, though without salt. It has occurred, however, only in damp, confined situations, and each cause seems to have concurred in producing debility and destroying irritability. It may be said that if this were true, bland mild nourishment should be its most effectual cure: but nourishment of this kind is not sufficiently stimulant to excite the torpid fibres; and while the state of the fluids requires acids and ascents, perhaps oxygen, the stomach is best excited by the warmer vegetables. See SCORBUTUS. Other acrimonies have not been distinctly pointed out. Effects similar to those of scurvy were found by Dr. Stark to arise from a diet on sugar: but he had before tried so many experiments, that his constitution was exhausted. A saccharine acrimony, if it may be called so, is conspicuous in the diabetes mellitus. We have seen a sweet secretion of a similar nature in the mouth, and have reason to suspect that the discharge in lientery is of the same kind. See LIENTERIA.

One other source of acrimony remains, viz. the *aromatics*. They are much insisted on by pathologists, but we have found little foundation for accusing them. We have suspected their noxious influence in those diseases of the bladder which in old age are connected with a tenderness at its neck, or some affection of the prostate gland; but it is a suspicion which rests on a slender basis. Since, however, in such cases they are not necessary as medicines, they may perhaps be more safely avoided.

The subtlety of modern investigators has, however, added to this subject a source of humoral diseases, not suspected in the schools of the mechanical physicians, and which has not yet received a public share of the pathologist's attention; we mean those changes which depend on the composition of the animal fluids. We may repeat shortly, that the carbone and the oxygen of vegetable bodies are converted by the animal process into nitrogen and hydrogen; but they still, in a certain degree exist, and the change of the oxygen gradually going on has been supposed the cause of animal heat. It is at least certain that a large proportion of oxygen is connected with a fresh florid colour of the blood, with increased vigour and activity of the circulating system, probably with an increased firmness of the simple solid. When therefore in excess, it constitutes a morbid state: such is the extreme of vigour, which, when the balance of the circulation is destroyed, favours topical congestions.

On the contrary, oxygen is too copiously expended in

different circumstances, so that its defect is equally morbid. It is too copiously separated in the active exertions of body and mind; but the former, if in the open air, greedily attracts the necessary supply both from the atmosphere and the food for which, by exercise, a craving desire is excited. In low, damp situations, and in a confined air, it is not supplied. If the food is unalimentary, the expenditure will exceed the supply; if the bodily exertions are slight, and the mental ones considerable, the excess of expenditure will be more obvious in the symptoms. These are, languid circulation, a pale cadaverous look, diminished irritability, and impaired vigour. In such circumstances the oxygen does not always appear deficient in quantity, but is not evolved in the due proportion, since it probably produces its effects in the period of its separation. Thus oxygenated remedies are not useful in the proportion of their quantity of oxygen, but in that of its loose adherence. The oxygenated muriats are by this means more beneficial than the mineral acids; and of these the nitrous is, from the same cause, superior to the muriatic, and the latter to the vitriolic, acid. An argument we think equally decisive may be drawn from the effects of light. This principle certainly separates oxygen from those bodies which contain it; but dark apartments show in their inhabitants a deficiency of this principle. In fact, it is apparently present, but too closely united to show its peculiar effects.

With the excess and deficiency of oxygen are connected the opposite proportions of azote, or nitrogen. They seem in the human body antagonising principles; but though they form air by an union not perhaps properly chemical, we cannot trace the effects of such an union, for the halitus of the insensible perspiration, if not azote, is carbonic acid gas. With hydrogen, however, the oxygen forms water; and when the oxygen disappears we sometimes see, or suspect we see, watery effusions.

We can scarcely ever discover the consequences of an excess of hydrogen or carbone. The singular stories of the spontaneous combustion of the whole body may appear to be of this kind, and to support the delusion, we are told that the victims have been persons accustomed to excesses of drinking spirits; but from such casual facts no general conclusion can be drawn. We may, with equal truth, attribute the pimples of the drunkard's face to the brandy which he has swallowed, producing an halitus of hydrogen, instead of carbonic acid gas, or azote, while they probably arise only from continued and excessive stimulus.

We have found in the blood traces of sulphur, though we are unable to discover its source. We see its excess or its separation in cancerous sores, and some malignant ulcers, which, we are told by Dr. Crawford, discharge an hepatised ammonia. The source of this sulphur, and its deposition, seems subjects equally intricate. Is this (according to modern chemists) the most truly elementary body, really a composition? Is azote a component part? or what are the consequences of an union of azote and hydrogen? "Doceat Dies!"

An excess or defect in the quantity of the fluids is scarcely an object of this part of our work, yet to consider the doctrine of plethora in this place may facilitate some future enquiries. These sources of disease are the *πολυχυμία* and *ολιγοχυμία* of pathologists, and are, on

the whole, the distinguishing marks of youth and old age. Each, as may be supposed, is relative to different temperaments, and even idiosyncracies; each may be apparently in excess, and each may predispose to disease, though still within the limits of health. The consequences of the excess of either of the component parts of the blood may be easily understood from the former observations on lentor or tenuity. We now mean to speak only of the excess of the whole mass, which is styled *plethora*. This is divided into the *plethora ad molem*; *plethora ad spatium*; *plethora ad volumen*, and *plethora ad vires*; nor is the distinction frivolous: it were better that it had been more attended to by modern authors.

The *plethora ad molem*, *ad vasa*, or *ad venas*, for they are synonymous in ancient authors, is the exuberance of the absolute quantity of blood, and, in more delicate habits, is seen by the fulness and redness of the minute vessels. In scrophulous habits, however, this redness does not always denote plethora; nor do they easily bear large evacuations, much less astringents, which are often ignorantly prescribed on account of a fancied weakness. In more robust habits this kind of plethora is chiefly discovered by a full, oppressed, or rather a laboured pulse, and sometimes by a fulness of the veins. In general it occurs in strong robust constitutions, where the digestive powers are vigorous, and the waste from exercise disproportioned to the supply.

The *plethora ad spatium* is produced when the quantity of circulating fluids remaining the same, the capacity of the vessels is contracted. This happens in cold weather, and in the cold fits of fevers, when in weak habits hæmorrhages are not uncommon. It happens also more frequently than is suspected, by the rash imprudent use of astringents, particularly in full mobile habits, in persons of a languid circulation, or in cases of hæmoptoe.

Plethora ad volumen usually implies an increased bulk of the blood from external heat, from violent inflammatory fevers, from friction, from violent passions, spirituous liquors, &c. The blood, however, is not capable of any very considerable expansion, and these appearances of plethora arise from relaxation in consequence of external warmth, or a determination to the surface, from a more accelerated circulation.

The *plethora ad vires*, though it exist, is still less an object of our present consideration, as it means only a greater quantity of blood than the strength will bear. This, of course, must be relative to the constitution of the patient; but we may add, that it is a more frequent source of disease than is suspected, and peculiarly difficult to relieve, as we have often had occasion to remark, since the slightest diminution of the circulating fluids produces faintness.

It will be obvious that these different plethoras are not inconsistent with each other, and that all may be occasionally combined. The disease such an union may produce will be of course more dangerous, and sudden death has often been the consequence.

The deficiency of blood the *ολιγοχρυσια*, is supposed to arise from copious evacuations, or from famine. Faintness, however, arises in the former instance before a considerable portion can be lost, and in the latter the contraction of the vessels accommodates them to the quantity. In the infant, however, who dies from not

tying the umbilical cord, we have remarked (see *MEDICINA FORENSIS*) that the vessels are unusually empty, and Licoutaud, as well as Morgagni, has recorded instances of the vessels being peculiarly empty, though without connecting this appearance with the previous symptoms; an omission too common in each. It is sufficient therefore to point out the existence of such a state, since from want of such information we cannot enlarge on its source or its consequences.

MORBI SOLIDI SIMPLICIS. This subject fills a large space in the foreign systems of pathology, and were it not from respect to the talents of men like Boerhaave, Gaubius, De Haen, and Ludwig, we should pass it over very slightly. It will not, however, detain us long, though we shall add in part to their views.

The diseases which can affect the simple solid are those which relate to its cohesion or its chemical nature. The state of cohesion, the only objects of the Boerhaavian school, must be relative in different organs, in different ages, sexes, temperaments, and constitutions. In general, the cohesion of the various organs must be in the natural proportion of each. If too slight to bear the requisite motions, it constitutes disease; or indeed if it require very peculiar caution to avoid injury from such motions, it is equally a disease, though in a less degree.

Weakness, or diminished cohesion, in a solid when not ruptured, is divided into, 1st, the *lax* and *flaccid* in soft parts which admit of distention by a moderate force; 2dly, the *inert*, or *inelastic*, in parts naturally elastic; 3dly, the *flexible*, as in bones which admit of being bent, after being previously softened.

When rupture has taken place in the tender fibres of soft parts, it is styled *tenerum gracile*: when accompanied with general softness, as from putrefaction, *tabidum*. It is called *fissile* when parts, naturally soft, are dry and chapped; and *fragile* when hard parts are broken in consequence of their weakness.

Rigidity, an opposite disease, consists in increased cohesion, and is styled *tenax* when in soft parts, as the muscles of old animals; *durum*, when in the harder parts, as cartilages proceeding to ossification; and *fragile vitreum* when in the bones.

In all these cases the vital solid is often the chief and the principal cause. The want of elasticity arises from water being poured into the cellular membrane instead of the usual halitus; the flaccidity and flexibility from previous debility. It is extremely doubtful whether the tender fibres of soft parts can be even broken, independent of previous disease, except in consequence of extreme violence, which is not our object; and the *fragile vitreum* attributed to cold has certainly no foundation, for the heat in the internal parts is uniform, and cold could not produce the effect without the previous destruction of life from its sedative power. If softness exist independent of these previous diseases, it must be attributed to the larger proportion of water, or a change in the chemical combination. A similar chemical change must take place in cases of rigidity, but with a diminished proportion of water. We shall therefore consider softness and rigidity as diseases independent of the distinctions just noticed.

When softness becomes a disease, the increased proportion of water, as we have said, arises often from

debility a disease of the vital solid. With respect to the chemical change, the chief substance which attracts our attention in the composition of the soft parts is the GELATIN, q. v. We must add, however, to the remarks contained in this article, some later discoveries. The gelatine then differs from vegetable jellies, in consequence of the union with lymph, an animalized fluid, containing or consisting of nitrogen. This lymph is more copious in advanced life, and in the same proportion the animal gelatine is less soluble in water. In the earlier periods of existence this gelatine admits of the union with water, but not of the later; so that softness is the disease of the young, and rigidity of the old. But we find, from Parmentier and Deyeux, that diseases chiefly affect the gelatinous parts of the blood; so that this gelatine, in early life, from its affinity with water, and in the later period if not supplied in due proportion, or with the requisite qualities, produces the diseases of the simple solid referrible to diminished cohesion. In each view, therefore, these diseases arise from an excess of water, or rather from debility; and from opposite states, rigidity, the disease of old age, must be understood. In the latter state, also, many of the smaller vessels are obliterated; the coats of the larger, which remain, are more dense, and less irritable; the exhalations fewer: changes which contribute to increased rigidity.

The fleshy parts of animals experience the progressive changes chiefly from the gradual addition of lymph in a large proportion, of which the fibres seem to consist, as they are not very soluble in water, and appear to yield nitrogen copiously; for though Thouvenel obtained what he styled extractive matter from flesh, muscles probably differ from harder parts chiefly in consequence of their containing the blood. This animalized lymph is apparently that portion of the blood which separates in the fibrin. The cartilages are chiefly gelatinous.

Bones are only subject to softness and friability, which must in this case be distinguished from fragility, as it chiefly arises from an absorption of the bony matter. Bones are originally gelatinous; and in this jelly a calcareous phosphat gradually crystallizes in different forms, according to the shape of the bone. (See BONES). The gelatinous part assumes the form of membranes by the pressure of the bony fibres, and may be seen when the earthy salt is separated by solution in acids. The bones of the fœtus are naturally soft and flexible. They continue so in a certain degree till their shape is gradually formed by the action of the muscles. The degree of softness unsuitable to the age is what constitutes disease. It arises from weakness, as in rickets, and from diseased fluids, as in scurvy, and occasionally in syphilis; and immediately depends, in a great measure, on a defective supply of the earthy salt. In rickets, debility of the digestive organs precedes the softness of the bones, and in scurvy the whole system is weakened. In syphilis the bones are perhaps eroded, and become friable rather than softened. They are, however, sometimes softened in cases of general debility, without any peculiar affection of the digestive organs, frequently from a sedentary life, and from confinement by a long chronic disease. This softness, which generally produces deformity, and in one instance rendered the pelvis so deformed as to require embryulcia, or the Cæsarian section in a woman who had before born

children of the usual size, does not produce the peculiar appearance of rickets, because it happens when the shape of the bones has been more perfectly established, as we shall see in that article.

Since, however, our attention has been more particularly turned to the changes in the lymph, we may be allowed to doubt whether the softness of young bones, or the friability of old ones, is wholly owing to the change in the bony matter. Each may be affected by a change in the state of the lymph, as already explained, and in part to the greater or less extent of the vascular system: to these views we may return under RACHITIS, q. v.

MORBI SOLIDI VIVI. The solidum vivum, in the language of Gaubius, is the living portion of our bodies, or, in other words, the nervous system, in which we include, with Dr. Cullen, the brain, the spinal marrow, and the nerves either as sentient or moving organs. The distinction of every part of the nervous system is excitement by stimuli, not acrids only, but every thing generally understood as necessary to life, as food, drink, air, heat, and even volition. As the functions of the nervous system are those of sense and motion, their exercise may be affected by the state of either organ, the state of the brain, or of the nerves in their progress.

The diseases of sensation are in part influenced by the state of the media through which they are conveyed, as those of the skin, the humours of the eye, &c. These will, therefore, give the appearance of different degrees of sensibility, without any disease of the nerves. Different parts of the body differ also in sensibility. The experiments of Haller place the heart in the first rank, and, in succession, the stomach, the intestines, the diaphragm, and the muscles. These have, however, been disputed; but the controversy need not detain us. In the sound state he is not probably in error; but, when inflamed, membranes, and particularly nervous expansions, are by far more sensible than the heart or the muscles. Sensibility also differs in various ages, sexes, temperaments, and idiosyncracies; in pregnancy and child bed, as well as from habit. The state of mind has also a considerable effect on the sensibility; and sympathy, as well as association, often greatly increases it. Dr. Cullen has supposed that the state of the nervous fibril, or the fluid in the nerves, greatly influences the sensibility, and the opinion gains force from the peculiar irritable state of some constitutions, chiefly known by the name of hysterical habits, where the sensibility is considerable. The state of the fibre, as affected by the blood vessels, interspersed, has a similar effect. We have just mentioned the increased sensibility from inflammation, and the professor supposes that the fulness of these vessels gives a greater tension, with which he connects, with great probability, increased sensibility.

Heat increases sensibility, and cold diminishes it. The sensibility is also less in torpid constitutions, in weak states where the circulation is not carried on to the extremities, from the application of narcotics from habit, and the attention strongly directed to some interesting object. Will not a fixed resolution have a similar effect?

Depravity of sense is also an affection of the vital solid, and consists in either a false estimate of the

force of external impressions, or in referring to the external what is owing to the internal ones. This is, however, as we have had occasion to observe, a disease of the brain itself, and owing to an inequality of excitement, or some impediment to the free communication between its different parts. See MANIA.

The diseases of the moving organs are nearly the same in principle, though not in name. These are irritability and torpor, corresponding in their causes, perhaps their nature, to increased and diminished sensibility, and generally connected with the same constitutions. The former is the distinguishing mark of the sanguine, the latter of the melancholic temperament. There is, however, another state consistent with the highest health, which consequently may become disease, and is always a predisposition to disease, viz. the vigour of the muscular fibres, the attendant of the diathesis phlogistica, and in which it indeed consists. But to be more particular.

Irritability is generally connected with the more delicate texture of the solid parts, an increased elasticity of the fibres, peculiar quickness of the senses, a more fluid blood, a tender constitution, a more rapid action of the heart and arteries: it is consequently often hereditary, more frequent in females, in warm climates, those who live luxuriously without exercise, an attendant on inflammatory fevers, and considerable evacuations, the pregnant and puerperal state. The effects of this increased irritability are spasms, convulsions, irregular secretions, and unequal temper, faintings, excessive menstruation, abortions, &c.

The torpor of the living solid is marked by a firmer, ruder texture of the simple solid, sometimes by inflexibility, as in the melancholic, occasionally by a want of elasticity, as in the phlegmatic temperament; by a slower action of the arterial system, by yielding less readily to stimuli, and by a dulness of the intellectual functions. It is the constitution of the inhabitants of higher latitudes, and has been sufficiently considered under the article of COLD, q. v. The effects of this torpor are a diminution of the excretions, with accumulations in the liver and the head, which induce many chronic diseases.

The diseases arising from the state of the brain chiefly depend on its mobility or torpor, as a portion of the nervous system; but more particularly on the free communication between its different parts. The diseases depending on the state of the nerves in their progress depend also on their degree of excitement, or the communication through them being more or less free.

We had intended in this place to have engaged at some length in the inquiry started in the article AS-TRINGENTIA, how far the state of the vital depended on that of the simple solid. We could, however, add little, except to repeat the facts recorded in the pathology of the vital solid; and these seem strongly to support the opinion, that firm cohesion and vigour, a more tender texture and mobility, the first with diminished, the second with increased, sensibility, are at least very closely connected. Are they ever separated, or do they depend on the same state of the solid? Future inquiries may enable us to decide.

MORBI SOLIDORUM CONTINENTIIUM. The containing solids, or the parietes of cavities, are muscular

or membranous; and their size may be, in different ways, increased. When merely dilated beyond what their elasticity or their muscular power can restore, it is styled *dilatatio*; when cavities, as arteries or excretory ducts, are so enlarged as to suffer the contents to pass out, *anastomosis*; when the fibres of cavities are separated so as to suffer fluids to escape through them, *diapedesis*; when ruptured, *diæresis*; if ruptured by distention, *πρῆξις*, if by erosion, *διαβρωσις*. The effects of these changes will be sufficiently obvious; and, indeed, we should not have introduced the subject but to explain the terms.

The diseases from contraction are *obstructio*, when from anastomosis a denser fluid than the vessel is destined to carry passes into it, when its contents are inspissated, or when a solid substance impacts it; *obstipatio*, when the thickened parietes, or any tumour, obstructs the vessels; *compressio*, when cavities are diminished or obliterated by pressure; *collapsus*, when the sides fall in from diminished contents; *contractio*, when diminished from great elasticity or spasm; and *coalitus*, when the sides unite, and are conglutinated.

The morbi solidorum instrumentarii are the local diseases of nosologists, and not a part of this subject.

MO'RBUS ATTO'NITUS, CA'DUCUS, COMMIT'ALIS, HERCU'LEUS, INFANTI'LIS, PUERI'LIS, INTERLU'NIUS, MA'GNUS, SA' CER. See EPILE'PSIA.

MO'RBUS COXARIUS. This is properly the arthro-pyosis, but various circumstances prevented our enlarging sufficiently on it at that time, and we prefer inserting our account of it under this title, as the disease is better discriminated by it from psoas abscess, and from sciatica. De Haen, who first considered it distinctly, also employs this term.

It generally comes on almost imperceptibly. The first sensation is a dull pain, often attributed to fatigue, to a strain, or, in more advanced life, to gout. When the pain becomes so violent as to attract attention, it is described as deeply seated, but on strong pressure it is greatly increased; the glutæi and the vastus internus are flabby; and the glutæus, losing its elasticity, obliterates the line which apparently divided it from the biceps and semitendinosus. The thigh itself is less, though the nates on the side affected are sometimes extended in breadth. In many cases the tubercle of the ischium is lower, and the leg, on the side affected, longer. In general, on walking, the toe drags a little on the ground; and the limb is raised, or extended sideways, with difficulty, though moved circularly with some ease. The pain is not considerable, except in the advanced states of the disease, but it is not confined to the joint. It sometimes extends to the knee, and is felt there with so much violence, as to lead to a suspicion that this joint is the seat of the disease. From the knee it extends to the ankle, but is felt there less acutely. The pain is sometimes on the upper part of the pectinæus, near the place where psoas abscess first appears, and then it descends on the inside of the thigh, nearly in the direction of the adductores of the triceps and vastus externus, almost in a straight line from the knee to the ankle.

For some time the general health remains uninter-

rupted; but, when the disease advances so as to be acutely sensible to the touch, with an acute or throbbing pain, and a redness of the skin, hectic exacerbations come on; the patient starts in his sleep; the face is of a leaden paleness, except when flushed with hectic heat; the skin is clammy; the body wastes, and the strength gradually sinks.

The shortening of the limbs has been esteemed a mark of suppuration coming on; but this is not correct. The limb is sometimes shorter from the beginning, as well as in the advanced stages; nor is any certain consequence to be drawn from this circumstance, unless it suddenly becomes so, when it may give some suspicion of matter having formed.

On dissection, the head, sometimes the neck of the thigh bone, is carious; nor is the change confined to this bone, for the acetabulum equally suffers, and the matter has been found to escape through it into the cavity of the pelvis. Matter in proportional quantities is occasionally found in the cotyloid cavity.

In this disease there is evidently relaxation of the ligament, with a slight inflammation. It probably begins with inflammation of the head of the bone, like that which occurs in the vertebræ, in cases of distorted spine, and gradually presses it downward, upward, or to either side, according to the portion of the head affected; and this will account for all the variety of lengthening or shortening of the limb; for the difficulty of moving the legs sideways and outwards, or for what sometimes happens, of keeping them together.

It is often confounded with rheumatism, and with psoas abscess; but from each may be distinguished by the elongation or the abbreviation of the limb, by the increased breadth of the nates, and the laxity of the glutæi muscles. In the earlier periods also of psoas cases, the difficulty of bending the body, or of putting either leg forward, will sufficiently point out the part affected, while the pain on pressure, dragging the toe, and the relaxation of the glutæi muscles, will sufficiently distinguish it at a subsequent period. In rheumatism also the pain is more extended, the earlier fever more considerable, with often external soreness. At every period of the complaint the prognostic must be unfavourable; but if the constitution is sound, without any scrofulous taint, the disease incipient, and the patient willing to pursue the necessary plans, we sometimes succeed. Even when suppuration has come on the patient may escape, but it must be by the efforts of nature alone. In such cases the abscess occasionally bursts, though this sometimes does not occur, and the matter is absorbed. In each circumstance the most absolute rest, free country air, a milk diet, keeping the bowels free, with the occasional use of the bark, are chiefly useful. If any thing is more essentially necessary than the others, it is absolute rest, with free country air. If any thing is less so, it is medicine. A stiffness of the joint is, however, the inevitable consequence.

The causes appear to be most generally cold, from damp beds, and lying in damp sheets. Blows and strains also induce it; but in children it often comes on without the known influence of either, and seems to be of a scrofulous nature, as it chiefly affects

those whose appearance shows the seminium of that disease.

The cure of the disease, in the earlier or middle stages, requires peculiar attention in the practitioner, and no little resolution in the patient. Inflammation, we have said, is the first symptom, and bleeding with leeches, a moderately low diet, occasional doses of neutral salts, together with the continued discharge of a blister, will succeed. If the season permit, sea bathing or cold pumping will complete the cure. In this state, also, a light infusion of the bark, or any other bitter, seems to have been of service. Should, after a trial of this plan, the disease continue, or seem to increase, an issue should be made just behind the great trochanter. The application of a caustic will, on the separation of the eschar, form a deep sore, which should be so large as to require, both in breadth and depth, a horse bean for its continuance. Tenderness is in this case cruelty: it should be done effectually, or wholly omitted. If the pain and fever have not been violent, or have been mitigated by the usual remedies, sea bathing may be continued with this issue, as it can be easily covered by leather spread round its margin with sticking plaster. Some surgeons have recommended a seton; but the cord does not penetrate so deep, and cannot be so conveniently covered to admit of sea bathing, which is a most essential remedy.

Instead of leeches, cupping glasses have been recommended; and instead of blisters, the lime poultice, made of one part of quicklime slacked in the air, with two parts of oatmeal, made into a poultice with hogs' lard. These are less effectual remedies, though sometimes useful in irritable habits, where the terror excited by the more acute remedies might be injurious. They should be trusted, however, only in the slightest cases. Opiates, particularly in the form of Dover's powder, may, at any period of the disease, be allowed with safety; and often when the pain is violent with advantage.

Though we have chiefly trusted sea bathing and cold pumping, yet the annals of the Bath hospital speak with confidence of the utility of warm pumping; and Dr. Falconer has lately given a very satisfactory view of its utility. The Bath waters can only be admitted when fever has not come on, or when it has been checked by the appropriate remedies. If the patient be tolerably strong, and the symptoms moderate, the bath of 105° is used two or three times a week, and the patient continues in it from fifteen to twenty-five minutes. After bathing a few times, on the intermediate days, the part is pumped on for about five minutes, when the patient receives 500 strokes. From this remedy the stiffness and pain are relieved, the soreness and swelling diminish, the strength and plumpness of the limb gradually return, and the leg, whatever was the change, resumes its natural length and direction.

A similar application of hot water has been attempted at a distance from Bath; but whether it arises from the heat employed being too low, or that the Bath waters derive, in part, their virtues from the mineral impregnation, is uncertain; the effects, however, have not answered the expectations of the practitioner. The warm sea water bath promises to be very useful, and to this a pump may be readily adapted.

If the suppuration proceeds, notwithstanding every

effort, we have already remarked that nature must effect a cure, if the patient ever attains it; and the plan has been sufficiently detailed.

Mo'RBUS NI'GER. The BLACK DISEASE, *melæna* of Sauvages, *melaina nosos* of Hippocrates, of which he describes two kinds. In the first the patient vomits black bile, sometimes bloody and sour; a thin saliva, or green bile. The acrimony of the fluid occasionally inflames the mouth, and its acidity affects the teeth in the usual way. Vomiting relieves, but flatulence affects the patient when empty, and a great load is felt after eating. A slow fever, head ach, dim sight, heaviness in the legs, and blackness in the skin, are common symptoms. Frequent cathartics, with whey, milk, and other diluent drinks, are only necessary. The second kind consists of a discharge of concrete blood of a blackish red colour, mixed with a large quantity of insipid, acid, or viscid phlegm, thrown up by vomit. This evacuation is generally preceded by a pungent tensive pain in both hypochondria, and the appearance of the disease is attended with anxiety, a compressive pain in the præcordia, and fainting, which last is more frequent, and more violent, when the blood evacuated is fetid and corrupt.

In modern authors, every dark coloured discharge has this appellation, and little care is taken to distinguish its source. A black discharge may be either bile or blood. Each is distinguished by the colour when diluted, for bile is of a dark yellow, and blood is red. But in worn-out constitutions the bile will not always assume on dilution the yellow hue; and in this case the black matter consists of dark flakes, or sometimes a dark pitchy matter is discharged. The latter appearance is not indeed a diagnostic mark, for it is the colour of the meconium in young children, and is the substance often discharged after long continued constipation.

When these distinctions are kept in view, the practice is easy. The discharge of blood is either an active or a passive hæmorrhage, generally passive, and in neither case highly dangerous. Indeed we have seen very considerable discharges of blood by stool, from strains in the young and active, yield to nitre, to opiates with occasional mild laxatives. The passive hæmorrhages require astringents, with the vitriolic acid. The blood in these cases flows from different arteries, and its source requires no variation of practice.

When the bile is dark, a previous suppression has usually occurred; and the discharge, which is essentially necessary, must be regulated by the strength of the patient. The pitch-like bile, or perhaps the grumous blood, requires also to be evacuated; and the best medicine for each purpose, if the strength of the patient will admit, is calomel. This medicine, were we to revive the term, we should style the true cholagogue. But the pitchy and the flaky bile, in worn-out constitu-

tions, must be gradually discharged, and the strength supported by wine, by nourishing diet, by aromatics, and by any thing but astringents.

Pains are uncommon; and if they occur, must be obviated by fomentations, and by opiates. They are truly spasmodic, for inflammatory pains only attend inflammation of the membranes of the liver.

The discharge from piles sometimes resembles the *melæna*; but the pain, at the lower part of the rectum, the fulness and tension, sufficiently distinguish them.

See Hippocrates, lib. ii. De Morbis, sect. v.; Hoffman, Rationalis Medicina Systema; Edinburgh Medical Commentaries, vol. iv.; London Medical Journal, vol. i. p. 10.

MORDE'HI. A disease to which the East Indians are subject. It is a fever seemingly from bile in the stomach. See F. Hoffman, De Morb. Epidemicis.

MORDE'XYN. A disorder very common at Goa, which seizes the patient suddenly, attended with a continual nausea and vomiting; and often proves fatal. F. Hoffman, De Morbis Epidemicis:

MORHU'A. See ASELLUS MAJOR.

MORI'LE. See AMANITA.

MORI'NA. A plant, named in honour of Dr. Morin of Paris. *Morina persica* Lin. Sp. Pl. 39, said to be cordial and perspirative.

MORI'NGA. *Guilandina moringa* Lin. Sp. Pl. 546. A large tree in Malabar and Ceylon, whose fruit is a foot long, angular, as thick as a carrot, and delicious to the taste. The leaves, root, bark, and fruit, are said to be antispasmodic and sudorific. See Raii Historia.

MO'RO (from *morus*, a mulberry). An abscess in the flesh, resembling a mulberry.

MOROCTHUS. See OMOROCTHUS.

MORO'SIS, (from *μαρος*, foolish). STUPIDITY, IDIOTISM. This may be styled a mental disease, sometimes owing to a more slow expansion of the mental faculties, which often, however, attain their powers suddenly, and in perfection, as suppressed irritability is followed by excess of excitement. When the mental powers are developed slowly, we often find a defective conformation of the cranium, and particularly an elongation of the upper part, while the sides are unusually depressed. Pinel, who scarcely admitted any organic defect to produce mania, admits it as a cause of idiotism. When in a less degree, it is not connected with any defective organization which the knife can discover.

Dr. Cullen considers this disease as synonymous with AMENTIA. Sauvages makes it a species of AMENTIA, and defines it a slowness or inability in the faculty of imagining or conceiving; consequently a debility in judgment without delirium. Stupidity differs from folly, as stupid or idiotic persons want both conception and memory. See AMENTIA.

MOROSITA'TES, (from *morosus*, peevish,) are diseases wherein the desires and aversions are unnatural and depraved, and in which it is difficult to please or satisfy. A morose man, speaking of him in a state of disease, constantly requires what is injurious, and is averse to what would be beneficial. In Dr. Cullen's system these diseases are synonymous with *dysorexia*, appetites cronnous and defective. In the last editions they are included under the class *locales*, because almost all the species of *dysorexia* are affections of a

particular part rather than of the whole body. The nostalgia alone, if it can be called a disease, cannot be esteemed a local one; but he thought he could not well separate an uncertain disease from the rest of dysorexies. See *Nosologia Methodicæ Synopsis*, vol. ii.

MORPHÆ'A, (*μορφαία*, from *μορφή*, *forma externa*). MORPHEW, SCURF, a species of the leprosy seated in the skin. The brown itching morphew is named *hepatizon*.

MORPIO'NES. CRAB LICE, so called from their resembling crabs: *pediculi pubis* Lin. *plactulæ*, *petolæ*, *fessolatæ*. They are flattish, more round than the common lice, with a shorter thorax, and the four hinder feet, very strong, perforate the cuticle, and stick so close that they can be with difficulty dislodged. They do not only affect the pubes, but the axillæ, eye brows, and eye lids, and are often found on the breast, abdomen, thighs, and legs, in persons who have those parts covered with strong hair; but they seldom fix upon the hairy scalp. They occasion considerable itching, which may be cured by destroying them with black soap, or a solution of sublimate in rose water, in the proportion of ʒ ss. to ℥ i. of the water: strong mercurial ointment is an effectual remedy. See *PEDICULUS*.

MORS. See *DEATH*.

MORSE'LLUS, or MORSU'LUS, (a dim. of *morsus*, a bite). See *TROCHISCI*.

MORSU'RA, (from *mordeo*, to bite,) a BITE, generally applied to the bite of a mad dog, a viper, or any venomous animal.

MO'RSUS, (from the same). A BITE, or PAIN resembling that from a bite of an insect.

MO'RSUS DIABO'LI. See *TUBÆ FALLOPIANÆ*, or *DEVIL'S BIT*, and *SUCISA*.

MO'RSUS GALLI'NÆ. See *ALSINE*.

MO'RSUS RA'NÆ. See *MICROLEUCONYMPHÆA*.

MORT DE CHIEN. A spasmodic disease of peculiar violence and obstinacy, not generally understood. The name is assigned by the seamen, who probably consider this disgraceful termination of their lives as the *death of a dog*. The disease is mentioned by Bontius, and by Mr. Girdlestone; but considered more distinctly and accurately by Mr. Curtis in his account of the Coast Diseases of the East Indies. It is a violent spasm affecting not only the extremities, but the bowels, drawing the intestines into a hard knot, attended with great coldness and debility, and within a very short period fatal. It has been attributed to acrimonious bile; but previous evacuations do not prevent it, nor emetics, with purgatives, relieve it. External warmth, with the most active stimulants, and opium, in very large doses, appear to have been the most useful remedies. See *Curtis's Account of the Coast Diseases of the East Indies*.

MO'RTA. Synonymous with *PEMPHIGUS*.

MORTARIO'LUM, (dim. of *mortarium*, a mortar). In chemistry, a mould on which cupels are formed; in anatomy, the sockets of the teeth. See *ALVEOLI*.

MORTIFICA'TIO, (from *mors*, death, and *fiō*, to produce). A MORTIFICATION. *Sphacelus*, *ignis frigidus*. Hippocrates uses *sphacelus* in different senses, sometimes confining it to a corruption of the bone, which, in the language of Celsus, is called *vitiari*; but these words are used in general to express the corruption of the flesh as well as bones. A mortification of the soft parts only Hippocrates styles *sapron*, *mydosen*, and *sephenon*. The word *sphacelus* was used by the

ancients to express violent pains and inflammations terminating in mortification, as well as the withering of any part. Galen confines the term *sphacelus* to an incipient gangrene.

Boerhaave considers gangrene as a beginning mortification. Mr. Pott calls it gangrene in the cellular membrane and the skin, but when attacking the muscles, *sphacelus*. A mortification in the bone is called a *caries*. Dr. Cullen considers the mortification not as a genus of disease, but as a termination of inflammation; and he divides it into gangræna and *sphacelus*. In the first, after an inflammation, the part becomes livid, soft, has little sensibility, and is often covered with ichorous vesicles; in the second after a gangrene, the part becomes black, flaccid, easily lacerating, without sensation or heat, and attended with the factor of putrid flesh; the malady quickly spreading: the latter is, therefore, an higher degree of the former.

A mortification is, the death and consequent putrefaction of one part of the body while the rest is alive. Celsus describes its progress in the following terms. The flesh is black or livid, dry or parched, and the external skin generally full of blackish pustules: then that which is next to it is pale or livid, almost æruginous, and without sensation. It is still worse in an inflammation, since all the symptoms spread at once, the ulcer into the pustulous place, the pustules into that which is pale and livid, the pale or livid into that which is inflamed, and that which is inflamed into that which is sound.

It is singular that this subject has so long remained in a state of so much confusion, not only with respect to its nomenclature, but to its causes and treatment. We have found in no author a connected and systematic view of the subject; and we must, therefore, on this, as on several other occasions, endeavour to unite the scattered limbs and supply the deficient links. In this enquiry we shall employ the term mortification as a generic one.

The simple idea of mortification is, as we have already said, the death of a portion of the body while the rest continues alive, often in a sound state. This partial death may arise from general or local causes. The general causes are fever, or great debility; each occasionally attended with a dissolved state of the fluids. Fevers attended with mortification are the violent inflammatory ones, with local inflammation, or the jail and hospital fevers. Diseases of debility are those of old age, anasarca, scurvy, bruises, and causes which check the circulation of the blood, or impede the nervous influence. In these cases, the life of the part is destroyed by the violent excitement, or the tone of the constitution gradually diminished, by advancing age, a sedentary life, or an unalimentary diet. In internal inflammations we cannot see the progress, but it is probably the same as in the external parts. In the latter the pain ceases, the purulent matter becomes acrid and sanious; air bubbles are set at liberty, collecting in small vesications, under the skin, or distending the whole organ by an emphysematous swelling. A slight delirium comes on, with either dejection of spirits, or with a calm serenity of mind; but, in each case, attended with a peculiarly wild expression of countenance; though sometimes with a very peculiar expression of serenity, with a blackness under the eyes. The pulse is usually quick,

low, and often intermitting. In the earlier stages, deep incisions are attended with a discharge of blood still florid; but the skin, the muscles, and the cellular membrane, soon melt down into a brownish offensive mass. See INFLAMMATIO.

In the jail and hospital fevers, depositions sometimes take place, resembling, at first, in appearance, critical abscesses, but rather of the nature of the anthrax or carbuncle, running rapidly into mortification; and, when these do not appear, discolorations, apparently slight will be observed on the skin, which often run deep, and the mischief is concealed till no longer within the reach of art.

Mortifications, from debility, are frequent in old age, and these are sometimes chiefly local. When attended with great pain, they are highly distressing; but they sometimes occur without being perceived. Mr. Pott first pointed out the painful kind, as the subjects of treatment different from that which had been usually recommended: the other kinds are the *dry*, and what has been styled the *white gangrene*. In the *dry gangrene* the parts shrivel, the fluids are observed, but no putrefactive fermentation can take place without moisture. The part remains attached, for a time, like an extraneous one, and may be amputated above the mark, which separates the dead from the living portion; but nature at last often makes the separation, as in other gangrenes. The *white gangrene*, sometimes mentioned, seems rather to be a paralytic insensibility than truly gangrenous.

In general, the topical gangrenes of advanced life are owing to ossifications of the arteries, and we suspect the pains attending those described by Mr. Pott are owing to the effort of the arteries above, endeavouring to conquer the obstruction. We have instances of similar pains in paralytic limbs, when sensation is recovering, and in anasarcomous ones, when the water is removed. What adds to the probability of the cause is, that the pains occur some time previous to the darkness appearing on the skin, which is usually first observed between the toes.

Water, collected for a long time, in the lower extremities, presses on the nerves and arteries, destroying both sensibility and irritability. In such cases, a slight wound often becomes gangrenous, and the vesicles, raised by the water, and by which it is occasionally discharged, sometimes cover a deep mortification. Such consequences are not, however, common, and when mortification, in such instances, does follow, it is superficial, and often easily removed. See ANASARCA.

In scorbutic habits, particularly in sailors after long voyages, in soldiers from an unhealthy encampment, or after a siege, and in prisoners after confinement, ulcers break out chiefly in the lower extremities, which discharge a thin ichor, and sometimes terminate in mortification. Instances are also recorded of mortifications rapidly coming on without any evident cause.

Other causes are ligatures, wounds, fractures, where the soft parts are greatly bruised or lacerated; aneurisms, or ruptured arteries, with whatever impedes the influence of the nervous power, or the flow of blood from the heart. From these causes, mortification often occurs in palsied limbs, or is the effect of severe long continued cold, q. v. Compression of the spinal marrow in cases of distorted vertebræ, or of other tumours in the

course of the larger nerves, equally produce it, by first inducing palsy.

The event of mortification is always doubtful; and when the cause is irrecoverable debility, obstructions which art cannot remove, or ossifications of the arteries, we can scarcely expect a cure. Internal mortifications are usually beyond the reach of medicine; yet we see in cases where the operation is performed for strangulated hernia a beginning blackness, not followed in some cases by any fatal event; and find that even a portion of intestine may be thrown off, after intususceptio, in which internal mortification must have preceded. We should not, therefore, relax in our efforts, when appearances of internal mortification have come on; and, in fact, we find in enteritis the most threatening symptoms of this kind apparently relieved.

The most important symptom to guide us in cases of mortification, is the appearance of separation. When the general principle of the disease, in the constitution, is checked, a red line, sometimes considerably above the mortified part, appears. At this line the dead part drops from the living; and, when it is discovered, amputation above that line will greatly save the strength of the patient: were the natural separation suffered to go on, amputation would be afterwards necessary, if the stump is expected to be ever useful. In cases, however, where, from the violence of the bruise, mortification appears inevitable, amputation, previous to its coming on, will succeed, at no great distance from the wounded part, if above the place where it is bruised, or to which inflammation has extended.

When mortification appears to have taken place after internal inflammation, we have said our endeavours must not be relaxed, but we must check all evacuations, and support the strength with more generous nourishment, give wine so far as the original disease will permit, occasionally bark, and more certainly opium.

In external mortifications, from inflammation, it has been common immediately to give bark. But this is not always necessary, and sometimes injurious. If the increased action of the vessels still continues, it must be moderated by a stimulus, a little below that which supports the inflammation; and it is in this state that the application of a solution of muriated ammonia with vinegar is peculiarly useful. At this period also, opiates will be advantageous. When the disease has proceeded farther, and the part is wholly dead, the warmer applications, soon to be mentioned, will be necessary. It has been usual to direct, in such cases, incisions or scarifications down to the living portion of the limb. It has been practised, and opposed, without sufficient foundation. It is often useful to admit of the access of the stimuli to the living part, to assist the separation; and there is no danger from the absorption of the putrid matter, as has been supposed. Yet, on the whole, the advantages of this plan, in practice, do not appear to be considerable.

In those mortifications which attend jail and hospital fevers, the bark, with cordials, each in the fullest doses, are absolutely necessary; nor are there any limits to the exhibition, but what arise from the situation of the patient. In such cases, all abscesses must be opened very early. We cannot wait for a proper purulent matter, which nature is most frequently unable to form; for the discharge is most often fetid and sanious.

The topical mortifications are most frequent; and, in these, Mr. Pott has taught us the superior advantages of opium. In general, this medicine is indicated when great pain has preceded; and it is probable that, as excess of contraction lessens the irritability of muscular fibres, so excess of excitement will impair the nervous energy. Opium, therefore, as diminishing the cause, will contribute to lessen the effect. Whether opium will add to the efficacy of other medicines, or will, alone, relieve diseases of this kind, has not yet been ascertained. We have reason to think it will prove a useful addition, in the greater number of cases.

If opium fails in the painful gangrenes, proceeding from ossifications, we know not what can be substituted. Bark, wine, and other cordials will have little effect; nor will any thing succeed but amputation. Where, however, must we amputate, or where does ossification end? and in an old, worn out, debilitated frame, is the operation advisable? To add a few weeks to a decaying constitution will not justify what Dr. Aitkin calls an *Herculean experiment*.

The rest of the practice is empirical. Bark, wine, ardent spirits, and opium, must be given in doses equal to the emergency, and often accumulated with great rapidity. It might perhaps render the practice less empirical, if surgeons were to distinguish more accurately when stimulants and when antiseptics were necessary. The list of stimulants is unusually long; but the order indirecta, including wine, alcohol, &c. is of equivocal use, as followed by loss of tone, unless the application is continued. As powerful antiseptics also they have been preferred, and we should also remember, that in general, when the disease is first checked, nature exerts all her powers to continue the salutary process. We add to the antiseptic power of these stimulants by camphor, which may be properly combined with them, and sometimes by the warmer essential oils, which may perhaps be more often used with advantage; and the effects of all are increased, by their being heated to a degree so high as the patient can bear. In local mortifications from debility, the antiseptics are often only necessary; and of these the myrrh is frequently very useful, and in cases of a high degree of fætor, the carrot poultice, the charcoal, the effervescing poultices, particularly with the oak bark, and the cummin seed, are highly advantageous. In every situation of this kind, however, the constitution must be supported, by a generous diet; by wine, frequently by bark.

In many instances, the bark is inadmissible, either from fulness, asthma, or other constitutional complaints. In these circumstances, wine, probably opium, ammonia, with stimulant applications of the greatest efficacy, must be employed. We have not found that the other bitters will supply the place of the bark; but the camomile flowers have been recommended, though modern practice appears to rank them among the more inert remedies.

Antiseptic poultices are of different kinds. The astringents, of which the chief is the oak bark, are highly useful; and this, joined with fermenting substances, is often highly useful. The addition of charcoal is said to correct the fætor, and it may add also to the antiseptic power. Since, however, it was introduced by the recommendation of the first Monro, the bark has been implicitly trusted.

We might add a hint, that amputation has been often employed too early, and that ecchymosis has been mistaken for mortification. Yet, as we can lay down no general rules for the conduct in cases of emergency, we would not insinuate doubts which might be prejudicial to the character of the surgeon, without reason or foundation.

The tendency to mortification from scorbutic affections must be obviated by fresh vegetables, and the native vegetable acids. Those from tumours of the spine or other parts, from palsies, &c. must be relieved by remedies adapted to the original affection.

Boerhaavii Aphorismi. Hildanus de Gangræna et Sphacelo. Heister's Surgery. Kirkland on Pott's Remarks on Fractures. Pott's Works. Bell on Ulcers, edit. 3. p. 93—122. Kirkland's Medical Surgery, vol. ii. p. 291—433. London Medical Transactions, vol. iii. p. 47. Pearson's Principles of Surgery, vol. i. p. 105. White's Surgery, p. 8.

MO'RTUA TE'RRÆ. See CAPUT MORTUUM.

MO'RUM, (from *morus*, a mulberry). An excrescence on the surface of the skin in many parts of the body, resembling a mulberry. When on the eyelids, the Arabians call it *alchute*.

MO'RUS, (from the Hebrew term *mora*, black). The MULBERRY TREE, *morus nigra* Lin. Sp. Pl. 1398. Its fruit hath the common quality of all sub-acid fruits, quenching thirst by their coolness, and by exciting an excretion of mucus in the mouth; a similar effect is also produced in the stomach, where they also correct putrescency, which occasions an uneasy clammy sensation in the fauces. A syrup is prepared from this fruit, though but little used. See Raii Historia. The bark of the root of the mulberry tree has an acrid bitter taste, is said to be a cathartic, and has been used with success as a vermifuge, particularly in cases of the tape worm, given in powder, in the dose of half a drachm.

MO'RXI. A pestilential distemper very common in Malabar and other parts of the East Indies.

MO'SA. A liniment used in Germany, made of wheat flower and milk, nearly of the consistence of thin paste.

MOSCH. The roriferous vessels, which Bilsius thought that he had discovered, but never demonstrated. Castellus.

MOSCHATELLI'NA, *adoxa moschatelina* Lin. Sp. Pl. 527, *ranunculus nemorosus*, *aristolochia rotunda*, *concava*, *denticulata*; a diminutive from *moschus*; called so in consequence of its smell. The root is supposed to be resolvent and detergent. See Raii Historia.

MO'SCHUS, (from the Arabic term *mosch*). МУСК, *amisa*, is an odoriferous gumous substance, an inspissated secreted fluid of the *moschus moschiferus* of Linnæus, and the *Tibet musk* of Pennant. This animal is of the deer kind, and the drug is found in a follicle of the size of a hen's egg, on the belly of the male only. The bag is kidney shaped, pendulous, opening by two small orifices; a naked oblong one, and another smaller with long hairs. The best musk is brought from Tonquin in China, in thin bags, with brownish hairs; an inferior sort from the East Indies is in bags with white hairs. Neumann thinks both equally good.

The best musk is dry, with a kind of unctuousity, of a dark reddish brown colour, in small round grains, with very few hard black clots, perfectly free from any sandy

or other visible foreign matter. Chewed and rubbed with a knife on paper, it is bright, yellowish, smooth, and free from grittiness. Laid on a red hot iron, it flames, and burns almost entirely away, leaving only an exceedingly small quantity of light greyish ashes. The taste is bitterish and subacid, the smell highly fragrant, in small quantities, or at a distance. Rectified spirit of wine takes up the whole of the active part; but the smell is only discovered on dilution: a drop or two communicates to a quart of wine, or to water, a rich scent. The quantity of liquor which may thus be flavoured by a certain known proportion of musk is the best criterion of its goodness. With water it is mixed only by the intervention of mucilage, as in the following preparation.

MI'STURA MOSCHATA, formerly *Julépum à moscho*. —Take of rose water, six ounces; of musk, two scruples; of the mucilage of gum arabic, and of double refined sugar, of each one drachm; grind the musk with sugar, then with the gum, and add the rose water by degrees. Volatile spirits enable the water to suspend or dissolve more of the musk; and two drachms of the volatile spirit may be added to the above mixture. Dose, two or three table spoonfuls. In distillation, however, water carries over all the odoriferous matter, while the rectified spirit scarcely conveys any portion of it.

Though the smell of musk sometimes disorders those who are peculiarly sensible and irritable, yet, when taken inwardly, it abates those symptoms which its smell produces. It is one of the principal antispasmodics; but its advantages are often lost by giving it in too small doses. Dr. Wall informs us that two persons, labouring under a subsultus tendinum, extreme anxiety, and want of sleep, occasioned by the bite of a mad dog, were perfectly relieved by two doses of musk of sixteen grains each; adding that convulsive hiccoughs, attended with the worst symptoms, were removed by two doses of ten grains each. When, on account of convulsions, no medicine could be given at the mouth, musk succeeded in a clyster; and those who were averse to perfumes, expressed no objection to it in a bolus; but under six grains he never saw any benefit by its use. Ten grains and upward promoted usually a diaphoresis without heating or giving any uneasiness: on the contrary, it abates pain, raises the spirits, and, after the sweat begins, promotes sleep; and in maniacal cases hath afforded a temporary relief. Dr. Owen, of Shrewsbury, relates a singular instance of success from yet larger doses, viz. of half a drachm every four hours, in a convulsive disorder, after all the usual methods had failed. See London Medical Observations and Inquiries, vol. iii.

Though we highly respect these authorities, yet our own experience does not support them in their full extent, which may probably be owing to the medicine not being genuine. In large doses it is said to procure sleep, and as certainly to occasion a profuse sweat. It has been hence considered as a sudorific, and given in the latter stages of fever, particularly where subsultus and convulsions had come on. In gout retroceding to the stomach or head, and in delirium, it is also said to be a valuable medicine.

Some practitioners consider musk as a medicine of little or no consequence; but for what reasons it is difficult to determine, since the experience of every day

proves it certainly a diaphoretic and antispasmodic, given in such doses as are properly adapted to the constitution of the patient and nature of the complaint; but, on the whole, it is not a very certain or a very powerful medicine.

See Lewis and Cullen's *Materia Medica*, and Neumann's *Chemical Works*.

MO'SCHUS A'RABUM. See ABELMOSCHUS.

MO'SCHUS A'RTIFICIALIS, is a medicine lately introduced from Germany. Four ounces of nitrous acid are added to an ounce of oil of amber, constantly stirring them; and the result is a spongy mass, highly fetid, but resembling in smell nitrous oxide rather than musk. This preparation has been for some years known, and was introduced as a medicine for the whooping cough; but, even among the young, sanguine innovators is now seldom heard of.

MO'SE HAZUA'NIA. See ENDICA.

MOSQUITÆ. A cutaneous disorder in the East Indies, sometimes produced by sweating, sometimes by the bite of an insect of this name, *mosqueta*. With the pimples an itching comes on, succeeded by an ulcer. When from sweating, the relaxant or diapnoic sudorifics are useful; and the itching is allayed by washing with vinegar in which nitre is dissolved, or with which lime juice is mixed. See Bontius de *Medicina Indorum*.

MOSY'LLON, (*μουλλων*). See CINNAMOMUM.

MO'TA. See CASTANA.

MOTO'RES OCULO'RUM, *motorii oculorum communes, oculares communes*, and *oculo musculares*, are the third pair of nerves from the head, which pierce the dura mater by the sides of the sella turcica, run through the foramen lacerum orbitale superius, to all the muscles of the eyes, except the obliquus superior and abductor of each. They likewise supply the levator palpebræ superioris, and send twigs to form the ciliary nerves, to the choroides and iris.

MOTO'RES OCULO'RUM EXTERNI, *oculares externi, ophthalmici externi, orbitarii*, and *oculo musculares, externi*, are the sixth pair of nerves that go out from the head to the abductores oculorum, running forward on the side of the cella turcica, and getting into the orbit by the foramen lacerum orbitale superius. By the side of the sella turcica they give off what is called the beginning of the intercostal nerves, but they are more properly branches of the intercostal, which join these nerves.

MOTO'RII. See SPASMUS CLONICUS, and MOTORES OCULORUM.

MO'TOS, LINT, (*μολος*). See CARBASUS.

MOUL-I'LA seu MOUL-ELAVOU, the INDIAN LEMON TREE, *bombax ceiba* Lin. Sp. Pl. 959, the fruit of which is both acid and aromatic, like the pepper. See Raii *Historia*.

MOUNT-SION WATER, a chalybeate, which seems to retain for a long time its ingredients, without decomposition. See an *Essay on the Liverpool Spa Water*, by T. Houlston, M. D.

MO'XA, (a Japanese term,) *artemisia vulgaris* Lin. Sp. Pl. 1188, *musia-pattra*, МОХА, is a soft lanuginous substance, prepared in Japan from the young leaves of a species of mugwort, by beating them, when thoroughly dried, to separate the fine lanuginous fibres, which are then formed into small cones. The

down on the leaves of mullein, cotton, and hemp, are not greatly inferior.

In the eastern countries, when the actual cautery is required, a little cone of the *moxa* is laid upon the part, previously moistened, and set on fire at the top: it burns down with a temperate glowing heat, and produces a dark coloured spot, the exulceration of which is promoted by applying a little garlic. In Asia this kind of cautery is employed in preventing and curing many complaints, particularly chronic rheumatisms, gout, the morbus coxarius, and other painful affection of the joints. See Kämpfer Amœnitates Exoticæ, p. 502, &c. Abbé Grosier's History of China.

MUCA'GO, (from *mucus*, *mucilage*). See MUCILAGO.

MUCHA'RUM. A barbarous word, signifying an infusion of roses, in warm water, reduced to a syrup, with sugar.

MUCIFLU'XUS ACTI'VUS, and PASSI'VUS, (from *mucus*, and *fluo*, to flow). See GONORRHEA.

MUCILA'GO, (from *mucus*). A MUCILAGE; *mucago*, a viscid glutinous liquor, made by dissolving the gum, or the soluble part of gum arabic, quince seeds, &c. in water.

Young plants particularly abound in mucilage, and seem to consist of it almost wholly. In the mallows, lintseed, and some of the cryptogamiæ, as the lichens, confervæ, and mushrooms, it is almost uncombined: in the milky plants it is in part separated, and united with oil and water. In every instance, it seems to be formed independent of light, which is rather an ingredient of the gluten. It is occasionally united with sugar, sometimes with oil, forming what are styled *fat oils*. It is insipid; soluble in water; insoluble in alcohol; coagulated by weak acids, and metallic solutions; not inflammable, but almost wholly exhaling in carbonic acid gas; changeable by the nitric acid into the oxalic, and by the muriatic into the citric acid. When diluted with water it becomes acid, and, in distillation, gives over the pyromucus acid.

The fluid, separated from the glands about the joints to facilitate their motion, is styled *mucilage*. See SYNOVIA.

MUCILAGINO'SA LIGAME'NTA. See CAPSULARIA LIGAMENTA.

MUCILAGINO'SA EXTRACTA, are what the French chemists have styled *extractive matter*. They are the mucilage of the plant, united with its proper juices, scarcely changed by heat.

MUCOCA'RNEUS, (from *mucus*, and *caro*, *flesh*), *myxo sarcoma*, an epithet for a tumour, or abscess, partly fleshy, and partly mucous. Severinus.

MUCO'SÆ GLA'NDULÆ. See COWPERI GLANDULÆ; sometimes the name of the conglobatæ, to distinguish them from the glandulæ conglomeratæ, called VASCULOSÆ.

MUCO'SUM LIGAME'NTUM, a ligamentous cartilage, and full of mucus, situated betwixt each vertebra, admitting them to recede from, or approach nearer to, each other. To their elasticity it is owing, that at night a man is somewhat shorter than in a morning.

MUCRONATI, (from *mucro*, a sharp point). Leaves or fruits of plants terminating in a point, termed mucronated. Mucro is also the sharp point of the heart.

MUCRONATUM OS. See ENSIFORMIS CARTILAGO.

MUCU'NA GUA'CU, *dolichos urens* Lin. Sp. Pl. 1020. The largest and most beautiful kind of phaseolus in Brasil; growing also in Malabar. The beans are poisonous, but easily rendered fit for food. See Raii Historia.

MU'CUS, (from the Arabic *muk*), *myxa*; *myxara*; *myxas*; the viscid fluid which covers the surfaces of all the membranes, exposed to any extraneous matter, as the skin, internal membrane of the mouth, nose, lungs, œsophagus, stomach, intestines, urinary passages, &c. It is thin at its first secretion, but more viscid apparently from its union with oxygen, colourless, insipid, inodorous, and incapable of stimulating; but if its secretion is suddenly increased, it becomes a watery acrimonious fluid of a whitish or a greenish yellow colour, sometimes acquiring a smell, and occasionally the appearance of pus. In its natural state it contains some common salt and phosphat of soda, inviscated in albumen. From Dr. C. Darwin's Experiments, which Dr. Darwin himself has since claimed, it appears that, if any suspected matter be in separate equal portions, dissolved in vitriolic acid and caustic alkaline lixivium, water will precipitate any pus which exists. Pure pus will not dissolve in a dilute alkaline solution. But an experienced eye requires no such assistance.

MU'FFLE, in chemistry, a little oven, in which tests or cupels are placed to defend the metals in assaying from the contact of the fuel.

MU'GILIS, (*à muco*, from its viscosity). MULLET. *Mullus* Lin. Syst. Nat. the cephalus of Aristotle and the Greeks, the cestreus of Oppian and others. It is sufficiently soluble, and nutritious. The Romans valued a fish of this name highly for its exquisite relish, which was probably the sur-mullet of the western coasts of the channel, an exquisite dainty, which will not, however, bear carriage. See DIÆTA.

MU'LE. Pustules contracted either by heat or cold.

MULE, any production between individuals of different species; sometimes styled hybrid animals, or plants. The species must be nearly related, or generation will not take place, and mules of either kind are generally barren.

MU'LSUM, (from *mulceo*, to refresh). *Hydromeli*, HONEY and WATER. *Acratomeli* signifies wine sweetened with honey.

MULTICAPSULA'RES PLA'NTÆ, (from *multus* and *capsula*), such plants as have several pods of seeds succeeding each flower.

MULTI'FIDUS SPI'NÆ, MU'SCULUS, (from *multus* and *findo*, to cleave,) lies under the spinalis; rises from the roots of the transverse processes, and runs to those of the spinal processes: it is commonly called *transversalis*, distinguished into the *transversalis colli*, *dorsi*, and *lumborum*. The last is also called SACER; q. v.

MULTIFO'RME OS, (from *multus* and *forma*). See CUBOIDES OS.

MULTISI'LIQUE PLA'NTÆ, (from *multus* and *filiqua*), plants which have after each flower many distinct, long, slender, often crooked seed pods. It is the name of the twenty-third order in the Fragments, and

of the twenty-sixth in the *ordines naturales* at the end of the *genera plantarum*.

MUM. A bitter infusion in beer, to which the ingredients are added, generally while the beer is fermenting, though it is sometimes made extemporaneously by adding a bitter tincture. It is a German liquor, introduced to us from Brunswick, and is there said to be made in the following manner:

Sixty-three gallons of water are boiled to forty-two, and with this seven bushels of malt, a bushel of oatmeal, and as much of ground beans, are brewed in the usual manner. When the fermentation begins, three pounds of the inner rind of the fir, one pound of the tops of fir and beech, three handfuls of *carduus benedictus*, two of the flowers of *rosa solis*, a handful and half of burnet, betony, marjoram, avens, pennyroyal, and wild thyme, two handfuls of elder flowers, thirty ounces of cardamoms, and an ounce of bruised barberies, are added. The herbs and seeds, however, are put in the hogshead after the fermentation has continued a little time. When stopped, ten new laid eggs unbroken are added, and it is kept two years before it is drunk.

The English brewers chiefly use cardamoms, ginger, saffras, elecampane, and for the colour, madder or red sanders. It is a warm carminative, useful in weak and gouty stomachs, used by common labourers as a warm stimulating liquor in the morning, chiefly to restore the tone of the stomach after excess. It was formerly drunk after dinner to assist digestion, generally from high narrow glasses.

MU'MIA, (from the Arabic *mum*, wax). MUMMY signifies *fissasphaltum*, *bitumen*, or a brown fluid found in sepulchres, in which bodies embalmed have been preserved many years; sometimes a carcass dried by the sun and sands, of the consistence of horn, and light, called white mummies. In general, the embalmed bodies from Egypt, preserved with peculiar care, swathed in linen, impregnated with bituminous matter, and adorned with hieroglyphics, have this appellation.

Mumia medullæ is the marrow of the bones. *Mumia elementorum*, a balsam of the external elements. (Paracelsus and Van Helmont.) *Mumia transmarina*, manna. Water deposited in a phial from breathing in it has the same appellation. *Mumia* sometimes means the subtle, spirituous, ethereal substance, supposed to be innate in every body, and to remain in some measure after death. The *mummy* taken from a human body is a resinous matter, hath a hardened, black, shining surface, is acrid and bitter to the taste, and of a fragrant smell. That which is particularly called *mummy* of the Arabians is a fluid liquor, obtained in sepulchres by exudation from carcasses embalmed with aloes, myrrh, and balsam.

MU'NDI A'NIMA, according to Plato, or rather his commentators, is a certain universal ethereal spirit, which exists perfectly pure in the heavens, as retaining its proper nature; but on the earth pervading elementary bodies, and intimately mixing with their minutest atoms, it assumes somewhat of their nature, and becomes of a peculiar kind.

" Spiritus intus alit, totosque infusa per artus,

" Mens agit molem, et magno se corpore miscet."

See ARCHÆUS, and ANIMA MUNDI.

MUNDIFICATI'VA, (from *mundifico*, to cleanse). Cleaning, detergent, purifying.

MUNDIFICATI'VUM PARACE'LSI. R. Mellis Britannici terebinthinæ Venet. ʒi. ʒss. vitel quatuor ovorum coq. ad consist. unguenti et sing. unciis adde hydrargyri nitrat. rub. ʒi.

MU'NDY-GUA'CU. See CATAPUTIA MINOR.

MUNGOS RADIX. *Ophiorrhiza mungos* Lin. Sp. Pl. 213. Its root is considered as a specific against the bites of mad dogs, and of the serpent *naya*. Its seeds are accounted among the febrifuges.

MUOI'DES, (from *μῶς*, a muscle, and *εἶδος*, likeness). See PLATYSMA MYOIDES.

MURÆ'NA. The generic name of the cel. See ALIMENT.

MURA'LIS, (from *murus*, a wall,) because it grows on walls. See PARIETARIA.

MU'RECI. A tree in Brasil, whose berries are purging. See Raii Historia.

MU'RIA, (from *μυρο*, to flow). BRINE, a solution of common salt: also a supposed acrimony in the fluids, resembling brine.

MU'RIAS, (from *muria*). MURIAT. Salt formed by the union of the muriatic acid with different bases.

MURIATIC ACID. See MARINUS SAL.

MURICA'TUS, (from *murex*, a prickly fish). The stalk of a plant covered with prickles like the shell of the murex.

MU'SA, (from the Arabic term *mauz*), *palma humilis*, *ficus Indica*, *bala*, *platanus*, the PLANTAIN TREE, *musa paradisiaca* Lin. Sp. Pl. 1477. Though called a tree, it scarcely merits the name of a shrub, since it hath an annual stalk like a reed. The leaves are an ell long, and three spans broad; of which it is supposed that Adam and Eve made aprons. The fruit is of the shape of a cucumber, of a yellow colour, and a most delicious food, and resembles meal and butter. The stalk is cut down to obtain the fruit, the spikes of which sometimes weigh fifty or sixty pounds. The fruit, when roasted, is beat in water, and the juice, styled *mislaw*, is drunk; and even the pulp, when dried and baked, may be used in the same way, to prepare the *mislaw*. It is found in all the eastern countries, and in Africa. See Raii Historia.

MU'SA FRU'CTU CUCUMERINO BREVIORI. See BANANA.

MU'SAM. See CASSADA.

MU'SCÆ HISPA'NICÆ. See CANTHARIDES.

MU'SCARI, (from the smell of its flowers). See BULBOS VOMITORIUS.

MUSCA'RUM FU'NGUS, (from *musca*, a fly). See BESONNA.

MUSCI'PULA, (from *musca*, and *capio*, to take). *Lychnis viscosa rubra*, *viscaria*. CATCH FLY grows among corn, and is cultivated in gardens. Its seeds are said to be warm and diuretic. See Raii Historia.

MUSCI'PULA PRATE'NSIS. See BEHEN ALBUM VULGARE.

MUSCULA'RIS ARTE'RIA, (from *musculus*, a muscle). See SCAPULARIE ARTERIÆ.

MUSCULA'RIS VENÆ. A branch of the posterior or upper branch of the external jugular; it spreads in the muscles, which cover the scapula and joint of the

humerus. Winslow describes it also as rising from the axillaris.

MUSCULI OBLIQUI SUPERIORES NERVII.
See PATHETICUS.

MUSCULO CUTANEUS NERVUS. See CERVICALES.

MUSCULORUM COMMUNIS MEMBRANA, MEMBRANA MUSCULOSA. Winslow denies its existence; but, in fact, it consists of compacted cellular substance, which, in finer ramifications, penetrates between the muscular fibres: in some places this membrane is closely united to the proper membrane of the muscles.

MUSCULOSI. A class of diseases, comprehending external or muscular inflammations.

MUSCULUS. See MYTILUS and CETUS. In anatomy from *μειν*, to draw or contract. LACERTULI, q. v. Muscles consist of those bundles of fleshy fibres by which the motions of all animal bodies are performed, and each is divided into the head, belly, and tail. The head is the part fixed on the immovable joint, called its origin, and is usually tendinous; the belly is the middle, fleshy part, which consists of the true muscular fibres; the tail is the tendinous portion inserted into the part to be moved, called the insertion; but in the tendon the fibres are more compact than in the belly of the muscle, and do not admit the red globules. The number and their nature are supposed not to differ.

The arteries, veins, and nerves, generally enter the middle of muscles, and ramify alike throughout their whole substance. The large arteries and veins run according to the direction of the muscular fibres; the less anastomose and run transversely: but a muscle seems to have a greater proportion of blood than is required for its nourishment, so that it probably assists in the performance of its functions.

The muscles are commonly attached to the bones, and the tendons are inserted into the substance of the bone; but when a muscle is fleshy at its insertion, it is only fixed to the periosteum. The muscles fixed to cartilages are attached to the perichondrium. Some are fixed to ligaments, as those in the fore arm; others into membranes, as those of the eye; and others again into fleshy parts, as those of the tongue.

Muscles are either oblong, hollow, or mixt; the oblong are divided into the rectilinear, half penniform, the penniform, the complex penniform, and the radiated. The muscular fibres are united very firmly in tendons, to lessen the bulk near the joint, which would have obstructed motion, and been otherwise inconvenient, as in the hand. By this means also the fleshy part of the muscle is nearer the centre of motion; and injurious friction is avoided. The appendices of muscles are, the fascia, or aponeurosis, the annular ligament, by which the tendons of some muscles are confined, and the sacculi mucosi.

The more intimate structure of the muscles has not yet been ascertained. The appearance of fleshy fibres is well known; and these, we have said, terminate in white, shining, firm cords, called tendons. The tendinous are seemingly the continuation of muscular fibres, losing, with their more compact structure, the peculiar muscular appearance. Yet this is contradicted on authority that we cannot lightly pass by, and it is said

that they are obviously distinct; that the muscular fibres are attached to, without being continued in, them; that they are arranged in a different manner, and inserted at angles more or less obtuse. On the other side, tendinous aponeuroses, diminishing in thickness, constitute internal aponeuroses, giving tension to the fibres, as external aponeuroses sometimes give points of attachment, and almost an origin, to muscles; nor can we deny that tendinous fibres may be inserted into muscles on one side, as they are to ligament or bone on the other. At the same time it is certain that tendons partake of none of the peculiar structure of muscles, and that they are more nearly allied to the simple solid.

Muscular fibres are, when carefully washed, white, solid, and parallel. It is said that they are indefinitely ramified; an opinion, observes Mr. Carlisle, which an hour's labour at the microscope will refute. On these fibres arteries very minutely ramify; it is said, also, with the same indefinable minuteness: but it is at least certain, that before they escape the assisted sight they cease to give off branches. The minuter ramifications of the nerves cannot be ascertained. They enter into the muscle often at right angles, at least considerable ones; and when they spread on the fibres they lose their external coverings, and become transparent, so that we can no longer follow them. The fibres are connected by a cellular substance of different fineness in different muscles, but apparently of a more delicate texture, as the muscular fibre itself grows more minute, and has very seldom any adipose accumulations.

From these facts, which are now well established, we may reject the opinion of the primitive muscular fibre being globular, spheroidal, or rhomboidal, of its being wholly nervous or arterial. We own that we have indulged the language of calling muscular fibres the sentient extremities of nerves, and occasionally spoken of them as such; but if we have at any time expressed such an opinion, we beg leave, on mature reflection, to disclaim it. If there were no other arguments, the proportion of bulk in the vessel and nerve, compared with that of the muscle, oppose it: the peculiar structure and other properties of the muscles are equally adverse.

Though muscles are evidently fibrous and red, we must not deny a muscular structure where we do not find red fibres. The lymphatic system is probably muscular; for the fibrous structure is discoverable in the thoracic duct of a horse: and Mr. Home has rendered it probable that the fibres of the crystalline lens are equally so. At least we know, in numerous instances, that muscular contraction takes place where fibres are scarcely, if at all, discoverable, and where the red muscular structure is not found. Yet, as a part of the fibrous structure, the muscles form a part of the primordial germ. We see their influence at the first dawn of life in the punctum saliens: their action is coeval with animation.

These facts at once disprove the theory of Girtanner, who attributes muscular contraction to a kind of explosion, or effervescence, arising from the oxygen in the blood uniting with the azot, the hydrogen, and carbon of the muscles; for contraction exists when azot is not yet formed. We admit that azot, which furnishes

the zoonic acid, is chiefly discovered in the muscles; that their fluids are the most completely animalized of the whole system; that in animals who lead the most active lives, and in the organs most constantly exerted, it is most frequently found, as in wild animals, the red deer, and hares, the pectoral muscles of the moor fowl, &c.; but this seems the effect rather than the cause of the contraction, as we shall soon find; and, on the contrary, the action of a lymphatic, for instance, is steady, and constant; that of the heart of the embryo rapid and unremitted, while each is transparent.

On what then does this action depend? certainly on one of those intricate states connected with life, which we cannot even approach by conjecture. We have nothing analogous to compare it with, nothing which possesses the same properties in different circumstances to enable us to divest it of the adventitious circumstances. We must content ourselves, therefore, with endeavouring to ascertain its phenomena and its laws.

We know, from various experiments, that a free circulation through the arteries of muscles is necessary to their contraction; for tying the artery will render a muscle paralytic; and even tying the inferior vena cava above the iliacs, we are told by Kaul Boerhaave, will render the muscles of the posterior extremities incapable of contraction. The free access of the nervous influence is equally necessary; for though we are vaguely told of animals without a nervous system possessing muscular power, none, which have been examined with care, are found to want this source of motion.

A muscle in action increases in absolute weight, in density, and in its power of resistance. That it increases in bulk may be doubted, for experiments are contradictory; and while the middle or the belly of the muscle is evidently enlarged, the diminution of its length compensates for the increase. Though the tendon is a firm, substantial cord, it is sometimes broken by muscular exertion; while the organ is uninjured, and the patella, as well as other bones, are fractured by a violent jerk, or a sudden, peculiarly violent, action of the muscles. It is, however, recorded, that the muscles themselves are sometimes ruptured, particularly the recti abdominis in tetanus, and the gastrocnemii in cramps; and, as it is difficult to suppose that increased cohesion should occasion a solution of cohesion, it has been suspected that this is the effect of the action of antagonists, or of unequal excitement. Neither, however, could be the cause in the present instances, nor is it difficult to conceive that the material may be ruptured by excess of power. Cord entwined with great force round any body, and then wetted, will be broken by the violent contraction. The choutchouc, a very elastic substance, is diminished in specific gravity by extension.

Muscular action, then, consists in an attraction of the parts of each fibre in a manner peculiar to animated nature. It is not a contraction in every dimension, since it would be then attended with diminished volume; but in length only attended with a proportional increase of bulk, so as to preserve the absolute volume unchanged, or perhaps somewhat increased. The force exerted by this contraction is enormous. It was calculated, however, by the mechanical physicians in the most extravagant manner, on foundations almost wholly chimerical; but on better grounds, from the very dis-

advantageous insertion of the muscles, which we shall soon enlarge on, to surmount a resistance of fifty pounds, the deltoid, it is said, must exert a force equal to 2568 pounds. In general, it appears that the force with which a muscle contracts is in proportion to the number of its fleshy fibres, and the extent of the surface to which these fibres are attached; but its degree of contraction, or the extent of its motion, is in proportion to their length. The limits of contraction differ in the long and in the circular muscles; for the former do not contract more than one third of their length; but the circular fibres of the stomach, which, in their utmost dilatation, may be expanded to a foot in circumference, will, after long fasting, be reduced to a circle of an inch. It must, however, be added, that in circular muscles no fibres pass completely round: bundles of fibres are collected, and end at different points, while some begin where others end. Each may, therefore, admit only of a limited contraction, while the dilatation just mentioned may be the sum of the whole.

Muscles are usually attached to bones near their joints, and, running almost parallel with the bone, are inserted at very acute angles. They are consequently levers of the third kind, situated between the fulcrum and resistance. By this contrivance, much force is lost to attain velocity, and to avoid deformity; for the muscle would start out in its action, if conducted in any other manner, and this starting would be in proportion to the celerity of the action of the resisting part. At present, the hand, for instance, sweeps through a large circle with great velocity, while the muscles, which raise the fore arm, viz. the biceps and brachialis internus, swell to a degree scarcely perceptible. In the force supposed to be exerted by the deltoid, a great proportion acts only in pressing the humerus to the shoulder, according to the common doctrine of the composition, and resolution of forces. Another loss of force arises from the oblique insertion of the fleshy fibres into the tendinous expansion, which pervades them: but, with the Author of Nature, power as well as life is obedient to the divine fiat, and each is profusely diffused: yet all this has been resolved into jarring atoms, molecules organiques, and animated filaments! Various contrivances, however, appear to have been adopted to lessen this considerable loss of power. In general, the extremities of the bones are enlarged, so that the muscle is removed from the parallelism, the tendons of the smaller line of direction of the bones are separated, or the angles at which they are inserted are augmented. Sometimes, for the same purpose, the tendons, or the muscles themselves, are reflected over pulleys. When the limb begins to move, the angle of insertion is, of course, increased.

The action of muscles is never intermitted, and only diminished in the sleeping state. This action arises from a less degree of that power which moves the limbs, and is styled, by Haller, the *vis insita*; by later authors, irritability, or tonic power. When muscles are not exercised, this power is very slightly exerted; but, by the position which the limbs assume, we discover the relative strength of the antagonizing muscles. Thus we find the flexors stronger than the extensors; for during sleep the head falls forward, the body, legs, arms, and fingers are lightly bent. We see the cause of

this strength, when we find that the flexors have stronger and more numerous fibres; that their insertion is farther from the centre of their motions, and under a larger angle, which, as we have remarked, must increase when flexion has begun. This superiority of the flexors bends the fœtus in utero into a round ball. When the infant is born, the same superior power of the flexors continues, though in a less degree, and frequent pandiculations are required, to give activity and energy to the extensors, which they again lose in advanced age. When we awake from a sound sleep the same yawning pandiculations occur; and Barthez fancifully refers the crowing of the cock, and the fluttering of his wings, to a similar purpose. It is always useful to examine, in diseases, the position of the limbs during sleep, particularly of children. If they deviate from the bent to a more straight position, there is generally some irregularity in the state of tone, and, of course, in the vital influx.

It is supposed by some authors, that the vital influx is not necessary to the contraction of muscles, but that they possess irritability as a quality, and this is the strict meaning of the *vis insita* of Haller; but we do not, in any instance, find this, for any time, unconnected with life. Irritability is, indeed, lost at different periods in different organs; for some, particularly the heart, soon lose it, while the voluntary muscles retain it; and apparently those which derive their nerves from the intercostal system lose it sooner than those whose nerves originate from the base of the cerebrum. Irritability is also exhausted in the agonies of death, and retained for a longer time when the death has been sudden and violent, except it happen from lightning. On this principle fish are crimped; for the muscles are cut across, while the irritability remains, and the muscular portions contract so as to give greater firmness to the flesh. To preserve this irritability, the fish receives a blow on the head as soon as it is taken from the water, when the operation is performed, is washed in hard water, whose astringency, from the selenite it contains, assists the contraction. Irritability is also soon destroyed by narcotic poisons, either if partially applied, or, more generally, if life is extinguished by their means. The power of contraction, by volition, by association, by a stimulus on the brain, or on the nerves in their course, as it acts through the medium of the nerves, is called the *nervous power*; though when volition only is the cause, Dr. Cullen chooses to call it the *animal power*. The *tonic power*, as we have said, is that state of constant contraction owing to life, or perhaps to the action of antagonizing muscles.

The state of muscles differs according to their vigour and their mobility. The first attends firm and robust, the second weak, constitutions. In the latter, muscular contraction frequently alternates with relaxation; and the greatest degree of this state is CONVULSIONS, vide in verbo. Vigorous contraction is less subject to alternate with relaxation; but such alternation is common to muscles in general, and found in every long muscle but among the round muscles in the heart, the intestines, probably also the stomach only. Spasm is not a disease of vigour, but of a high degree of irritation, and owing to an irregular influx of the vital power. We have enumerated association among the stimuli,

rather from a loose analogy than with strict pretensions to accuracy, including, in this way, each source of muscular action.

Muscular irritability is exhausted not only by exercise, by narcotic poisons, and every kind of excitement, but by mental exertions also: and the student, constantly at the midnight lamp, finds it greatly diminished, not only by his mental exercise, but by disuse. Violent emotions have a similar and more sudden effect. At the time we observe that violent muscular action diminishes, and occasionally destroys, sensibility. Thus, in battle, the soldier does not feel his wound; and the juggler violently contracts the muscles of his leg when he runs the pin into them. These facts, which might be supported by many analogous ones, seem to show that the sentient and moving powers are more closely connected than physiologists have supposed.

The bulk of a muscle is chiefly made up of cellular substance and blood vessels. When each is separated, the true muscular fibres occupy a very small space, and the muscles are found equally, often more, distinct in the emaciated invalid than in the robustest subject. We may conclude from hence, that muscular fibres are not destroyed nor produced; and we think the opinion is supported by observation. If a muscle is destroyed, the limb remains useless, or at least partially useful, by the assistance of those which remain. If cut through, the fibres are united by a compact cellular substance. Yet late authors have been fond of employing the analogy between the fibrin and the muscular fibre, particularly when they found the fibrin contract by the galvanic stimulus; and, in support of it, they quote an observation of Haller, that the generality of muscular arteries are curved on themselves, in a remarkable manner, when entering into the muscles. This structure, they think, must retard the blood, and facilitate the separation and deposition of the fibrin. The muscular flesh, they add triumphantly, is the most azotic fluid of the whole system, and the fibrin the most animalized portion of the blood. If, however, the fact be as just stated, that muscular fibres are not reproduced, this necessity no longer appears, and we know not that contraction is connected with azot. Irritability and sensibility are both, however, apparently peculiar to a fibrous structure; and we know so little of the means by which the nervous influence is connected with the nerve as a simple solid, that we may suppose this union in part depending on fibres, and, when these are formed, that they may share a portion of this incomprehensible power. Thus, then, the fibrin may enjoy a certain portion of life; thus the muscles may be more directly a part of the nervous system. Yet we have disclaimed both opinions; and, though the course of our argument has led us to this view of the subject, we must add that such reasoning appears loose and precarious. See BLOOD, vol. i. p. 357, &c. and NERVUS.

Before we proceed to a general enumeration of the muscles, we must premise, that the most fixed point is styled its origin, the more moveable its insertion. In the motion, however, of limbs, the peculiar muscles are not exclusively employed, since some distant ones are exerted to fix the part from which the muscles originate. In other circumstances the fixed point becomes

occasionally, though in a less degree, the moveable; and for this reason we have styled the origin the *most* fixed point. In some instances, the part from which the muscle originates is equally moveable with that into which it is inserted.

Muscles of the Head. The forehead is wrinkled and drawn upwards, as are also the eyebrows, by a broad thin muscle, *occipito frontalis*, which rises at the back part of the skull, and, covering the head, runs down the forehead, to be inserted into the skin of the eyebrows.

The eyebrows are drawn towards each other, and the skin of the forehead pulled down and made to wrinkle, as in frowning, by a pair of small muscles, *corrugatores supercilii*, which rise from the root of the nose, and are inserted into the inside of the eyebrows.

The ear is moved by eleven small muscles. The first three are called common, because they move the whole ear. The next five are termed proper, and only move the parts to which they are connected; while the other three are internal, to move the small bone situated within the ear.

The eyelids are closed by a muscle, which, rising from the inner angle of the orbit or cavity in which the eye is embedded, covers the under eyelid, then surrounds the outer angle, and passing over the upper eyelid, descends to be inserted, by a short, round tendon, near to its origin, *orbicularis palpebrarum*.

The eye is opened by a muscle, which, rising from the inner and upper part of the socket, is inserted into the upper eyelid, to draw it upwards, *levator palpebræ superioris*.

The eyeballs are carried through all their motions by six small slender muscles to each. They arise from the bottom of the socket, and are inserted into the outer coat of each eyeball at different points. Four of these move the eye upwards or downwards, to the right and to the left; while the two remaining muscles give oblique directions to the eye, at the same time protruding it; and all acting in quick succession, enable the ball of the eye to describe a complete circle. See *Oculus*.

The nose is affected by several small muscles of the face, but only one muscle on each side is proper to it. This muscle straightens the nostrils, and corrugates the skin of the nose, *corrugator naris*.

The mouth and lips are moved by nine pair of muscles, *levator labii superioris aëque nasi*; *levator anguli oris*; *zygomaticus major*; *buccinator*; *depressor labii superioris aëque nasi*; *depressor anguli oris*; *depressor labii inferioris*; *levator labii inferioris*; *orbicularis oris*; which, arising from the contiguous bones of the face, are inserted into the lips and angles of the mouth: and from the termination of these muscles a tenth is formed, which surrounds the mouth like a sphincter, and closes it, by drawing the lips together. It is from the actions of these muscles on the mouth, particularly at its corners, that the emotions of the mind are expressed, and the predominance of particular feelings in characters is indelibly stamped: unless in those individuals whom nature has gifted with an unimpressible dulness of character, or in whom the more delicate lines are filled up by too great fatness.

The lower jaw has four pair of muscles for pulling it upwards, as in manducation, viz. two pair seen upon the outside of the face, and two pair concealed by the angles of the jaw. The first pair arise from the sides

of the skull, above the temples, whence they are called temporal muscles, *temporalis*; and then descending under the bony bridges of the cheek bone, are inserted into the lower jaw near its ends. The second pair arise, at each side; from the under edge of the bony bridge, and descending along the cheek, are inserted into the angle of the lower jaw, *masseter*. These four muscles act powerfully in pulling the jaw upwards, and when we bite, may be felt swelling out in the flat part of the temple, and upon the back part of the cheek. The other two pair of muscles arise from the base of the skull, and are inserted into the lower jaw internally, for enabling this bone to move from side to side, the more effectually to grind the food, *pterygoideus internus* and *externus*. The lower jaw is pulled downwards by muscles, which extend between it and the bone of the tongue, and which also serve to raise the throat upwards.

Muscles of the Neck. The neck is covered with numerous and complicated muscles: those on the fore part or throat extend some between the head and upper part of the trunk, *latissimus colli* and *mastoideus*; others between the lower jaw and the os hyoides; more between this bone and the cartilages of the throat; while numerous other small muscles are situated between these cartilages and the trunk; and also about the root of the tongue and the back part of the mouth. Their names are sufficiently descriptive of their situations, viz. *omo-hyoideus*; *sterno-hyoideus*; *hyo-thyroideus*; *sterno-thyroideus*; *crico-thyroideus*; *digastricus*; *stylo-hyoideus*; *mylo-hyoideus*; *genio-hyoideus*; *genio-glossus*; *hyo-glossus*; *lingualis*; *stylo-glossus*; *stylo-pharyngæus*; *circumflexus*; *palati*; *levator-palati*; *palato-pharyngæus*; *constrictor isthmi faucium*; *azygos uvulæ*; *constrictor pharyngis superior*, *medius et inferior*; *crico-arytænoideus lateralis et posticus*; *arytænoideus obliquus et transversus*; *thyreo-arytænoideus*; *arytæno-epiglottideus*; and *thyreo-epiglottideus*. Their uses are, viz. to bend the head forwards; to open the mouth by pulling the lower jaw downwards; and to move the parts concerned in deglutition and speaking.

The muscles on the back part of the neck are rather portions of the great muscles, which cover the back, than distinct bundles of fibres; but, having some of their extremities fixed to the back part of the skull, and also to the hinder portion of the spine of the neck, are intended to move those parts, drawing them backwards and sideways.

Muscles of the Trunk. Those are principally the muscles which cover the breast; those which constitute the fore part and sides of the abdomen; and the great muscles that are spread over the back.

The muscles of the back are numerous and large: they arise from the whole length of the spine or back bone, having their originating fibres firmly fixed to the numerous processes or handles of that bone; from the upper and posterior edge of the pelvis; and also, some portions from the back part of the skull; and from these different organs, they spread over and cover the back of the trunk, and run to be inserted, some into the base of the arm, others into the spine at a distance from their origin, and the remainder into the ribs and back part of the skull. They consequently not only cover and protect the whole back part of the body, but also serve to pull the head backwards, move the whole arm,

assist respiration by acting on the ribs, and to raise the body by extending the spine. These are, the *trapezius*, or *cuticularis*; *rhomboideus*; *latissimus dorsi*; *serratus inferior et superior posticus*; *levator scapulae*; *splenius*; *complexus*; *trachelo mastoideus*; *rectus capitis posticus major et minor*; *obliquus superior et inferior capitis sacrolumbalis*; *longissimus dorsi*; *spinulis et semispinalis dorsi*; *multifidus spinæ*; *semispinalis colli*; *scalenus*; *interspinalis et intertransversales*.

The cavity of the abdomen is completed at its fore part and sides by a few broad and thin muscles, which extend from one bone to the other, having their ends firmly fixed to the edges of these bones; and passing over each other, to constitute walls for covering in and containing the bowels. These are *obliquus externus* and *internus*; *transversalis*; *rectus abdominis* and *pyramidalis*. These muscles also assist respiration by helping to expel the air from the lungs: and they contribute to the movement of the body, by bending it forward as in bowing, and by raising the pelvis.

The breast is covered by a few broad and strong muscles, which arise from the whole length of the breast bone, and form the fore part of the ribs, and running from each other over the chest, are inserted into the shoulder for moving the limb forward, *pectoralis major*; *serratus magnus*; *levatores costarum*.

The ribs are raised, and the cavity of the chest enlarged, during inspiration, by eleven double rows of small muscles on each side. They grow out from the lower edge of one rib, and are inserted into the upper rim of the next: *intercostales externi et interni*; *sternocostales*: at the fore part of the neck, close to the vertebræ, are the *rectus capitis internus, major, minor et lateralis*; *longus coli*.

Muscles within the Body. The principal one is called the diaphragm; it is a broad thin muscle, occupying partly a horizontal position, when the body is erect; but inclining downwards towards the back, and dividing the trunk of the body into the two great cavities, the thorax and the abdomen. It arises from the lower end of the breast bone; from the cartilages of the seventh, and of all the inferior ribs on both sides; and from the second, third, and fourth lumbar vertebræ; and from these origins its fibres run, like radii from the circumference to the centre of a circle, to be inserted into a broad flat tendon, which is situated in the middle of this muscle. The diaphragm is the principal agent in respiration, as shall be more fully described under that head.

The other muscles within the body arise from the sides of the lower end of the back bone, and from the inner surface of the pelvis, and, passing down to be inserted into the thigh bone, a little below its head, they help to turn the toes outwards, and to bend the thigh; or when the limb is fixed, they assist in bending the body, *psaos parvus et magnus*; *iliacus internus*; *quadratus lumborum*.

Muscles of the Superior Extremities. These anatomists divide into the muscles that are situated on the shoulder blade, on the arm, on the fore arm, and on the hand.

The muscles situated on the shoulder blade are called muscles of the arm, because, though they arise from the former bone, which serves them as a base, yet they are inserted into the bone of the arm to effect its

movements: the same observation holds with respect to the other divisions of these muscles.

The arm then is moved by seven muscles which arise from the shoulder blade, and passing over the joint are inserted into the arm bone at its upper and middle parts. The *deltoides*; *supra et infra spinatus*; *teres minor et major*; *subscapularis et coraco brachialis*; these, together with the muscles coming from the back and breast, already described, complete the motions of this part of the limb.

The fore arm is moved in flexion and extension by three muscles, which arise from the upper part of the arm bone; run down its whole length, and constitute its fulness and figure: they then pass over the elbow joint to be inserted into the upper ends of the two bones of the fore arm. These are the *biceps flexor cubiti*; *brachialis internus et triceps extensor cubiti*.

The hand is moved at the wrist by six muscles; three of these arise from the upper part of the fore arm, and descending along its whole length, are continued over the wrist, and are inserted into the hand close to this joint; they bend the hand, and are consequently called its flexors, *flexor carpi ulnaris*; *palmaris longus et flexor carpi radialis*. The three extensors, so called, because they extend the hand, and bring it backwards, arise from the lower end of the arm bone, and passing down the fore arm also, run to be inserted into the back of the hand just beyond the wrist, *extensor carpi radialis, longus et brevis*; *extensor carpi ulnaris*; all these muscles, before they reach to the wrist, become slender tendons, which is the cause of the tapering of the fore arm from about its middle to the hand.

Besides flexion and extension, the hand has a circular kind of motion called pronation and supination: the former takes place when we turn the palm down, as upon a table; the latter when we turn the palm upwards; and both motions are produced by four short muscles which extend obliquely across from one bone of the fore arm to the other, and roll the radius upon the ulna, carrying the wrist round in circles, *supinator longus et brevis*; *pronator radii teres et quadratus*.

The fingers are principally moved by two flexors and one extensor. The former muscles arise from the upper part of the fore arm near the bend, and running down towards the wrist, send off four round tendons each; which passing over the palm of the hand, are inserted, the one set of tendons into the upper part of the second bone, and the other into the last bone of each of the four fingers: the latter set of tendons pass through slits in the former, which help to bind them down, when the fingers are bent. The extensor muscle arises above the elbow, passes down the fore arm, and also splits into four round tendons, which can be plainly felt on the back of the hand, and are inserted into all the bones of the four fingers for extending them.

The other movements of the fingers, and those of the thumb, are performed by muscles, chiefly situated upon the hand; and which, together with those we have described, complete the motions of these parts. Except the *indicator* which extends the four fingers, the names express their uses. The *interossei interni et externi* extend the fingers, and move them in different directions. The *lumbricales* bend the first, and extend the two last, joints of the fingers.

Muscles of the Inferior Extremities. The great

muscles which move the thigh all arise from the pelvis, or the lower part of the trunk; covering, and also giving plumpness and shape to the external surface of these parts, they descend over the hip joint, to be inserted into the thigh bone below its articulating head: by the action of these powerful muscles the thigh is carried through all its motions. These are the *glutæi*; *pyriformis*; *gemi*; *obturator internus, et quadratus femoris*; *pectinalis*; *adductor longus brevis et magnus femoris*; *obturator externus*.

The leg is moved by eleven muscles, which arise partly from the pelvis, and partly from the upper end of the thigh bone: they descend along this bone, giving fulness and shape to the thigh, and passing over the knee joint, are inserted into the bones of the leg; the extensors into the upper edge of the knee pan, for extending the leg, and the flexors into the posterior sides of the long bones of the leg, a little below their heads: the tendons of these muscles form the inner and outer ham strings. *Biceps flexor cruris*; *semitendinosus*; *semimembranosus*; *tensor vaginæ femoris*; *rectus*; *sartorius*; *gracilis*; *vastus externus et internus*, *cru-reus et popliteus*. They bend the leg.

The foot is moved by three extensors, and by four flexors. The extensors arise, the two first by double heads from the lower end of the thigh bone, near the bend of the knee: these heads soon after unite into the great fleshy bellies, which, swelling out, form the calf of the leg; but decreasing where the leg begins to grow small, they each give off a broad thin tendon, which also uniting, form the tendon of achilles, to be inserted into the extremity of the heel. Those powerful muscles extend the foot by bringing it backwards, and are principally engaged in running, walking, leaping, &c. The third extensor of the foot arises also from the lower end of the thigh bone, and descending by a long, slender tendon, is inserted into the heel, to assist the former: but this muscle is sometimes not to be found in the human subject. *Gastrocnemius internus et externus*; *plantaris*.

The four flexors arise, the two first from the upper part of the tibia, or principal bone of the leg, and continuing fleshy about half way down that limb, send off two round tendons, which pass under the inner ankle, and are inserted into the bones of the foot. The other two flexors of the foot arise from the superior part of the fibula or smaller bone of the leg, and sending off two round tendons, which pass under the outer ankle also, are inserted into the bones of the foot. These assist the former in bending the foot by drawing it upwards. *Tibialis posticus et anticus*; *peronæus longus et brevis*.

The toes have two extensors and three flexors. The first extensor arises from the upper part of the leg, and descending to the ankle, splits into four round tendons, which run forward upon the upper part of the foot, where they can be plainly felt, and are inserted into the four small toes to extend them: the other extensor arises from the heel, and running forward upon the foot, also splits into four tendons, to be inserted into the toes likewise, and to assist in extending them.

The flexors of the toes arise, the first from the under and back part of the heel, and running forward along the sole of the foot, sends off four tendons to be inserted into the second row of bones of the four smaller

toes. The second flexor arises from the back part of the tibia below its head, and descending the leg, passes at the inner ankle to run along the sole of the foot, on the middle of which it splits into four slender tendons, which perforate the former, in the manner of those which bend the fingers; and extending beyond them are inserted into the extremities of the last joint of the four small toes. The third flexor assists the two former in bending the toes, and also draws them inwards. Besides these there are other small muscles which are situated upon the foot, and which, with those coming from the leg to be inserted into the great toe, complete the movements of these parts. These muscles are sufficiently known by their names, and what has been said on those of the hand.

Thus we see that the muscles or flesh cover and spread over the whole frame of bones, connecting and securing its different divisions and parts; and not only producing all its movements, but also giving to it fulness, shape, and beauty.

See the Croonian Lectures in various volumes of the Philosophical Transactions; Haller's *Elementa Physiologiæ*; Brown on the Muscles; Winslow's *Anatomy*; Cowper's and Albinus's *Tables of the Muscles*; Innes and Douglas on the Muscles.

MU'SCULUS ANTERIOR MALLEI, or MU'SCULUS EXTERNUS AU'RIS DUVERNII; *anterior malleolus*; is placed in a fissure on the temporal bone, above the glenoid cavity, where the lower jaw plays, runs inward, and is inserted into the Ravian process of the malleus irregularly forward from the incus; and by taking off from the vibratory motion of the bones, it is supposed to fit the ear for receiving weaker sounds.

MU'SCULUS EXTERIOR. See ABDUCTOR OCULI.

MU'SCULUS INFERIOR. See DEPRESSOR OCULI.

MU'SCULUS TUBÆ NO'VUS VALSALVÆ. See CIRCUMFLEXUS PALATI.

MU'SCUS CLAVATUS. See LYCOPodium.

MU'SCUS CUMATILUS. *Lichen aphthosus* Lin. Sp. Pl. 1616, is supposed to be anthelmintic, and is given in infusion or decoction to destroy worms, or to remove aphthæ. The dose of the powder is twelve grains to infants. Its smell is highly fetid and disgusting.

MU'SCUS ARBOREUS, *lichen plicatus* Lin. Sp. Pl. 1622, *usnæ officinarum*. It is slightly astringent, used to stop hæmorrhages, and by the Laplanders to relieve excoriations from travelling.

MU'SCUS LAPIDEUS. See CORALLINA.

MU'SCUS PULMONARIUS. *Pulmonaria arborea*, OAK LUNGS, and LUNG WORT, is made up of flat, wrinkled, rough leaves, greenish above, and ash coloured underneath, with several round, reddish brown spots on the surface, in which the seed is supposed to lie. It hath a bitterish astringent taste, and grows spontaneously on the oak tree.

MU'SCUS PYXIDATUS, *musculus pyxoides terrestris*, *lichen pyxidatus major*; *lichen cocciferus* Lin. Sp. Pl. 1618. CUP MOSS, a species of lichen, growing on barren dry ground, with many hoary whitish green, small leaves, spread on the surface of the earth, among which arise little, whitish, dusky, hollow cups, a quarter of an inch high, showing neither flower nor seed. The decoction is reckoned a specific in the hooping cough.

MU'SCUS SQUAMOSUS TERRESTRIS. See LYCOPodium.

-MUSTELA'NEI. See ANCI.

MU'STUM, (vinum mustum, i. e. -novum, from *μοσχος*, *tener*). MUST, *gleucos*. This term usually given to new wine, is now applied to the saccharine juice of several fruits, susceptible of the spirituous fermentation, and particularly of grapes, before its commencement. When boiled till one third is consumed, it is called *carænum*; when to one half, *defrutum*; *hefsema*; and when its fermentation hath been prevented, or prematurely suppressed by fumigation with sulphur, *stum*. See VINUM.

MU'STUS, (from *μοσχος*, *tener*). The WHITE CALX OF URINE, and whatever is young or tender, as *virga musta*, *agna musta*.

MUTELLI'NA. See MEUM ALPINUM GERMANICUM.

MUTI'LLA. The velvet ant of South America, highly troublesome from its sting. It is usually found in sandy places, runs very swiftly, and lies concealed under stones and flowers. There are many European species, but these are not troublesome.

MU'TITAS, (from *mutus*, *dumb*). DUMBNESS. The want of power to articulate words. Dr. Cullen places this disease in the class *locales* and order *dyscinesia*, defining it an inability of articulating words. The species are,

1. MU'TITAS ORGANICA; when the tongue is taken away or injured.

2. MU'TITAS ATONICA, when the nerves are chiefly affected.

3. MU'TITAS SURDORUM, from early deafness.

MYACA'NTHA, (from *μυς*, a mouse, and *ακανθα*, a thorn; because its prickly leaves are used to preserve substances from mice). See RUSCUS.

MYA'GRO, and MYA'GRUM, (from *μυια*, a fly, and *αγρευω*, to seize; because flies are caught by its viscidty). *Myagrurn perenne* Lin. Sp. Pl. 893. (See RAPISTRUM.) This plant has a turbinated fruit, like an inverted pear, unicapsular, pressing in the stalk, containing one seed, with two empty cells, resembling in virtue the rapistrum, or raphanistrum.

MY'CE, (from *μυω*, to wink.) A WINKING, CLOSING, or OBSTRUCTION. It is applied to the eyes, to ulcers, and to obstructions of the viscera, especially the spleen. In botany it means a fungus; in surgery the fungus which rises in ulcers or wounds. In some authors it signifies a yellow vitriol.

MYCHTHI'SMOS, (from *μυχθίζω*, to mutter or groan). A sighing or groaning during respiration, while the air is forced out of the lungs. Hippocrates.

MYCONOI'DES, (from *μυκλον*, a nostril, and *ειδος*, resemblance). An epithet of an ulcer, which is full of mucus.

MY'CTER, (from *μυσσω*, to blow the nose). See NASUS.

MY'CTERES. See NARES.

MYDE'SIS, (from *μυδαω*, to abound with moisture). A disease of any part from redundant moisture, applied by Galen to the eyelids.

MY'DON, (from *μυδαω*, to grow putrid). Fungous flesh in a fistulous ulcer.

MYDRI'ASIS, (from *μυδαω*, diseases supposed to arise from too great influx of humours). Different complaints have been attributed to this cause, the distinguishing symptom of which is a dilatation of the pupil.

pil. These are amaurosis, hydrocephalus, worms, the adhesion of the uvea to the capsule of the crystalline, paralysis and spasm. See AMAUROSIS.

MYLA'CRIS, (from its resemblance to *μυλη*, a grinding-stone). See PATELLA.

MY'LE, (*μυλη*). See PATELLA and MOLA.

MYLO-GLOSSI, (from *μυλη*, *dens molares*, and *γλωσσα*, *lingua*). These muscles are small fleshy planes, situated transversely on each side, between the ramus of the lower jaw and the basis of the tongue; they rise from near the inner side of the dentes molares, and thence run to the basis of the tongue, but are often wanting.

MYLO-HYOI'DES, (from *μυλη*, a grinding tooth, and *υοιδης*, the hyoid bone,) muscles which rise with a large basis from the inferior part of the lower jaw, and are inserted at the basis of the os hyoides.

MYLO-PHARYNGÆ'I, (from the same, and *φαρυγγει*, the pharynx,) *cephalo pharyngæi*. See GENIOPHARYNGÆI and PHARYNX.

MY'LO'N. See STAPHYLOMA.

MYOCE'PHALON, (from *μυια*, a fly, and *κεφαλη*, the head). A tumour in the uvea of the eye, resembling the head of a fly. See STAPHYLOMA.

MYOCOILI'TIS, (from *μυων*, *musculus*, and *κοιλια*, *venter*). An inflammation of the muscles of the belly. (Vogel). See INFLAMMATIO MUSC. ABDOMINIS.

MYOLO'GIA, (from *μυς*, a muscle, and *λογος*, *sermo*). A treatise on the muscles.

MYO'PIA, MYOPI'ASIS, (from *μυω*, to shut, and *οψ*, the eye). SHORT SIGHT; *dysoptia dissitorum* of Cullen; *nuciositas*, because the eyes are generally partly closed. This disease is owing to the excessive convexity of the crystalline, by which the rays, unless the object is placed close to the eye, are united before they reach the retina; consequently vision must be indistinct. This convexity may arise from a beginning hydrophthalmia, or a too copious secretion of the aqueous humour; from a distention of the axis of the eye, in consequence of habit; from a natural (often an hereditary) convexity of the anterior curvature of the crystalline; from the density and, in consequence, the increased refractive power of the cornea. The increased convexity of the cornea is not uncommon in the infant state. The concavity of the spectacles must be proportioned to the sight, and myopes should begin with the least concave glasses. When they read they should never use them. See AMBLYOPIA, and OCLUSUS.

MY'OPS. Short sighted person.

MYORE'SHALON. The uvea growing over the sight.

MYO'SIS, (from the same). A contraction of the pupil, not enlarging in darkness. This sometimes arises from spasm, occasionally from paralysis, and in the internal ophthalmia, or from wounds, from inflammation, when it is, perhaps, ultimately referrible to spasm. It is sometimes like the myopia acquired, sometimes hereditary.

MYOSI'TIS, (from *μυς*, a muscle). Rheumatism, particularly when it affects the muscles of the limbs proceeding from the joints. (Sagar.) See RHEUMATISMUS.

MYOSU'ROS, (*μυς*, a mouse and *ουρα*, a tail; from its resemblance,) *cauda muris*, *holosteum*, *holostes*, *ranunculus*, *myosurus*, *minimus* Lin. Sp. Pl. 407. Mouse

TAIL. The leaves are gramineous; it flowers in May, and grows in the highway, resembling in virtue the plantain.

MYOTO'MIA, (from *μῦς*, a muscle, and *τεμνω*, to cut). A dissection of the muscles.

MYRE'PSICUM O'LEUM. See BEN.

MYRICA, (from the Hebrew, *marak*). See TAMARISCUS.

MYRICA GALE. See MYRTUS BRABANTICA.

MYRIOPHYLLON. See MILLEFOLIUM.

MYRI'NGA, MY'RINX. See AUDITUS.

MYRI'STICA NUX, (from *μυρον*, an odoriferous ointment; named from its sweet smell). See NUX MOSCHATA.

MYRME'CIA, (from its being the size and shape of *μυρμηξ*, a *mismire*). A soft, often a moist, wart, about the size of a lupine, with a broad base, growing on the palms of the hands, or on the soles of the feet, deeply rooted and painful.

MYROBA'LANI, (from *μυρον*, an ointment, and *βαλανος*, a nut,) MYROBALANS, a dried fruit of the plum kind, brought from the East Indies, of which three kinds are brought from Bengal, *fabā Bengalensis*, *Cambaia*, and *Malabarica*. (See ADIPSOS.) They have been recommended as somewhat astringent and tonic, but are not now in use. Myrobalanus means *nux*, or *glans unguentaria*, a NUT or ACORN, fit for making precious ointments; for from the myrobalans described by Dioscorides, Pliny, and Galen, they used to express a fragrant oil used in ointments. All the different kinds, which we hasten to describe, are probably varieties of the *phyllanthus emblica* Lin. Sp. Pl. 1393.

MYROBA'LANI BELLI'RICI, *belleregi*, *bellegu*, BELLIRIC MYROBALANS, are of a yellowish grey colour, and an irregularly roundish or oblong figure, about an inch long, and three quarters of an inch thick.

MYROBA'LANI CHEBULÆ resemble the yellow sort in their figure and ridges, but are larger and darker coloured, inclining to brown or blackish, and with a thicker pulp.

MYROBA'LANI CITRI'NI, vel FLAVI, are somewhat longer than the belliric, have generally five large longitudinal ridges, and as many smaller between them, somewhat pointed at both ends.

MYROBA'LANI E'MBLICI, *ambegu*, are of a dark, blackish grey colour, roundish, about half an inch thick, with six hexagonal faces opening from one another.

MYROBA'LANI I'NDICI, vel NIGRI, *asuar*, are of a deep black colour, oblong, octangular, differing from all the others in having only the rudiments of a stone, and supposed to have been gathered before maturity.

All the sorts have an unpleasant, bitterish, austere taste, strike a black colour with a solution of vitriol, contain tannin, are gently purgative and astringent. The dose in substance is from $\frac{3}{4}$ i. to $\frac{3}{4}$ ss. in infusion or decoctions from $\frac{3}{4}$ ss. to $\frac{3}{4}$ i. ss. Water extracts their stypic virtue, and the extract is astringent. The *fabā Bengalensis*, or the Bengal bean, is an abortive fruit of the myrobalans, round, flattish, wrinkled, and of the size of a small fig, hollow in the middle, of an irregular shape, hard, tough, brown outwardly, and blackish within, of but little smell, but an austere and astringent taste. It is vitiated by the puncture of an insect, by which it is often hollowed like a gall; but is a powerful astringent,

and is said to be demulcent. See Raii Historia; Tournefort's Materia Medica.

MYROBA'LANUS ZEYLA'NICUS. See ELEMI.

MY'RON, (from *μυρον*, to flow). An ointment, medicated oil, or unguent.

MYROPHY'LLON. *Millefolium aquaticum*. WATER FENNEL, grows in marshy soils; flowers in April and is styled vulnerary. See Raii Historia.

MYRO'XYLON, (from *μυρον*, an ointment, and *ξυλον*, wood; because it flows from a tree). See PERUVIANUM BALSAMUM.

MY'RRHA, (from Hebrew, *mar*, bitter). MYRRH, *stacte*, *ergasma*, in the ancient designation, Z z. Dioscorides mentions a fatty species, *gabireca*. It is a gummy resinous concrete, brought immediately from Alexandria, Smyrna, and Aleppo, said to be a produce of the *scandix odorata*; found, according to Bruce, in that part of Africa to the south of the straits of Babel-Mandel. When he inquired after the plant which produced it, they constantly brought him the branches of the *acacia nilotica*. Loureiro has told us that it is the production of a species of *laurus*, but this is improbable; and from its sensible qualities, it seems rather to belong to the genus *amyris*. It is brought to us in globules, or drops, of various colours and sizes. That of a reddish brown colour, not verging too much to a yellow or black, uniform on the outside, internally speckled or streaked with white, semicircular striæ, clear and bright, somewhat unctuous to the touch but not so tenacious as to stick to the fingers, is the best. If whitish, or dark, resinous, fetid or mixed with impurities, it should be rejected.

This drug is subject to a variety of frauds; it is mixed with hard, shining, yellow pieces of a gum, void of smell or taste. Pieces of bdellium are found with it, known by their darker colour, their being soft within, and by their different smell and taste. Sometimes an unctuous gummy resin, of a moderately strong, somewhat ungrateful, smell, and a bitterish, very durable taste; obviously different both from those of bdellium and myrrh; at others, pieces of a hard, compact, dark coloured kind of tears, less unctuous than myrrh, of an offensive smell, a most ungrateful bitterness, and of a very resinous nature, are mixed with it. The myrrh itself is sometimes blackish, gathered probably from old trees, and fitter for tinctures; or yellow, apparently from young trees. The latter easily dissolves in the mouth, hath a much more agreeable aromatic smell, and is preferable for pills, powders, and watery solutions. All the variety seems, according to Bruce, to arise from the age of the tree, and the period of collecting.

Myrrh is said to be balsamic, vulnerary, antiseptic, attenuant, and deobstruent; but its real virtues seem not to be clearly understood. It is a bitter, apparently of the narcotic kind, and in doses from ten to fifteen grains appears to be mildly corroborant, and gently sedative. That it promotes the secretions is doubtful, but its having been so frequently given as an emmenagogue seems to show that it has some power in promoting this discharge. We find it reprobated by the French physicians, as promoting bloody urine; and we have confessed some prejudice against it in hectic where hæmoptoe had occurred, or was dreaded. In cases of languid circulation and cachexy, it seems to be useful rather as a tonic than as a stimulant; and it seems

occasionally of service as an antispasmodic. In external sores it is a mild sedative, and frequently an antiseptic application; effects which perhaps recommended it to internal use in hectic. In doses of from half a drachm to two scruples it is said to be stimulant; but such we have never given. In some states of low fever, however, it seems occasionally to act as a cordial.

It dissolves almost totally in boiling water; but as the liquor cools, the resinous part subsides; and if the solution is evaporated to an extract, the bitter of this drug only remains. By distillation with a boiling heat in water, the whole of its flavour rises, partly impregnating the distilled water, and partly collected and concentrated in the form of an essential oil, in smell extremely fragrant, and more agreeable than the myrrh in substance; in taste remarkably mild, and so ponderous as to sink in water. Two or three drachms of this oil are obtained from $\frac{3}{4}$ xvi. of the gum. Rectified spirit dissolves less of the myrrh than water; but it extracts more perfectly that in which its bitterness, flavour, and virtue consist. The spirituous solution contains all the active matter; in distillation nothing is carried away by the spirit, so that the extract obtained from a spirituous solution is a very fragrant, bitter, tenacious resin, and possesses all the virtue of the myrrh.

From 7680 parts of myrrh Neumann procured 6000 of watery extract, 180 of volatile oil, and 720 of alcoholic extract: by inverting the order, 2400 of alcoholic and 4200 of watery extract. Myrrh is not fusible, and with difficulty inflammable, soluble in alkalis; but the tincture poured into water becomes yellow and opaque. The watery solution, when filtered, is also yellow. Myrrh was anciently of great value, not as a medicinal substance, but as one of the ingredients for embalming.

The London College directs the tincture of myrrh to be prepared by adding three ounces by weight of bruised myrrh to a pint and half of proof spirit, and half a pint of rectified spirit of wine. It must be digested with a gentle heat for eight days, and strained. This tincture is frequently employed in detergent gargles (see APHTHÆ); but if one ounce of hepatic aloes be added it becomes the *tinctura myrrhæ cum aloë*, and is applied externally to ulcers as a vulnerary, and is useful when such are foul and fetid, requiring stimulating applications.

Elixir myrrhæ compositum. *Tinctura sabina composita*, is made by adding one ounce of the extract of savin to tincture of castor, one pint; tincture of myrrh half a pint. Digest until the extract is dissolved, and strain. (Pharm. Lond. 1788.) This was formerly called *elixir uterinum*; and is given in a dose of from twenty to forty drops, in a cup of pennyroyal tea, twice a day. It is esteemed a good emmenagogue, possessing similar virtues to the powder and extract of sabine.

Pulvis è myrrhæ compositus. Take of the leaves of dried rue, savin, myrrh, and Russia castor, of each an ounce; mix and beat them into a powder (Pharm. Lond. 1788). Given in a dose of twenty-five or thirty grains two or three times a day, it is esteemed an efficacious medicine, in uterine obstructions, and hysteria.

Pulvis myrrhæ added in an equal proportion to the lapis calaminaris is sometimes sprinkled upon an ulcer, to promote cicatrization.

Oleum myrrhæ per deliquium. Boil an egg very hard,

take out the yolk, and fill the cavity with myrrh, bind the divided sides together, and it will deliquesce in a cool moist atmosphere.

It possesses all the smell and taste of the myrrh, may be precipitated and coagulated by spirit of wine, and the coagulum dissolved by water. It is used as a cosmetic. See Raii Historia; Tournefort, Lewis, and Cullen's Materia Medica; Neumann's Chemistry.

MYRRHA. See ANIME.

MYRRHINE, (because it smells like myrrh). See MYRTUS.

MYRRHIS, (from its smell). *Cerofolium Hispanicum*, *conile* from its resemblance to hemlock, *cicutaria odorata*, SWEET CICELY, GREAT CHERVIL, *scandix odorata* Lin. Sp. Pl. 368. The petals are unequal, the seeds striated, resembling the beak of a bird. In virtue it agrees with chærefolium, resembles in taste the cloves, and, like them, is said to be useful in scurvy. The branches resemble those of fern, with a pleasant aromatic smell, the stalks hairy, the flowers white, and appear in May or June. It is rather an esculent than a medicinal plant, though said to be diuretic. See Raii Historia.

MYRRHIS A'NNUA. See DAUCUS CRETICUS.

MYRRHIS SYLVESTRIS. An appellation of the *chærophyllum sylvestre*, &c.

MYRTACANTHA, (from its likeness to myrtle, and from its prickly leaves). BUTCHER'S BROOM. See RUSCUS.

MYRTIDANON, (from *μυρτος*, the myrtle). According to Hippocrates this is the fruit of the Indicum, called from resembling myrtle berries, which the Indians called pepper. But Dioscorides means by it an excrescence which grows on the trunk of the myrtle, more astringent than the plant itself.

MYRTILLI, (a dim. of *myrtus*). See MYRTUS COMMUNIS ITALICA.

MYRTICHEILIDES, (from *μυρτος*, the clitoris, and *χειλος*, a lip). See NYMPHÆ.

MYRTON, (from its resemblance to the myrtle berry). See CLITORIS.

MYRTUS. The MYRTLE; *myrrhine*, because it smells like myrrh.

MYRTUS BRABANTICA and ANGLICA, called also *rhus myrtifolia Belgica*, *myrica gale* Lin. Sp. Pl. 1543, *rhus sylvestris*; *acaron*; *frutex odoratus septentrionalium clæagnus chamelæagnus Dodonæi*. GAULE, SWEET WILLOW, DUTCH MYRTLE, is a small shrub much branched, with smooth, oblong, whitish green leaves, somewhat pointed, or converging at each end; among which arise pedicles, bearing scaly cones, which include the seeds, one little seed being lodged in each scale. It grows wild in uncultivated watery places, in many parts of England, flowers in May or June, ripens its seeds in August, and loses its leaves in winter. The leaves, flowers, and seeds, have a strong fragrant smell, and a bitter taste: they are used to destroy moths and cutaneous insects; sometimes to preserve malt liquor; but they render it very inebriating. An infusion taken inwardly is said to destroy worms, and strengthen the stomach. This plant has been highly esteemed, but is little valued in this kingdom. See Raii Historia Plantarum; Lewis's Materia Medica.

MYRTUS COMMUNIS ITALICA. COMMON MYRTLE; *myrtus communis* Lin. Sp. Pl. 673, var. γ , is an

evergreen shrub, with oblong leaves, pointed at both ends, in the bosoms of which spring solitary white pentapetalous flowers, followed by black, oblong, umbilicated berries, full of white crooked seeds. It is a native of the southern parts of Europe; the berries, which are called *myrtilla*, rarely come to perfection with us, and they are usually supplied by those of the *vaccinium myrtillus* Lin. Sp. Pl. 498.

The berries are recommended in alvine and uterine fluxes, and disorders from laxity and debility; they have a roughish, not unpleasant, taste, and are accompanied with a sweetish aromatic flavour. The leaves are astringent, and, if rubbed, yield an aromatic flavour. See Raii Historia; Lewis's Materia Medica.

MYRTUS PIMENTA vel JAMAICENSIS. See PIPER JAMAICENSIS.

MYSTAX. That part of the beard which grows on each side of the upper lip. The etymon of *mus-tachio*.

MYSTICE'TUS. See CETUS.

MY'TILUS. The MUSSEL, *mytilus edulis* Lin. Syst. Naturæ, *musculus*. A sea shell fish of a luscious flavour, found on many parts of our coast, of a moderate size, larger between the tropics, and smaller in the arctic sea. As from mushrooms, so from this shell fish very alarming symptoms are often produced, ascribed to a quality in the mussels, either proper to them, or accidentally acquired from their situation or nourishment. The pea crab, often found in them, has been accused; but as similar effects are observed to arise from various other causes besides mushrooms and mussels, the peculiarity of the person's constitution is generally supposed to occasion them. Similar complaints have sometimes been produced by eating salmon, taking the Peruvian bark, by washing the hands in water after fish hath been boiled in it, bathing in the sea, cantharides applied to the skin, and the internal use of wild valerian root.

"The signs which announce the noxious effects of boiled mussels," observes an author in the second volume of the Memoirs of the Academy at Brussels, "are an universal uneasiness, or numbness, that commonly takes place three or four hours after they have been eaten. These symptoms are succeeded by a tightness of the throat, a sense of heat about the head and eyes, immoderate thirst, nausea, and sometimes vomiting. If the patient hath the good fortune to vomit up the whole of the offensive matter, this evacuation is generally sufficient to stop the progress of the complaint; but if he does not bring up any or only part of the noxious substance, the disorder becomes more or less alarming, according to the quantity of the deleterious matter in the first passages, and the particular constitution of the patient. The want of a sufficient evacuation, by vomit, increases the tightness of the throat, and the swelling of the face, eyes, and tongue: all the parts within the mouth appear inflamed, and, as it were, excoriated; and the redness soon spreads to the outer surface, appearing first in the face, and extending from thence to the neck, breast, and abdomen, and by degrees over the whole body. This particular eruption is the symptom the most distinguish-

ing and characteristic of the malignancy of mussels; it is constantly accompanied with a kind of delirium, with singular uneasiness, and an insupportable itching. It has no affinity with the eruption produced by the erysipetalous fever, with the scarlatina, measles, purpura urticaria, or any other known species of red eruption; but has these particularities, viz. that it never appears unless mussels have been eaten; is not preceded by fever, or accompanied by symptoms which appear united in any other disease; and lastly, that the whole surface of the body, though redder than in any other eruptive disease, appears as it were spotted with an infinite number of points of a deeper red than the rest of the skin. These points are infinitely smaller than a millet seed; if we examine them through a lens, we see distinctly that they are the opening or pores of the cuticle, while the redness which is seen only through the epidermis appears of a paler hue."

The proper treatment of these complaints is the same with that directed when mushrooms are the offending cause. (See AMANITA.) The itching is considerably allayed by washing the whole surface of the body with vinegar and water for about half an hour.

It is advised as a preventive of their injuries to wash them with water, and afterwards with vinegar, to boil them for use in an earthen pot with vinegar and water, and a few grains of Jamaica pepper.

The dangerous consequences supposed to arise from eating mussels are, however, greatly exaggerated. They very rarely occur, and scarcely with the violence just described; and, though such effects are occasionally heard of, yet years elapse without such an occurrence, on coasts where mussels are a common article of food. These deleterious consequences are sometimes attributed to one particular part of the fish; at others, to their lying on beds of cupreous pyrites; sometimes to their richness, at others to a peculiarity of constitution. No part of the fish, however, seems to have been pointed out, the absence of which would secure the person from the peculiar effects: the symptoms are not those which follow the swallowing of copper, and the fish is not peculiarly rich. It is certainly more deleterious to some constitutions than others. M. Debeunne thinks that the cause is the spawn of the star fish (the asteria), and has added some experiments in a late volume of the Journal de Physique to support his opinion. This is by no means improbable; but the little crabs often found in mussels are far from being unwholesome.

MYTTO'TUM. A kind of food made of garlic, onions, and cheese, bruised together.

MYU'RUS, (from *μῦς*, a mouse, and *οὐρα*, a tail). An epithet for a sinking pulse, when the second stroke is less than the first, the third than the second. The pulse sometimes sinks irrecoverably, but occasionally rises again in some degree.

MYXAS, MYXA'RIA, (from its viscosity, resembling *μύξα*, mucus). The *sebastina domestica*, cordia *myxa* Lin. Sp. Pl. 273. See SEBESTEN.

MYXOSARCO'MA, (from *μύξα*, mucus, and *σάρξ*, flesh). See MUCOCARNEUS.
